SURVEYING.

Surveying.

THE system of rules and operations by which the relative position of any number of points in a tract of country may be determined, so that it may be delineated on a plane surface, is called surveying. When the extent of country is not great, the subject involves little difficulty; but when a kingdom, such as Britain or France, is to be surveyed, in addition to some of the more profound theories of pure mathematics, the aid of astronomy, and other branches of natural philosophy, is required; but such an extensive view of the subject will not be expected in this work.

As a surveyor has perpetual occasion for calculation, it is necessary that he be thoroughly master of arithmetic, and understand the nature of logarithms, the use of logarithmic tables, and algebraic notation. As it is his business to investigate and measure lines and angles, and to describe them on paper, he should be well acquainted with the elements of geometry and trigonometry, and with the application of their principles to the mensuration of heights, distances, and surfaces. In particular, he should be familiar with the best practical methods of solving the ordinary geometrical problems, and should be expert in drawing lines and describing figures. He should know something of the principles of geology, optics, and magnetism, and possess some skill in drawing and painting.

In a survey, the most remarkable objects, such as the summits of hills, spires, towers, &c. must be chosen as stations, and, if necessary, marked by signals. These must be considered as joined by straight lines forming a chain of triangles, each connected with all the others. The angles of the triangles should neither be very acute nor very obtuse; their sides should be as long as possible, so as to admit of two of the stations, at the angles, being seen from the third: the nearer each triangle approaches to the equilateral form, the better. The three angles of each triangle should be measured, if possible, for although two of them be sufficient to determine the third, yet it will conduce to accuracy if all the three be taken; and if their sum hardly differ from 180°, it may be supposed that they have been correctly determined. The principal points should also be intersected as much as possible by lines from different stations, to ascertain whether different data give the same position.

Surveying.

A theodolite is the most convenient instrument for measuring the angles, because it gives them at once reduced to the plane of the horizon. When a sextant is used, the angles, if out of that plane, must be reduced to it by calculation.

Supposing a proper disposition of the triangles to have been made, when their angles are known, if a side of any one of them were also known, then the sides of all the others might be found by calculation, and a plan of the country constructed. Therefore, a side of one of the triangles must be taken as a base, and measured with great care, for upon this the just determination of the absolute length of all the other lines depends; and if the survey be extensive, it will be proper to assume another base, called a base of verification, and compare its measured with its calculated length. The base should be as long as possible, and lie on a flat surface; if it is not perfectly level, its slope must be measured, and its horizontal length calculated. In ordinary cases, the base may be measured by a chain or tape, but more accurately by stretching a rope, 100 yards or more, tight in its direction, and applying repeatedly to it a twenty-feet deal-rod. A pin may be stuck in the rope at the fore-end of the rod, each time it is removed, and before the rope is removed to a new position: a point directly under the end of the last rod may be marked on the top of a peg fixed in the ground. In the trigonometrical survey of Britain, which has been going on ever since 1784, under the direction of the Board of Ordnance, an original base of about five miles was measured three times over, first with twenty-feet deal-rods, then with glass rods of the same length, and at a later period by a hundred feet steel chain of a particular construction. Several bases of verification have also been measured. The labour and ingenuity exerted in these operations have been very great.

As, generally speaking, all bodies expand by heat and contract by cold, a rod or chain varies in absolute length as it varies in temperature. A steel rod at the temperature of water boiling is the one thousandth part longer than at the temperature of water freezing. Hence, when great accuracy is required, the temperature of the measure must be noted, that its precise length may be known.

When the sides of the primary triangles are known, they serve as bases by which the situation of objects near them may be determined. In this way, the position of any number of points in a road, or the course of a river, also the situation of towns, country-seats, the boundaries of enclosures, and every feature of a country, may be found, and laid down in a plan or map: and to construct it with accuracy, the principal points should be laid down by their calculated distances from each other, rather than by the measures of the angles formed by the lines joining them, because a point may be more correctly laid down by the intersection of two arcs of circles, than by that of lines which make given angles with a third line.

A small extent of the earth's surface may be regarded as a plane, and lines perpendicular to it as parallel to one another. However, in an extensive survey, such as that of Britain, the curvature of the earth must be taken into account, and then its figure and magnitude enter as elements into all the calculations.

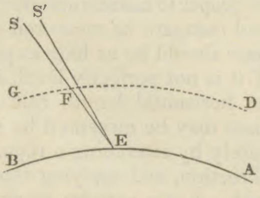
This connection between the figure of the earth and the magnitude and position of lines traced on its surface affords, reversely, the means of determining the former when the latter are known: so that such surveys, besides their immediate object, are applicable to the solution of the still more sublime problem of finding the magnitude and figure of the earth itself.

Of Terrestrial Refraction.

It is a matter of experience, that the rays of light proceeding from the heavenly bodies are bent from their original rectilineal direction in passing through the atmosphere. A ray in its progress may be considered as passing through a very great number of thin *strata* of air, which are denser the nearer they are to the earth; and these, by their action on the particles of light, bend the ray downwards, so that, in fact, its path is a curve line concave towards the earth, and situated in a vertical plane passing through the luminous object and the eye of the observer.

To understand the nature of this effect, let AB (fig. 1) represent a portion of the earth's surface, and DFG the upper boundary of the atmosphere: a succession of particles of light from the sun or a star S, proceed on a straight line, until they arrive at F; afterwards, in their passage through the atmosphere, their path is gradually bent into the curve FE, so that when they reach the eye at E, the object S appears as if it were at S′, in the direction of a straight line which touches the curve at E.

Fig. 1.



This bending of the ray is called *refraction*; it increases the apparent elevation of the heavenly bodies above the horizon, except when they are in the zenith, and in that position there is no refraction.

The rays of light, by which terrestrial objects are rendered visible, are, in their passage through the atmosphere, bent downwards, exactly as those proceeding from the heavenly bodies; so that the apparent elevation of a remote object is always greater than its true elevation. This incurvation is called *terrestrial refraction;* in the case of the heavenly bodies, it is *astronomical* refraction.

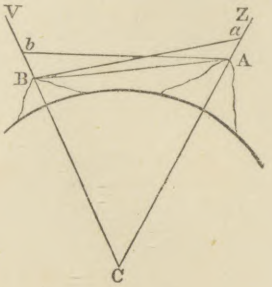
Terrestrial refraction varies with the state of the atmosphere, so that an object appears more elevated at one time than at another: the displacement, however, is always in a vertical plane, but never sensibly in a horizontal direction. How it may be found for any case will appear from the following problem.

Prob. I.

Having given the apparent positions of two remote stations, as seen from each other *at the same instant*, to determine the error produced by refraction.

Let A and B be the stations (fig. 2), and C the earth's centre; draw the lines CA, CB, and produce them towards Z and V, the zeniths of the stations; join AB; then the true zenith distance of B, as seen from A, is the angle ZAB, and the true zenith distance of A, as seen from B, is the angle VBA. These, however, cannot be directly measured, for, by refraction, the point B, as seen from A, appears elevated to the position b; and the point A, as seen from B, is elevated to the position a. The errors, then, produced by refraction are the angles bAB and aBA, and these will be nearly equal, if the angles be observed at the same instant, which may be done by setting two watches to the same time, or making a signal at one station so as to be seen from the other.

Fig. 2.



Put the greater apparent zenith distance $\mathrm{ZA}b = d$,
the lesser $\mathrm{VB}a = d'$,
the refraction $b\mathrm{AB} = a\mathrm{BA} = r$,
the angle C at the earth's centre $= \mathrm{C}$.

Then $\mathrm{ZAB} = \mathrm{ABC} + \mathrm{C}$, and $\mathrm{VBA} = \mathrm{BAC} + \mathrm{C}$ (Geom. 23, 1), therefore $\mathrm{ZAB} + \mathrm{VBA} = \mathrm{ABC} + \mathrm{BAC} + \mathrm{C} + \mathrm{C}$.

But $\mathrm{ABC} + \mathrm{BAC} + \mathrm{C} = 180°$,

therefore $\mathrm{ZAB} + \mathrm{VBA} = 180° + \mathrm{C}$.

Again, $\mathrm{ZAB} = \mathrm{ZA}b + b\mathrm{AB} = d + r$,

$\mathrm{VBA} = \mathrm{VB}a + a\mathrm{BA} = d' + r$,

therefore $\mathrm{ZAB} + \mathrm{VBA} = d + d' + 2r$.

Put the two values of ZAB + VBA equal to each other, and we have

$$d + d' + 2r = 180° + \mathrm{C}, \text{ and } 2r = 180° + \mathrm{C} - (d + d'),$$

$$\text{and } r = 90° + \tfrac{1}{2}\mathrm{C} - \tfrac{1}{2}(d + d).$$

Ex. In the British survey, on Wisp Hill and Cross Fell are two stations in a triangle, which connects the north of England with the borders of Scotland. Their distance is computed at 235,018·6 feet = 44·511 miles, this corresponds on the surface of the earth to an arc of 38′ 33″·7. From Cross Fell, Wisp Hill was seen depressed 30′ 48″ below the horizon, and from the latter place the former was found to have a depression of 2′ 31″. Here we have

$$d = 90°\,30'\,48'', \; d' = 90°\,2'\,31'', \; \mathrm{C} = 38'\,33''{\cdot}7; \text{ hence}$$

$$r = 90° + \tfrac{1}{2}\mathrm{C} - \tfrac{1}{2}(d + d') = 2'\,37''{\cdot}3.$$

In this case the error produced by refraction is nearly $\frac{1}{15}$th of the arc intercepted between the stations. Dr Maskelyne reckoned it to be $\frac{1}{10}$th. Delambre and Legendre, French mathematicians, estimated it, the former at $\frac{1}{14}$th, and the latter at $\frac{1}{11}$th; and Col. Mudge, by numerous and correct observations, found its medium value to be about $\frac{1}{12}$th.

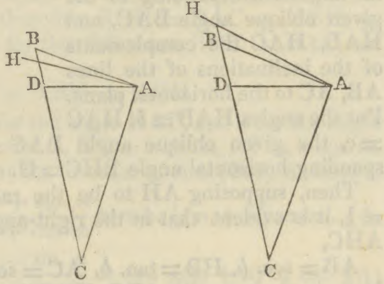
In the examples of the mensuration of heights, the vertical line to be measured has been supposed to stand on the horizontal plane of the station, where the angle of elevation was taken; but in estimating the difference between the heights of two stations which are at a considerable distance from each other, this is not exactly true: in such a case it is necessary to correct the observed vertical angle, on account of the earth's curvature.

PROB. II.

Having given the distance between two stations, and the elevation or depression of the one as seen from the other, to determine the correction to be made in the vertical angle on account of the earth's curvature.

Let A and B be the two stations (fig. 3), and C the earth's centre. Draw the horizontal line AH in the plane of the triangle ABC, then BAH will be the apparent angle of elevation or depression of B, according as it is above or below the horizon of A.

Fig. 3.



Take CD = CA, and join AD; the line BD is the difference between the heights of the stations A and B, and to determine BD, the vertical angle BAD must be known; now this angle differs from the apparent elevation BAH by the angle HAD, therefore HAD is the correction of the vertical angle, depending on the earth's curvature.

In the isosceles triangle ACD, the sum of its angles, that is, 2CAD + C, is equal to two right angles (GEOM. 11 and 24, 1), and therefore CAD + $\frac{1}{2}$C = one right angle; but CAH is a right angle, therefore CAH = CAD + $\frac{1}{2}$C, and taking away the common angle CAD, there remains HAD = $\frac{1}{2}$C. Hence the correction on account of the earth's curvature is *half the arc intercepted between the stations.*

COR. If the station B be above the horizon, as seen from A, the corrected vertical angle will be the sum of its apparent elevation and half C, the angle contained by the verticals passing through the stations; but if B be below the horizon, then it will be the excess of half C above the apparent depression.

Ex. In the British trigonometrical survey, the distance between the stations on Wisp Hill and Cross Fell was found to be 235,018·6 feet, which, reckoning 6094$\frac{1}{2}$ feet to a minute, corresponds to 38′ 33″·7 on the earth's surface. From Wisp Hill, Cross Fell appeared depressed below its horizon 2′ 31″; but, by a corresponding observation at the other station, the error arising from refraction was estimated at 2′ 37″·3. Hence the difference between the heights of the stations is required.

Let A be Wisp Hill, B Cross Fell. The observed depression HAB was 2′ 31″; but as the line AB was elevated 2′ 37″·3 by refraction, the correct value of HAB was 2′ 31″ + 2′ 37″·3 = 5′ 8″·3. This subtracted from HAD = $\frac{1}{2}$C = 19′ 16″·8, leaves 14′ 8″·5 for the vertical angle BAD. And because in the triangle BAD the angle D is almost a right angle, therefore BD will be found by this proportion; rad.: tan. BAD (14′ 8″·5).: AD (235,018·6): BD = 966·8 feet, the height of the station on Cross Fell above that on Wisp Hill.

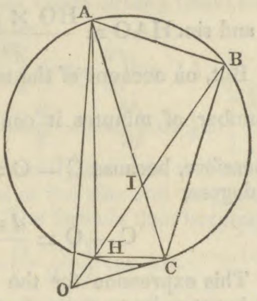
On a survey, it will sometimes happen that the instrument cannot be conveniently placed at the very centre of a station, in order to determine the angles subtended by remote objects: it must then be placed at a point near the station, and the angles taken at that point must be corrected by calculation, so as to reduce them to the centre. How this may be done is shown in the next problem.

PROB. III.

To reduce an angle taken out of a station to the centre of the station.

Let C be the centre of a permanent station (fig. 4), where the angle ACB, subtended by two remote objects A and B, is to be determined; let O be a given point at a little distance, where the instrument is placed, and the angle AOB actually measured; then, having given the distance CO, and the angles COA, COB; also the distances CA, CB, or at least their values nearly, it is required to find the difference between the angles ACB, AOB.

Fig. 4.



Let I be the intersection of AC and BO; and because the angle AIB is the sum of ACB and CBO, also the sum of AOB and CAO (GEOM. 24, 1); therefore

$$\text{ACB} + \text{CBO} = \text{AOB} + \text{CAO},$$

$$\text{and ACB} - \text{AOB} = \text{CAO} - \text{CBO}.$$

Now, in the triangles COA, COB,

$$\text{CA} : \text{CO} :: \sin. \text{COA} : \sin. \text{CAO},$$

$$\text{CB} : \text{CO} :: \sin. \text{COB} : \sin. \text{CBO}.$$

From these proportions, the angles CAO, CBO may be found, and their difference, which is also the difference of the angles ACB, AOB will be known.

It is useful in practice to have a formula that expresses the difference of the angles BCA, BOA in minutes of a degree. For this purpose, put the angles
ACB = C, AOB = O, BOC = v; then COA = O + v;
also put the lines CA = m, CB = n, OC = d;
then the two proportions become
$m : d :: \sin. (\text{O} + v) : \sin. \text{CAO}$; $n : d :: \sin. v : \sin. \text{CBO}$;

hence $\sin. \text{CAO} = \frac{d}{m} \sin. (\text{O} + v)$, $\sin. \text{CBO} = \frac{d}{n} \sin. v$.

But small angles being almost proportional to their sines, it follows that the number of minutes in the angle CAO will be $\frac{\sin. \text{CAO}}{\sin. 1'}$ nearly; and in like manner the number of minutes in the angle CBO will be $\frac{\sin. \text{CBO}}{\sin. 1'}$ nearly; therefore

$$\text{CAO} = \frac{d \sin. (\text{O} + v)}{m \sin. 1'}, \text{CBO} = \frac{d \sin. v}{n \sin. 1'};$$

hence, since CAO − CBO = C − O, we have

$$\text{C} - \text{O} = \frac{d \sin. (\text{O} + v)}{m \sin. 1'} - \frac{d \sin. v}{n \sin. 1'}.$$

This is the correction of the angle O expressed in minutes of a degree; in its application, attention must be paid to the signs of sin. (O + v) and sin. v, agreeably to the rules laid down in *Arithmetic of Sines*, ALGEBRA (225).

A different and more simple expression for the correction of the angle O may be found as follows:

Let a circle be described about the triangle ABC, meeting BO in H, and join CH, AH. Let the angles BCA, BOA, BOC, and the lines CA, CB, CO, be denoted by the same letters as before; and in addition, put the angle BAC = A.

Because

$$C - O\ (= BCA - BOA) = BHA - BOA\ (\text{Geom. } 24,\ 1),$$
$$\text{and } HAO = BHA - BOA,$$
$$\text{therefore } C - O = HAO.$$

In the triangle OHC, sin. CHO or CHB : sin. HCO :: CO : HO; and in the triangle OHA, HA : HO :: sin. HOA : sin. HAO. Remarking now that CHB = CAB = A, and that HCO = CHB — COB = A — v, also that HA and CA = m are nearly equal, these proportions may be expressed thus:

$$\text{sin. A} : \text{sin.}\,(A - v) :: d : HO,$$
$$m : HO :: \text{sin. O} : \text{sin. HAO};$$

$$\text{hence } HO = \frac{d\,\text{sin.}\,(A - v)}{\text{sin. A}},$$

$$\text{and sin. HAO} = \frac{HO \times \text{sin. O}}{m} = \frac{d\,\text{sin.}\,(A - v)\,\text{sin. O}}{m\,\text{sin. A}}.$$

But, on account of the smallness of the angle HAO, the number of minutes it contains will be $\frac{\text{sin. HAO}}{\text{sin. } 1'}$ nearly; therefore, because C — O = HAO, we have, in minutes of a degree,

$$C - O = \frac{d\,\text{sin.}\,(A - v)\,\text{sin. O}}{m\,\text{sin. A sin. } 1'}.$$

This expression for the difference of the angles C and O is not quite so accurate as the former, yet, in practice, it is near enough the truth. It requires that approximate values of the distance AC and the angle BAC be known; the distance d should, however, be accurately determined.

It is obvious that if the instrument were placed at H, in the circumference of a circle passing through A, B, C, the observed angle AHB would then be equal to the angle C at the station. This may be done by moving it along OB until the angle CHB is found to be equal to CAB, and then no correction is wanted.

Ex. In a survey, A, B, C are three stations, and AB = 6196 feet. At A, the angle BAC = 63° 44′, and at O, a point 11·5 feet from the centre of the station C, the angle AOB = 45° 42′; the angle COB = 50° 18′. Hence it is required to find the angle ACB.

The angle ACB will be nearly equal to AOB = 45° 42′, hence CBA = 70° 34′ nearly. In the triangle CAB we have now approximate values of all the angles, and a side AB; hence (by the first case of oblique-angled triangles) BC = 7763, and AC = 8164 feet.

To apply the formulæ for reducing to the centre, we have

$m = 8164$ $O = 45°\ 42'$ $O + v = 96°\ 0'$
$n = 7763$ $v = 50\ \ 18$ $A - v = 13\ \ 26$
$d = 11{\cdot}5$ $A = 63\ \ 44$

to find C — O. The logarithmic calculation by the first formula may stand thus:

d		1·060698	d		1·060698
sin. (O + v)		9·997614	sin. v		9·886152
m	Ar. Comp.	6·088097	n	Ar. Comp.	6·109970
sin. 1′	log.	3·536274	sin. 1′	log.	3·536274
4′·816		0·682683	3′·918		0·593094

Hence C — O = 4′·816 — 3′·918 = 0′·898 = 54″ nearly; this gives C = 45° 42′ 54″.

Calculation by the second formula.

d	....	1·060698
sin. (A — v)	....	9·366075
sin. O	....	9·854727
m	Ar. Comp. log...	6·088097
sin. A	Ar. Comp. log...	0·047331
sin. 1′	Ar. Comp. log...	3·536274
C — O = 0′·898 = 54″		— 1·953202

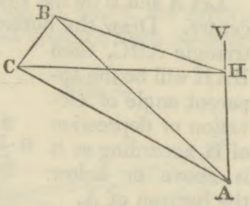
The correction is positive, because the angle A — v is less than 180°, and therefore sin. (A — v) is a positive quantity.

When a theodolite is employed in surveying, the angles are taken at once in a horizontal plane; but when a sextant is used, the angles are measured in the planes of the objects, and if they are oblique, the corresponding horizontal angles are found by calculation.

PROB. IV.

Having given the inclination of each of two lines to the horizon, and the oblique angle they contain, to find the corresponding horizontal angle.

Fig. 5.



Let AB, AC be the straight lines, which contain between them the given oblique angle BAC: in AV, a perpendicular to the horizon, take any point H, and let a horizontal plane pass through H and meet AB, AC in B and C; join HB, HC, BC; then BHC is the horizontal angle corresponding to the given oblique angle BAC, and HAB, HAC the complements of the inclinations of the lines AB, AC to the horizontal plane. Put the angles HAB = b, HAC = c, the given oblique angle BAC = A, and its corresponding horizontal angle BHC = H.

Then, supposing AH to be the radius of a circle, and = 1, it is evident that in the right-angled triangles AHB, AHC,

$$AB = \text{sec. } b,\ HB = \text{tan. } b,\ AC = \text{sec. } c,\ HC = \text{tan. } c.$$

Now, in the triangles ABC, HBC, by TRIGONOMETRY,

$$AB^2 + AC^2 = BC^2 + 2AB \times AC \times \text{cos. A},$$
$$HB^2 + HC^2 = BC^2 + 2HB \times HC \times \text{cos. H};$$

Hence, by subtracting equals from equals, and observing that $AB^2 - HB^2 = AH^2$, and $AC^2 - HC^2 = AH^2$, we have $2AH^2 = 2AB \times AC \times \text{cos. A} - 2HB \times HC \times \text{cos. H}$, that is,

$$1 = \text{sec. } b \text{ sec. } c \text{ cos. A} - \text{tan. } b \text{ tan. } c \text{ cos. H}.$$

From this expression, after substituting $\frac{1}{\text{cos. } b}$ and $\frac{1}{\text{cos. } c}$ for sec. b and sec. c, also $\frac{\text{sin. } b}{\text{cos. } b}$ and $\frac{\text{sin. } c}{\text{cos. } c}$ for tan. b and tan. c, we get

$$\text{sin. } b \text{ sin. } c \text{ cos. H} = \text{cos. A} - \text{cos. } b \text{ cos. } c.$$

Now cos. H = 1 — 2 sin.^{2} $\frac{1}{2}$H (ALGEBRA, 248), hence, by substituting and transposing, we get this other expression,

$$2 \text{ sin. } b \text{ sin. } c \text{ sin.}^2 \tfrac{1}{2}H = \text{cos. } b \text{ cos. } c + \text{sin. } b \text{ sin. } c - \text{cos. A}.$$

Again, cos. b cos. c + sin. b sin. c = cos. (b — c) (239), and cos. (b — c) — cos. A = 2 sin. $\frac{A + (b - c)}{2}$ sin. $\frac{A - (b - c)}{2}$ (240); therefore,

$$2 \text{ sin. } b \text{ sin. } c \text{ sin.}^2 \tfrac{1}{2}H = 2 \text{ sin. } \frac{A + (b - c)}{2} \text{ sin. } \frac{A - (b - c)}{2}.$$

If we put $\frac{A + b + c}{2} = s$, then $\frac{A + (b - c)}{2} = s - c$, $\frac{A - (b - c)}{2} = s - b$, and

$$\text{sin. } b \text{ sin. } c \text{ sin.}^2 \tfrac{1}{2}H = \text{sin. } (s - b) \text{ sin. } (s - c),$$

and hence

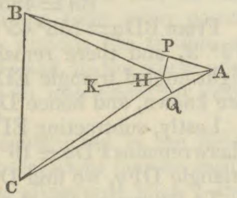
$$\text{sin. } \tfrac{1}{2}H = \sqrt{\frac{\text{sin. } (s - b) \text{ sin. } (s - c)}{\text{sin. } b \text{ sin. } c}}.$$

NOTE. In this formula, the sines are supposed to be computed to a rad. = 1, but in the table of log. sines, the rad. is a number of which the log. is 10; therefore, to adapt the formula to the table, we must divide each sine to rad. = 1 by this number, so that calling the number R, we have

$$\sin.\tfrac{1}{2}\mathrm{H} = \mathrm{R}\sqrt{\frac{\sin.(s-b)\sin.(s-c)}{\sin.b\sin.c}}\ldots\ldots\ldots(1)$$

When the lines which contain the given oblique angle have their inclinations to the horizontal plane less than 2° or 3°, the general solution does not conveniently apply. In this case, instead of seeking the horizontal angle directly, it is better to find its difference from the oblique angle.

Fig. 6.



To investigate a rule, let the horizontal triangle BHC (see last figure) be applied upon the plane of the oblique triangle BAC, so that they may still have a common base BC; join AH, producing it to K, and draw HP, HQ perpendicular to AB, AC. And because BHK = BAH + ABH, and CHK = CAH + ACH, therefore BHC = BAC + ABH + ACH, and putting d for the difference BHC — BAC, we have

$$d = \mathrm{ABH} + \mathrm{ACH}.$$

Put r for AH, m for the angle HAP, and n for the angle HAQ; then HP $= r\sin.m$, HQ $= r\sin.n$, AP $= r\cos.m$, AQ $= r\cos.n$, and, by the formulæ of Art. (246) ALGEBRA,

$$\frac{\mathrm{HP}+\mathrm{HQ}}{\mathrm{AQ}+\mathrm{AP}} = \frac{\sin.m+\sin.n}{\cos.n+\cos.m} = \tan.\tfrac{1}{2}(m+n) = \tan.\tfrac{1}{2}\mathrm{A},$$

$$\frac{\mathrm{HP}-\mathrm{HQ}}{\mathrm{AQ}-\mathrm{AP}} = \frac{\sin.m-\sin.n}{\cos.n-\cos.m} = \cot.\tfrac{1}{2}(m+n) = \cot.\tfrac{1}{2}\mathrm{A};$$

$$\text{therefore } \mathrm{HP}+\mathrm{HQ} = (\mathrm{AQ}+\mathrm{AP})\tan.\tfrac{1}{2}\mathrm{A},$$

$$\mathrm{HP}-\mathrm{HQ} = (\mathrm{AQ}-\mathrm{AP})\cot.\tfrac{1}{2}\mathrm{A};$$

and, by adding and subtracting,

$$\mathrm{HP} = \frac{\mathrm{AQ}+\mathrm{AP}}{2}\tan.\tfrac{1}{2}\mathrm{A} + \frac{\mathrm{AQ}-\mathrm{AP}}{2}\cot.\tfrac{1}{2}\mathrm{A},$$

$$\mathrm{HQ} = \frac{\mathrm{AQ}+\mathrm{AP}}{2}\tan.\tfrac{1}{2}\mathrm{A} - \frac{\mathrm{AQ}-\mathrm{AP}}{2}\cot.\tfrac{1}{2}\mathrm{A}.$$

Supposing b and c to denote the same things as in the general solution, put b' for the difference between b and a right angle, and c' for the difference between c and a right angle, then b' and c' are the inclinations of the sides of the given oblique angle to the horizontal plane.

The lines BA, BH are nearly equal, because the one is the secant and the other the tangent of an angle nearly = 90°; and the same is true of the lines CA, CH; hence the points A and H will be near each other, and the angles ABH, ACH will be small, and BP = BH nearly, also CQ = CH nearly; and since

$$\left.\begin{aligned}\mathrm{BA} &= \sec.b = \operatorname{cosec}.b' = \tfrac{1}{2}\cot.\frac{b'}{2} + \tfrac{1}{2}\tan.\frac{b'}{2}\\ \mathrm{BH} &= \tan.b = \cot.b' = \tfrac{1}{2}\cot.\frac{b'}{2} - \tfrac{1}{2}\tan.\frac{b'}{2}\end{aligned}\right\}\begin{array}{c}\text{ALGEBRA}\\ (249);\end{array}$$

$$\text{therefore, by subtracting, } \mathrm{AP} = \mathrm{BA} - \mathrm{BH} = \tan.\frac{b'}{2}.$$

In like manner it appears that $\mathrm{AQ} = \mathrm{CA} - \mathrm{CQ} = \tan.\frac{c'}{2}$.

These values of AP and AQ being substituted in the values of HP and HQ, we have

$$\mathrm{HP} = \frac{\tan.\frac{c'}{2} + \tan.\frac{b'}{2}}{2}\tan.\tfrac{1}{2}\mathrm{A} + \frac{\tan.\frac{c'}{2} - \tan.\frac{b'}{2}}{2}\cot.\tfrac{1}{2}\mathrm{A},$$

$$\mathrm{HQ} = \frac{\tan.\frac{c'}{2} + \tan.\frac{b'}{2}}{2}\tan.\tfrac{1}{2}\mathrm{A} - \frac{\tan.\frac{c'}{2} - \tan.\frac{b'}{2}}{2}\cot.\tfrac{1}{2}\mathrm{A}.$$

Now, in the triangles HBP, HCQ, because $\mathrm{HB} = \cot.b' = \frac{1}{\tan.b'}$, and $\mathrm{HC} = \cot.c' = \frac{1}{\tan.c'}$, we have

$$\sin.\mathrm{HBP} = \frac{\mathrm{HP}}{\mathrm{HB}} = \mathrm{HP}\times\tan.b';$$

$$\sin.\mathrm{HCQ} = \frac{\mathrm{HQ}}{\mathrm{HC}} = \mathrm{HQ}\times\tan.c;$$

therefore, by adding, and observing that the sum of the sines of the angles HBP, HCQ, is, by reason of their smallness, almost equal to twice the sine of half their sum, that is, to twice the sine of $\tfrac{1}{2}(\mathrm{H}-\mathrm{A}) = \tfrac{1}{2}d$, we have

$$2\sin.\tfrac{1}{2}d = \mathrm{HP}\times\tan.b' + \mathrm{HQ}\times\tan.c'.$$

In this expression, substitute the values already found for HP and HQ, and the result will be

$$2\sin.\tfrac{1}{2}d = \left\{\begin{aligned}&\tfrac{1}{2}(\tan.c'+\tan.b')\left(\tan.\frac{c'}{2}+\tan.\frac{b'}{2}\right)\tan.\tfrac{1}{2}\mathrm{A},\\ &-\tfrac{1}{2}(\tan.c'-\tan.b')\left(\tan.\frac{c'}{2}-\tan.\frac{b'}{2}\right)\cot.\tfrac{1}{2}\mathrm{A}.\end{aligned}\right\}(2)$$

The approximation will be sufficiently accurate, and more simple, if we put the arcs instead of the sine and tangents, to which they are almost equal. The formula then becomes

$$d = \left(\frac{c'+b'}{2}\right)^2\tan.\tfrac{1}{2}\mathrm{A} - \left(\frac{c'-b'}{2}\right)^2\cot.\tfrac{1}{2}\mathrm{A}.$$

In this formula, the arcs or angles d, b', c' are expressed in parts of the radius. If we suppose the same letters to express the number of minutes in each, then, observing that an arc of 1′ = ·00029888, in parts of the radius, we must substitute $d\times{}$·00029888, or, which is the same thing, $\frac{d}{3438}$ instead of d, and similarly, $\frac{b'}{3438}$ and $\frac{c'}{3438}$ instead of b' and c'. This being done, and the quantities $\tan.\tfrac{1}{2}\mathrm{A}$ and $\cot.\tfrac{1}{2}\mathrm{A}$ being divided by R, the radius, for the convenience of logarithmic calculation, we have

$$d = \left\{\left(\frac{c'+b'}{2}\right)^2\frac{\tan.\frac{1}{2}\mathrm{A}}{\mathrm{R}} - \left(\frac{c'-b'}{2}\right)^2\frac{\cot.\frac{1}{2}\mathrm{A}}{\mathrm{R}}\right\}\frac{1}{3438}\ldots\ldots(3)$$

NOTE. We have supposed the angles b', c' to be both elevations. If one be a depression, the formula will still hold true, provided the arc of depression be regarded as a negative quantity. This may be inferred from the position of the lines, also from the rules for the signs of the cosine and sine of an arc (ALGEBRA, 225).

Ex. 1. The angles of elevation of two straight lines, which contain an oblique angle of 64° 10′, are 6° 20′ and 8° 46′: Find the corresponding horizontal angle.

$$\begin{array}{lrrll}
\text{In this case A} = 64^\circ & 10' & & \multicolumn{2}{l}{\text{Log. calcu. by the 1st formula.}}\\
b = 90^\circ - 6^\circ\,20' = 83 & 40 & & \sin.b\ \big\}\ \text{Ar. Co.} & 0{\cdot}002659\\
c = 90\ \ - 8\ \ 46 = 81 & 14 & & \sin.c\ \big\} & 0{\cdot}005104\\
2)\overline{229} & \overline{4} & & &\\
s = \ \ 114 & 32 & & &\\
s-b = \ \ 30 & 52 & & \sin.(s-b) & 9{\cdot}710153\\
s-c = \ \ 33 & 18 & & \sin.(s-c) & 9{\cdot}739590\\
 & & & & 2)\overline{19{\cdot}457506}\\
 & \multicolumn{3}{r}{\sin.\tfrac{1}{2}\mathrm{H}\quad 32^\circ\,22'\,42''} & 9{\cdot}728758
\end{array}$$

The horizontal angle H = 64 45 24, the answer.

As the ar. comp. of two logarithms are added, we ought to reject 20 from the sum, or 10 from half the sum; but the formula requires that 10, the log. of rad., be added to half the sum. As these operations compensate each other, both are here omitted.

Ex. 2. As an example of the second formula, let A = 97° 36′; c', an angle of elevation, = 1° 30′; b', an angle of depression, = 1° 6′: Find the horizontal angle H.

Here $c' = +90'$, $b' = -66'$, $c'+b' = 90' - 66' = 24'$, $c'-b' = 90' + 66' = 156'$. The calculation by logarithms may be thus:

	Log.		Log.
$\left(\frac{c+b}{2}\right)^2$	2·158362	$\left(\frac{c-b}{2}\right)$	3·784190
tan. $\frac{1}{2}$A	10·057777	cot. $\frac{1}{2}$A	9·942223
3438 Ar. Co.	6·463694	3438 Ar. Co.	6·463694
0′·048	— 2·679833	1′·549	0·190107

Here 20 is subtracted from each sum, viz. 10 because of the ar. co. of the log. that is added, and 10 because the rad. is a divisor of each term of the formula. The calculation gives $d = 0'·048 - 1'·549 = -1'·501 = -1'\,30''$, a negative quantity, and the required horizontal angle is 97° 36′ — 1′ 30″ = 97° 34′ 30″.

Scholium. If a station be taken at a known height above a horizontal plane, and the oblique angles subtended by any number of objects be measured, also their depressions, the corresponding horizontal angles may be found by this problem. Their horizontal distances may also be found, and their places laid down in a map of the country.

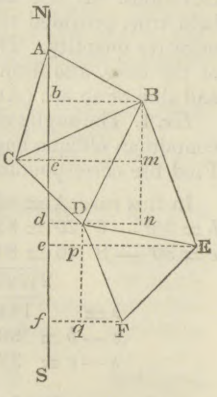
When a tract to be surveyed has been covered with a series of triangles, so as to connect the principal points, and all the angles of each, and a side of one, are known, the sides of all the triangles may be found, and a plan made, by constructing the triangles on the sides of each other; but in a plan constructed by this method, an error in the position of one triangle must necessarily affect the positions of all the others that depend on it.

To avoid this inconvenience, we may determine the position of a side of one of the triangles in respect of a meridian, or line drawn due north and south, by a compass, or more accurately by astronomical observations, and then calculate the distances of all the stations from the meridian, and also the distances from each other reduced to the direction of the meridian: from these, the position of each station may be laid down in the plan independently of the others, and also the direct distance between any two points may be easily found. The manner of proceeding will appear from the following example.

Let A, B, C, D, E, F, be six stations connected by four triangles ABC, BCD, BDE, EDF; the angles are

BAC =	79° 20′	CBD =	39° 20′
ABC =	51 31	BCD =	69 28
ACB =	49 9	BDC =	71 12
sum =	180	sum =	180
DBE =	45° 28′	EDF =	62° 3′
BDE =	72 3	DEF =	52 25
BED =	62 29	DFE =	65 32
sum =	180	sum =	180

Fig. 7.



A side AB of one of the triangles is 4213 yards, and it makes with NS, the meridian, an angle of 62° 52′ at the point A. Find the points in which perpendiculars from the stations cut the meridian, and the length of each perpendicular.

Draw B*b*, C*c*, D*d*, E*e*, F*f* perpendicular to the meridian, and B*n*, D*q*, parallel to it, forming the right-angled triangles AB*b*, BC*m*, BD*n*, ED*p*, FD*q*. Because the angles of the four triangles ABC, BCD, BDE, DEF are given, and also AB, a side of one of them, the five lines AB, BC, BD, DE, DF may be found from AB and each other (by case 1, oblique-angled triangles). Their logarithms will be

AB 3·624591, BD 3·733559, DF 3·578533,
BC 3·738255, DE 3·638690.

In the right-angled triangle AB*b*, the side AB (or its log.) and the angle BA*b* = 62° 52′ are known; hence we find A*b* = 1921·4, B*b* = 3749·3 yards.

If from AB*m* = 117° 8′ (the sup. of BA*b*) the angle ABC = 51° 31′ be taken, there remains CB*m* = 65° 37′. Therefore, in the right-angled triangle CB*m*, the angles and the log. of BC are now known; hence we find B*m* = 2259·6, C*m* = 4985·2.

And if from CB*n* = 65° 37′, CBD = 39° 20′ be subtracted, there remains DB*n* = 26° 17′. Therefore, in the right-angled triangle DB*n*, the angles, and the log. of BD, are known; and hence

B*n* = 4854·7, D*n* = 2397·6.

From BD*q* = 153° 43′ (the sup. of BD*n*) subtract BDE = 72° 3′, and there remains ED*p* = 81° 40′; then, in the right-angled triangle ED*p*, the angles, and the log. of DE, are known, and hence D*p* = 630·7, E*p* = 4306·1.

Lastly, subtracting EDF = 62° 31′ from ED*p* = 81° 40′, there remains FD*q* = 19° 37′; and hence, in the right-angled triangle DF*q*, we find D*q* = 3569·1, F*q* = 1272·1.

To determine the stations, we have now

	Yards.		Yards.
A*b* .... =	1921·4,	B*b* .... =	3749·3,
A*c* = A*b* + B*m* =	4181·0,	C*c* = C*m* — B*b* =	1235·9,
A*d* = A*b* + B*n* =	6776·1,	D*d* = B*b* — D*n* =	1351·7,
A*e* = A*d* + D*p* =	7406·8,	E*e* = D*d* + E*p* =	5657·8,
A*f* = A*d* + D*q* =	10345·2,	F*f* = D*d* + F*q* =	2623·8.

By these numbers the position of each station may be laid down with great accuracy in a plan, independently of the others: also the distance between any two may be readily found; for example,

$$CE = \surd\left\{(Cc + Ee)^2 + (Ae - Ac)^2\right\} \quad (\text{Geom. } 13, 2).$$

Of Surveying with a Compass.

When a tract of country is to be surveyed with expedition, and no great degree of accuracy is required, the compass, notwithstanding its imperfections, is preferable to any other instrument. Even in a correct survey, it may be applied with advantage in filling up the less important parts of a plan.

The principle which renders the compass applicable to surveying is generally known. The instrument should admit of being fixed in a horizontal position on the top of a staff, and it should be furnished with two sights diametrically opposite to each other. The circumference of a circle immediately under or opposite to the point of the needle should be divided into degrees, and it may be numbered both ways, beginning from the extremities of the diameter that passes through the sights; or it may be numbered all one way from 0° to 360°, beginning at a point immediately under one of the sights.

The use of the instrument is to determine the bearings of objects as seen from each other, or the angles which the lines joining them make with the magnetic meridian. Thus, if the perimeter of a polygon is to be surveyed and laid down on paper, the instrument must be placed at one of its angles, so that an object at the next angle may be seen through the two sights. The needle of the compass being then allowed to turn freely on its pivot, it will settle in the magnetic meridian, and point out on the divided circle the number of degrees the line deviates from the north or south, and on which side of the meridian it lies. If this be done at each angle, the positions of all the lines in respect of the magnetic meridians passing through their intersections will be determined. The sides of the polygon may be measured in passing from one angle to another; and then, as the meridians may be supposed parallels, sufficient data will be obtained for constructing a plan of the figure, and verifying the accuracy of the survey; for any angle of the figure will manifestly be equal to the sum or difference of the angles which the lines that contain it make with the meridian passing through their intersection, according as they lie on opposite sides or the same side of that meridian.

All the angles of the figure may therefore be found; and, if they have been accurately observed, their sum, together with four right angles, will make twice as many right angles as the figure has sides (GEOM. 21, 1). If the survey begin and end at the same point, the positions of the beginning and end ought to coincide in the plan.

If the lines which join the objects do not form an enclosed figure, still the manner of proceeding may be the very same; and the positions of many points may be determined by observing their bearings from other points having given positions in the plan, without the trouble of measuring distances on the ground; and, in the whole process, the compass serves merely as an instrument for measuring angles.

In practice, the figure may be constructed in the field, or else a mode of registering the observations may be easily devised, from which a plan may be afterwards made; and it may prevent mistakes, if the bearings of all the objects be reckoned from the north quite round the circle in one direction, either to the right or left. Thus, proceeding to the right, we may consider all lines on the east side of the meridian between due north and due south as making with it angles between 0° and 180°, and all lines on the west side between due south and due north as making angles between 180° and 360°.

It must be recollected that the magnetic does not coincide with the true meridian, and that the angle between them, called the variation of the compass, changes. It varies at different times and in different places (see MAGNETISM). In 1823 it was 27° 48′ at Edinburgh, and 24° 10′ at London: the deviation was westerly.

This mode of surveying was applied by Richard Norwood, an English mathematician of the seventeenth century, to determine the magnitude of the earth. Having found the latitudes of London and York, he travelled from the one place to the other, measuring along the road with a chain, and taking the bearings with a compass. He says, "When I measured not, I paced; and I believe the experiment has come within a scantling of the truth."

In our article MENSURATION, we have explained the principal problems by which heights and distances are determined by trigonometry: these find continual application in surveying. The theory of levelling is a branch of the same subject; this has been discussed in a particular article (see LEVELLING). Maritime surveying requires the solution of this problem: *Three stations being given, and the angles which the lines joining them subtend at a fourth station in their plane; to determine the position of that fourth station.* This is Problem V. in our article MENSURATION OF HEIGHTS AND DISTANCES, and is there resolved in the usual way. Since that was printed, Dr Wallace, emeritus professor of mathematics in the University of Edinburgh, has published a work entitled "Geometrical Theorems and Analytical Formulæ," in which various new formulæ and constructions are given for this and other geodetical problems.

On extensive trigonometrical surveying, see the following works: Delambre, Base du Système Métrique Décimal, 3 vols. 1806–10; Biot et Arago, Recueil d'Observations Géodésiques, &c. 1821; Dalby, Mudge, Colby, &c. Trigonometrical Survey of Britain, 1799–1811; Puissant, Traité de Géodésie, 2 vols. 1819. (R.)

SURVIVORSHIP. See ANNUITIES and MORTALITY.

SUSA, the ancient royal residence of the kings of Persia, built by Darius the son of Hystaspes, according to Pliny, though he perhaps only restored it, being a very ancient city, founded by Tithonus, father of Memnon. Its compass was said by ancient authors to be 120 stadia; but the ruins give us the idea of a still greater extent. They are situated on the east side of the river Kerah, in the latitude of 32°, stretching not less than twelve miles from one extremity to the other. These ruins consist of hillocks of earth and rubbish, covered with broken pieces of brick and coloured tile. One of these hillocks is a mile in circumference, and 100 feet high. Another, though not quite so high, has double the circuit. Large blocks of marble covered with hieroglyphics are frequently discovered by the Arabs. There is a building, apparently modern, called the tomb of Daniel.

SUSA, a province of the department of Turin, in the continental part of the kingdom of Sardinia. It is on the frontier towards France. It is 704 square miles in extent, and forms a large valley with two terminations or horns, through one of which is the road over Mount Genevre to France by the Cottian Alps, and the other passes over Mount Cenis, and so into Savoy; but the latter is by far the preferable road. In the western part of the province lofty rugged rocks and even glaciers are to be seen; but in the west is an alternation of valleys and gentle hills, with a fertile soil watered by the river Dora, which runs to Turin. The district produces abundance of wine, flax, hemp, and silk, but is deficient in corn, and chestnuts are much used as a substitute for grain. There are iron mines and marble quarries worked; and much linen is spun and woven. The province has the title of a marquisate, and contains a city, with sixty-five towns and villages, and about 70,000 inhabitants.

The capital is the city of the same name at the foot of the Alps, on the river Dora, which here receives the Einische. The town is badly fortified, and is rather meanly built. It is the see of a bishop, has a cathedral and two monasteries, with nearly 2000 inhabitants, whose chief occupation is making gloves, and spinning cotton thread. It is a place of great antiquity, and must have been formerly of importance in a military view, from its situation on the only road then known from Gaul into Italy; to defend which it had the castles of Santa Maria and La Brunette, which were destroyed by the French in 1796. Here stands a beautiful triumphal arch in honour of Augustus, which is in good preservation. This place is twenty-three miles from Turin, in longitude 6. 50. 10. E., and latitude 45. 8. N.

SUSEDOON, a town of Hindustan, province of Delhi, situated near the ancient canal of the Sultan Feroz. Long. 76. 30. E. Lat. 29. 20. N.

SUSPENSION, in musical harmony. See MUSIC.

SUSPENSION BRIDGE is such a structure as is hung and stretched across some chasm, water-course, or other space, over which it is designed to form a passage. In Thibet, Peru, and various other remote regions, bridges on this principle, though of an extremely rude and perishable construction, and forming a most unstable and oscillating path, seem to have existed anterior to any thing which is at present known of the history of those countries; but the introduction of suspension bridges into civilized states, at least on a large scale and of a substantial fabric, is of very modern date. The leading features in the structure of the latter sort have hitherto, for the most part, consisted in fixing securely in the two opposite banks, the extremities of strong chains, which, being carried over piers or pillars, reach across the space to be passed, in such a manner that each portion of chain intercepted between two piers is allowed naturally to assume by its weight the figure of the curve thence named the *catenaria*. From these chains, a platform for the roadway is suspended by means of a series of equidistant vertical roads. Some bridges approaching to this description are said to have existed in China for many

Menai Bridge.

ages, though these cannot be expected to bear any close comparison with the productions of more intelligent artists, and especially the famous bridge which Telford constructed across the Menai Straits, to connect the Isle of Anglesea with the coast of Wales, and which at the time of its being completed (1826) was the largest of the kind in the world. The span of the suspended or central arch, between the highest points of the chains on the tops of the piers, and 153 feet above high water in the straits, is 560 feet, and the versed sine or depression in the middle is forty-three feet. Seven stone arches, of $52\frac{1}{2}$ feet span each, make up the rest of the bridge; four of those being next the island, and three on the Welsh coast. But the chains, of which there are sixteen, reach over the whole structure, and, besides, descend sixty feet in sloping pits or shafts, to where they are secured by means of cast-iron frames ingrafted in the rocks; the entire length of each chain being 1714 feet, or almost one third of a mile. The two suspension piers of the middle arch rise fifty-two feet above the roadway, and are surmounted by cast-iron blocks and saddles, moveable upon friction-rollers, for the purpose of allowing the chains which pass over them to move with freedom when expanding or contracting under the vicissitudes of temperature. The suspended platform, elevated 100 feet above high water, is occupied by two carriage-roads, each twelve feet wide, with a footpath of four feet between them. These pass through arches in the suspension piers; and each is separated and strongly railed in by lattice ironwork, both for protection, and also for stiffening the roadway to prevent vibration. Each of the chains is fivefold, being composed of five series of iron bars, in such a manner that there are eighty bars in the cross section of the whole chains. Each bar is nine feet nine inches in length, three inches in breadth, and one in thickness, with six connecting plates at each double joint, eighteen inches long by ten broad, and one thick; the whole being secured by two bolts of fifty-six pounds each. The design of such complexity is, that any part of the chain may with safety be removed at any time for repair, or be replaced by a new one.

Freyburg Bridge.

The Menai Bridge, however, has been greatly surpassed, both in length and height, by a far lighter and much less expensive one, though of great strength, which has since been constructed by M. Challey of Lyon, over the river Sarine, at Freyburg, in Switzerland. This was completed in 1834. The span is 870 feet, and the roadway is elevated 167 feet above the water of the Sarine. The lightness of this bridge is in a great measure owing to its neither being suspended by chains nor solid iron rods, but by four cables of iron wire, each containing about 1200 wires, the united strength of which could support thrice the load they will ever be likely to bear, or three times the weight of two rows of loaded waggons extending over its whole length. It is greatly in favour of these cables that the wires have not been twisted together like so much hair or hemp; for we have no doubt that twisting would have increased the stress in the ratio of radius to the cosine of the obliquity, as it must unavoidably do in ordinary ropes; but each wire just preserves the same direction as the cable itself does, and which, between the piers, is that of a catenarian curve, depressed fifty-five feet at the middle. Two of the cables are placed close together at each side of the bridge; each cable, except where it passes in a flattened shape over friction-rollers on the tops of the piers, has the whole of its wires firmly bound into a cylindrical form, by means of annealed wire wound round them at intervals of two or three feet. They are painted white, both for preservation, and that the least tendency to rust might be detected at once. The cables first enter the banks in a sloping direction, and after passing over friction-rollers, and then descending forty-five feet vertically in shafts cut in the rock, they are finally attached at the bottom to massy blocks of stone, which are securely held down by means of masonry, filling up the shafts in a dovetailed form.

Defects of the catenaria.

But the catenarian form of suspension, however well suited to support a heavy load uniformly distributed over it and at rest, is by no means easily restrained from a readiness which it naturally has to yield, like a fluid, to any change or inequality in the pressure, and consequently to oscillate or undulate when used for a bridge which has to support loads that are not only very unequal, but perpetually shifting their positions on it. To remedy or obviate this defect, various schemes have at different times been proposed. Some of these are merely attempts to stiffen the fabric by means of stays, strongly trussed railings, &c. In other schemes, it has been proposed to abandon the chains and cables altogether, and to use in their stead separate and unyielding suspensions for the different parts of the roadway. Thus in the Annals of Philosophy for January 1818, Mr Loudon has given a design for a bridge to cross the Mersey at Runcorn, in which the suspension is to be effected by a considerable number of straight iron rods, radiating from the tops of the piers, and separately attached to two series of equidistant points ranging along the roadway. Under this arrangement, it is evident that no material sinking of a particular part of the roadway could occur without the rods which supported it giving way altogether, and it were easy to have these as strong as any chains. Nearly the same scheme was afterwards given by Mr Seaward in the Philosophical Magazine for December 1823, and has been still more recently proposed again, with some improvements, by Mr Curtis, at the Liverpool meeting of the British Association, under the title of "an inflexible suspension bridge." At the Newcastle meeting, a scheme was brought forward by Mr Dredge, for what he calls "a mathematical suspension." His paper then read has been printed with some additions in the Mechanics Magazine for October 1838; but instead of any thing mathematical, the terms in which he has expressed himself are so enigmatical, if not paradoxical, that, from an attentive perusal, we have only been able to gather, that by means of a tapering chain, and what he calls "diagonal rods," he professes (though without explaining how) both to lessen the strain greatly, and also to proportion the strength of the several parts so accurately to the stress, as to require a much less quantity of materials than usual. He farther informs us that a bridge constructed at Bath, on these unexplained principles, has answered admirably. There are various other projects for bridges, which our limits will not permit us to specify. (E. E. E.)

Boundaries. Extent. Divisions.

SUSSEX, an English maritime county, bounded on the east by Kent, on the north by that county and Surrey, on the west by Hampshire, and on the south by the British Channel. It is of an oblong shape, being about seventy miles in length from east to west, and nowhere more than twenty-six miles in breadth from north to south. Its area is 1463 square miles, or 936,320 statute acres. It is divided into six portions, provincially called *rapes*, which are again divided into sixty-five hundreds, and contain 313 parishes. The greater part of the county is within the diocese of Chichester; but the deaneries of Pagham and South Malling, and All-Saints in Chichester, form a part of the peculiar of the archbishop of Canterbury.

Population.

The population of this county at the four decennial periods of enumeration amounted, in 1801 to 159,311, in 1811 to 190,083, in 1821 to 233,019, and in 1831 to 272,800.

At the last period the distribution of the inhabitants was,

Occupiers of land employing labourers	3,160
Occupiers not employing labourers	1,330
Labourers employed in agriculture	26,125
Labourers employed in manufactures	109
Labourers in retail trade and handicraft	19,208
Capitalists, bankers, &c	3,094
Labourers not agricultural	8,151

Males at and above twenty years of age	4,094
Male servants	1,531
Female servants	13,366

In the same year the number of families chiefly employed in agriculture amounted to 22,450; of those chiefly employed in trade, manufactures, and handicraft, to 17,439; and of those not comprised in either of the preceding classes, to 12,777. The number of inhabited houses was 45,505, occupied by 52,712 families; of the uninhabited, 1859; and of those building, 620.

The amount of the annual value of the real property of the county, as assessed for the purposes of the property-tax in 1813, was L.915,348.

Towns and villages.

The towns and villages within this county, whose inhabitants exceed 2000, are, with their population in 1831, as follows, viz.

Brighton or Brighthelmstone	40,634	Battle	2,909
		Arundel	2,803
Hastings	10,097	Mayfield	2,738
Lewes	8,592	East Bourne	2,726

Face of the country.

The northern part of the county was formerly a complete forest, and still is very thickly covered with wood, and adorned with the finest oak trees in the kingdom. The soil is generally of so tenacious a clay, and so deep, that, until within a few years, in which roads have been made, and the navigation of the river Arun improved, the timber scarcely paid the expense of carriage to districts where it was needed. A range of chalk-hills, known as the South Downs, runs through the county parallel to the coast, and in some points terminating in the sea. On these, vast flocks of sheep are fed; and in the small valleys intervening, the heaviest crops of wheat and other grain are raised. In the south-west part of the county, there is a tract of arable land of most singular fecundity. On some parts of the coast, where the chalk-hills recede from the shore, there are rich level plains, which feed some of the best oxen that supply the markets of the metropolis.

Landed property.

The size of the estates varies much, but there are no very great proprietors. The farms in the weald or eastern vales are generally small, those on the South Downs as generally large. The average rent of the land, according to the returns under the late property-tax, was 3s. 9d. per acre. More than 100,000 acres are not estimated at above 1s. 6d. per acre, 70,000 acres of down land are estimated at 6s. per acre, and 170,000 of woodland at 8s. per acre. The arable and woodland in the weald, amounting to about 420,000, are estimated at 12s. The marsh land and the arable land in the south-west have been let as high as 50s. per acre. In the weald about one third is arable, one third pasture, and one third wood and waste land. On the south side of the Downs, the arable exceeds the pasture in the proportion of thirty acres to one.

Agriculture.

The agriculture of the county is as various as the differences of the soil. In the stiff lands of the weald, the practice of fallowing is generally prevalent; but to the south of the Downs it is rarely resorted to. The growing of turnips, potatoes, pease, or beans, is commonly found sufficient to prepare the land for corn. Hops are very extensively cultivated in the eastern part of the county; and as nearly the whole manure of the farms is applied to that plant, the crops of wheat and other grain are usually scanty.

Cows.

The cattle of Sussex are celebrated throughout the whole kingdom. The cows are of a deep-red colour, with small heads, and horns thin and transparent, which run out horizontally, and turn up towards the tips. The quality of their milk is not equal to that of some other breeds; hence there are few dairies, and the cattle are chiefly reared for the sake of the meat, which is excellent. As much of the ploughing is performed by oxen, they usually labour in harness three or four years before they are fattened. They are but lightly worked, that their growth may not be impeded; and it is not unusual to see eight and sometimes even ten oxen to a plough. The sheep of Sussex have spread gradually over most parts of the island. The sheep known by the name of South Downs have no horns, and their faces and legs are black or dark coloured. The flesh is surpassed by none in England. Their wool is as fine as that of Herefordshire, and they require less food for their support than sheep of any other breed.

Sheep.

Employments.

There are no manufactures in the county. The making of iron formerly gave employment to many persons in the weald; but the invention of making it with coke instead of charcoal has removed it to those districts where mines of iron and of coal are to be found. The only branch of industry which gives any employment to the population, besides that of agriculture, is the fishery, which, in the summer, especially when the mackerel appear, is extensive. The prosperity of many places on the coast has arisen from the crowds of visitors who frequent them for the pleasures of sea air and bathing. Among those places, Brighton, as the favourite residence of our two last monarchs, as well as of our youthful queen, is the most prominent. Much company is annually collected at Hastings, East Bourne, Rottendean, Worthing, and Bognor.

Rivers.

The rivers of Sussex are all streams of short course. The Lavant and Arun are navigable but a few miles from their mouths. The other rivers are the Adur, which, joining with the Ouse, runs by Lewes to Newhaven; and the Rother, which forms an estuary near Rye. The only canal is one that connects the towns of Petworth and Midhurst with the river Arun.

Antiquities.

There are several remains of Roman camps in different parts of the county; and the Stane Street Road may still be traced between Chichester and Dorking. The Saxon remains are very numerous, among which the most remarkable are Pevensey Castle and Battle Abbey. Arundel Castle is a most splendid modernized edifice, upon the site of the ancient structure of that name. Besides these, Bayham Abbey, Eridge Castle, Bodiham Castle, and the buildings at Winchelsea, are worthy the attention of the antiquary.

Peers and representation.

The titles derived from this county are those of duke of Sussex, earls of Winchelsea, Ashburnham, Chichester, and Sheffield, and Barons Arundel, Gage, and Selsey. For election purposes the county has been formed into two divisions. The eastern election is held at Lewes; and the other polling places are East Grinstead, Battle, and Mayfield. The western election place is Chichester; and the other polling places are Steyning, Petworth, Horsham, and Arundel. By the reform bill the boroughs of Bramber, East Grinstead, and Steyning, have been disfranchised, and Midhurst, Rye, and Arundel, return one member each instead of two. Brighton has been constituted a borough with two members; and Chichester, Hastings, and Lewes, continue, as before, to elect two.

Chief seats.

The most remarkable seats are, the Pavilion at Brighton; Goodwood, the duke of Richmond; Petworth, Colonel Wyndham; Arundel Castle, duke of Norfolk; Sheffield Place, earl of Sheffield; Eridge Castle, earl of Abergavenny; Ashburnham House, earl of Ashburnham; Stanstead, Reverend Lewis Way; Parham, Sir Cecil Bishop; Kidbroke, Lord Colchester; Marisfield Park, Sir John Shelly; Firle, Lord Gage; Stanmer Park, earl of Chichester; Ovingdean, Nathaniel Kemp, Esq.; Eartham, the widow of the Right Honourable William Huskisson; Weshdean House, Lord Selsey.

See Young's Agricultural Survey of Sussex; Russell's

Description of Kent and Sussex; Gilpin's Observations; Pennant's Journey from London to the Isle of Wight; Beauties of England and Wales.

SUTALURY, a town of Bengal, province of Bakergunge, which trades to some extent in grain. Long. 90. 10. E. Lat. 22. 38. N.

SUTCHANA, a town of Hindustan, province of Gujerat, situated to the east of Noanagur, to the chief of which it belongs. An extensive fishery is carried on along this part of the Gulf of Cutch. The pearl-oyster fishery is also carried on here, and is a source of revenue. Lat. not ascertained.

Situation and boundaries.

SUTHERLAND, an extensive county in the north of Scotland, situated between 57° 53′ and 58° 36′ north latitude, and between 3° 39′ and 5° 15′ west longitude from Greenwich; having the sea on the south-east, west, and north, Caithness on the north-east, and Ross-shire on the south. From north to south it extends from 35 to 50 miles, and from west to east from 45 to 50, and contains, according to the latest authorities, 1754 square miles, or 1,112,560 English acres, divided into thirteen parishes, which belong to the synod of Sutherland and Caithness. Of the other divisions, the principal are, Assynt and Edderachylis on the west, and Strathnaver on the east; names recognised by the inhabitants, and which still serve to designate the locality of the natural objects and other circumstances of the country.

Surface.

The coast of Sutherland, like that of the other Highland counties of Scotland, presents a succession of inlets of the sea, and bold promontories, with a number of rocks and islets. The principal arms of the sea are Lochs Assynt, Laxford, and Inchard, on the west; Durness Bay, Loch Eriboll, the Kyle of Tongue, and the bays of Torrisdale and Strathy, on the north; and Loch Fleet in the Frith of Dornoch, on the south-east: and the more remarkable promontories are, Ru Stoir, on the south side of Loch Assynt; Cape Wrath, on the north-west extremity of the county; Far-out Head and Whitten Head, on the north; and Strathy Head, on the north-east. The interior consists of mountains, mosses, lakes, and streams, presenting great variety in form, but almost all having the same general character of being barren, rugged, and dismal, more especially on the western side; and so closely thrown together, that there is no valley of any extent, and seldom a tree or a shrub, to relieve the eye. The Assynt mountains have not even heath to cover their nakedness, except in patches among the rocks near their base. Exceptions to this general character occur on the eastern coast, along the Dornoch Frith, and on the banks of a few of the lakes and rivulets. From its latitude, and exposure to the winds of the German and Northern Ocean, the climate of Sutherland is sharp and cold. On the east coast, however, it is not so severe as to prevent the growth of wheat, which sometimes ripens as early here as in many parts of England.

Rivers.

The principal streams are, Oickel, Fleet, Brora, and Helmsdale, which fall into the Dornoch Frith on the south-east. The tide renders the Oickel navigable by vessels of fifty tons for about twelve miles, and for boats for about eight miles farther; and they have all good salmon fisheries. These rivulets have their sources among the mountains in the centre of the district, and flow south-east. In the same quarter various streams take their rise, and flow in a northerly direction; such as Strathy, the Naver, which gives its name to the tract called Strathnaver, the Dinart, &c., most of them containing salmon. The most considerable lake is Loch Shin, about twenty miles long and one broad, situated on the southern side of the county, through which flows a stream of the same name, which falls into the Oickel. There are several others of considerable extent in different parts, the whole occupying about fifty-three square miles, or nearly 34,000 acres. On the north coast the sea has formed some remarkable caves in the limestone rock, particularly one at Smow, to the east of Balnakeel of Durness, thirty-two yards wide and twenty yards high; and another at Fraisgill, fifty feet high, and twenty feet wide at its entrance, but contracting by degress till its termination, more than half a mile under ground.

Minerals.

The oldest formation of rocks in Sutherland is gneiss, which extends over the whole county, and affords a great diversity of aspect in the stratification. This formation is traversed by granite veins, which abound in various places in the south-east part of the county, as also in the upper part of the parishes of Reay and Edderachylis. The gneiss is also traversed by veins of greenstone and porphyry. Those of the greenstone are found in great abundance in the south-east district of Assynt, and in the country around Scourie in Edderachylis parish. Porphyry veins are of rare occurrence. Mica-slate is developed to a considerable extent in two parts of the county; in that portion of the district of Moin which stretches southwards, and constitutes the whole of the mountains of Ben-Hope, Ben-Hee, and Meal-Rynies; and that part of the county between Loch Fleet and Bonar Bridge. Granite fields prevail in the lower part of the parish of Reay, and in the parishes of Loth and Rogart. Syenite is to be met with in several places. It is most abundant in the mountain of Ben-Laoghal, and that considerable tract of hilly country which intervenes between the head of Loch Fleet and Lairg, at the foot of Loch Shin. The quartz series of rocks occurs principally in greater or less fields in the west part of the county, from Loch Eriboll on the north, to Loch Vattie on the south. This series is connected with sandstone and limestone. The latter is divided into four great fields connected with each other, and running in the same direction as the quartz. There is also a portion of nearly six miles in length at Durness, between Loch Eriboll and Cape Wrath. Red stone and conglomerate are extensively displayed on the east side, and at several points on the north coast and the interior. The oolite series of rocks, consisting of white sandstone, sandstone flag, slate-clay, limestone, and coal, forms the coast between Golspie and the Ord of Caithness, and has a breadth at the river Brora of three miles. At Brora, coal occurs at several points, but it has been found not to be worth the working. Calcareous sinter and bog iron ore are the only chemical alluvial deposits to be found in the county.

Valuation and rental.

This county, which is valued in the cess-books at L.26,193. 9s. 7d. Scots, is almost entirely the property of the duke of Sutherland. In 1812 the gross rental of the lands and houses, as returned under the property-tax act, was L.28,458. 8s. 4d. including about L.1700 as the rent of the salmon and other fisheries. Since that period, the great and extensive improvements effected by the spirited proprietors must have augmented the rental in a corresponding degree. More than half the valuation is held under entail. The principal seats are, Dunrobin Castle, duke of Sutherland, on the coast of the Dornoch Frith, in the parish of Golspie; Skibo, Dempster, on an inlet of the same frith, near the south-eastern corner of the county; and Tongue Castle, on the Kyle of Tongue, on the north coast. Most of the other proprietors have good modern houses, all of which are situated near the coast. In no part of Britain has a greater change been effected in so short a period as in Sutherland, and this chiefly by the spirit and liberality of its greatest proprietor, the duke of Sutherland. Within these twenty or thirty years, roads, bridges, harbours, and villages, have been constructed wherever they seemed to be required; and both the natural and moral obstructions to the improvement of this extensive territory have, as far as it appears practicable, been in a great measure overcome. Before the beginning of the present century, Sutherland was almost in a state of nature, excluded from the benefits of that civilization which had spread over

Seats.

Improvements.

the rest of Britain; and this exclusion was principally owing to the want of roads and other means of communication.

During the last twenty years the greatest changes have taken place. "Before that period, the injurious system of sub-letting prevailed, and both the knowledge and the practice of farming were exceedingly defective. The place of Dunrobin excepted, there was neither draining, trenching, nor fallow, and very little green crop, besides potatoes and a little pease. There were few fences, and these few bad. The plough, which was rudely constructed, had no part of it iron but the coulter, the sock, and the hook at the end of the beam. Four country garrans, or highland ponies, were yoked to the plough abreast, and the driver walked in front of them backwards. There were few wheeled vehicles that deserved the name. Corn, fuel, &c. were carried in a kind of frame called crubags, fastened on horseback to a wooden saddle, that rested on a straw-mat. The public road was the only one, and that itself indifferent. The dwellings of the subtenants were wooden frames, thatched with turf; and of these, one end accommodated cattle, horses, and sometimes pigs. One end also of the turf-coverings of these huts, saturated as it was with soot, was annually stript off and converted into manure. With such dwellings the dress of their tenants corresponded. The state of things is now very different. Farming is brought to the highest degree of excellence that industry, skill, and expense, can bring it. Nor is it too much to say, that the system of farming at present followed in the county does not fall short of the best modes of farming in any part of the kingdom. The farmers have very good houses, with two public rooms; and they have their wheeled carriages for personal and family use. Sub-letting is abolished. The small tenants or cottars live in decent cottages, built with stone and lime, or clay, with glass windows; and their fare is correspondingly better; and the tradesmen and ploughmen wear good clothes. In no county of Scotland was there ever, in so short a time, the same length of road made, as there has been within the last twenty years in the county of Sutherland. In former times the internal communication was by mere paths or tracks, and many parts of it were all but inaccessible. Now, several hundred miles of good road, unchecked by tolls, intersect the county in every direction; and there is free and easy access to every part of it. These roads were made, partly by the parliamentary commissioners and the county, but chiefly at the expense of the noble proprietors, and under the able management of James Loch, Esq. M.P. their commissioner."[1]

Sutherland is eminently adapted by nature for sheep-grazing; and the plans of converting it into extensive sheep-walks, which have been for some years carrying into execution, have greatly augmented the revenue of the proprietors, and added to the commercial wealth of the nation; but they have doubtless been attended with much suffering to the small tenants whom it was necessary to dispossess. The people who had been removed from the interior in 1818 and 1819, when these great changes took place, are densely settled along the sea-coast; in some instances about thirty cottagers occupying the land formerly in the possession of twelve. They have likewise been obliged to make a violent change in their occupations and habits: instead of tending flocks, and following other rural occupations, they have been forced to encounter the hardships and dangers of the sea, and occupy themselves with the fisheries; and many families have preferred emigration from their native country, to engaging in occupations so entirely foreign to their previous habits.

Agriculture.

The ordinary system of husbandry adopted is the five-course shift rotation of crops; and trenching and draining have been executed to a great extent. The rent of arable land is from 20s. to 30s. per acre. The corn-farms are generally of such an extent as yield from L.50 to L.200 of annual rent; few exceed L.300. The average rate of grazing is L.1. 10s. per ox or cow grazed, and 2s. per sheep. The leases of farms are generally for nineteen years; but the cottagers on the coast are almost always tenants at will, which is evidently a bar to the improvement of their cots. But the greater part of the county is laid out in extensive sheep-farms, yielding about L.500 of yearly rent each. The Cheviot or white-faced breed of sheep is that which is generally kept. The Dunrobin breed of cattle, originally from Argyleshire, is excellent. Some Ayrshire cows are kept for dairy use. On some farms the breed of Galloway black-polled cattle, and highland black cattle, are chiefly reared. Goats were once a part of the stock of the farmers, but they have now nearly disappeared.

Manufactures.

Until the recent establishments of the duke of Sutherland, there was no manufacture in this county, if we except that of kelp, of which the quantity used to be 250 tons. A cotton-mill had been erected at Spinningdale, on a branch of the Dornoch Frith, by a Glasgow company; but the building having been burnt down in 1806, the undertaking was abandoned.

Fisheries.

A good many boats are employed in the fisheries on the west and north coast for cod, ling, haddock, and herring; and lobsters and mussels are found in considerable quantities. At Helmsdale, on the east coast, many of those small tenants who were removed by the introduction of sheep-farming, have also embarked in the fisheries with considerable success; and large sums have been expended within these few years by the noble proprietor of the Sutherland estate in erecting the necessary buildings.

Commerce.

The principal exports are sheep, wool, cattle, horses, salmon, and cod. Their butter and cheese are nearly all consumed at home; and besides the usual imports of cloths, groceries, &c., they require some corn, chiefly oatmeal, especially on the west and north sides of the county, where they have very little corn-land.

Dornoch, a royal borough, situated on the south-eastern extremity, on the frith of that name, is the only town, and contains little more than 500 inhabitants. Golspie, Helmsdale, and Brora, are the principal villages. With these exceptions, the inhabitants are scattered along the coast, and in some of the principal straths, passing much of their time in idleness; a healthy, robust, and simple, though not ill-informed race, who have contributed largely to the public service. For the last half century, the Sutherland family have raised among them, at the commencement of every war, a corps of a thousand men, well known by the name of the Sutherland Fencibles; but this military spirit, founded in attachment to their chiefs, has now become much weaker than formerly.

Schools.

The schools in the county are the parish schools, and those of the Society for propagating Christian Knowledge and the Gaelic School Society. According to the last parliamentary returns, there was neither printer nor bookseller in the whole county; a circumstance indicating either great poverty or little literary taste among the inhabitants. Sutherland is distinguished from every other county in the kingdom in being undisturbed by religious dissent; there is not a single dissenting place of worship within its limits. Savings banks have been established in some of the parishes. The only prison in the county is at Dornoch. The number of prisoners during the year 1833 was twenty, of whom six were committed for smuggling, and ten for assaults.

Antiquities.

In various districts along the coast, there are some remains of antiquity. The most interesting are two circular buildings, called Dun Dornadil, or Dornadilla's Tower, and

---

[1] Statistical Account of Scotland.

Antiquities.

Castle Coll, both reared of large stones, nicely fitted, but without cement, and of which considerable portions are still entire, after the lapse of probably 1000 years. Castle Coll, which is situated on the east side of the county, on a stream that falls into the Brora, has an exterior circumference of fifty-four yards, with walls four yards and a half thick at the base, inclining inwards nine inches in every three feet in height; and two small apartments on each side of the door-way, as if intended for guard-rooms. The highest part of the wall is now only eleven feet high, but old people remember it twice that height. Dun Dornadil is in the parish of Durness, on the northern side of the county. It is a building of the same character with the former, but still more dilapidated, and is celebrated in the ancient Gaelic ballads as a place of renown at a very early period. The ruins of Dornoch cathedral still display the original grandeur of that edifice, which is said to have been built in the eleventh century, and repaired and enlarged in the thirteenth. Circular cairns with subterraneous passages, tumuli, and some small forts, may yet be traced in various situations along the coast.

Representation.

The county sends one member to parliament; and the town of Dornoch joins with Cromarty, Dingwall, Tain, Wick, and Kirkwall, in electing one for the Scotish burghs.

Population.

The population, according to the census of 1801, was 23,117, in 1811 it amounted to 23,629, in 1821 to 23,840, and in 1831 to 25,518, of which 12,090 were males, and 13,428 were females. The families employed in agriculture were 3567, in trade and manufactures 409, in all other occupations 1029.

New Statistical Account of Scotland; Henderson's General View of the County of Sutherland; Loch's Account of the Improvements of the Marquis of Stafford in Sutherland; and Cunningham's Essay on the Geology of the County, in Quarterly Journal of Agriculture, No. xlvi.

SUTLER, one who follows the army, and furnishes the troops with provision. Sutlers pitch their tents or build their huts in the rear of each regiment, and about headquarters.

SUTTON-COLDFIELD, a town in the hundred of Hemlingford and county of Warwick, 112 miles from London. It is situated on a bleak hill in a very extensive parish. It has a good church, with a high square tower. The town is neat, and contains many comfortable residences. There is a market on Wednesday, and several fairs. The inhabitants, who are chiefly employed in the manufacture of articles connected with the Birmingham trade, amounted in 1821 to 3466, and in 1831 to 3684.

SUTULEGE, a celebrated river of Hindustan, and the easternmost of those five rivers which are called the Punjab. It has its rise in the lofty ridge of the Himalaya Mountains, and flows in a southerly direction, bounding to the east the country of Lahore, where it enters Hindustan at Bellaspoor. The stream is 100 yards wide when the waters are at the lowest. About the middle of its course it is joined by the Beyah or Hyphasis, in the latitude of 30. N., after which the united stream takes the name of Kirah. It falls into the Indus near the 29th degree, about eighty miles below Moultan. It is navigable 200 miles above its conflux with the Indus. The length of its course, including its windings, may be 600 miles.

SWAFFHAM, a town of the hundred of South Greenhoe, in the county of Norfolk, ninety-three miles from London. It is well built, in a pleasant and healthful district. The church is of the cathedral form, with an elegant turret and steeple. It is not a place of much trade, but has a good market on Saturday. In the market is a handsome cross erected at the expense of the earl of Orford. The number of inhabitants amounted in 1811 to 2350, in 1821 to 2836, and in 1831 to 3285.

SWALLY, a seaport of Hindustan, province of Gujerat, situated at the mouth of the Taptee river; twenty miles west by south of Surat, of which it may be considered as the port. Long. 72. 50. E. Lat. 21. 5. E.

SWAMMERDAM, JOHN, a celebrated natural philosopher, was the son of John James Swammerdam, an apothecary and naturalist of Amsterdam, and was born in 1637. His father intended him for the church, and with this view had him instructed in Latin and Greek; but thinking himself unequal to so serious a vocation, he prevailed with his father to consent to his applying himself to physic. As he was kept at home till he should be properly qualified to engage in that study, he was frequently employed in cleaning his father's curiosities, and putting every thing in its proper place. This inspired him with an early taste for natural history; so that, not content with the survey of the curiosities which his father had purchased, he soon began to make a collection of his own, which he compared with the accounts given of them by the best writers. When grown up, he seriously attended to his anatomical and medical studies; yet spent part of the day and the night in discovering, catching, and examining the flying insects proper to those times, not only in the province of Holland, but in those of Guelderland and Utrecht. Thus initiated in natural history, he went to the university of Leyden in 1651; and in 1653 was admitted a candidate of physic in that university. His attention being now engaged by anatomy, he began to consider how the parts of the body, prepared by dissection, could be preserved, and kept in constant order for anatomical demonstration; and here he succeeded as he had done before in his nice contrivances for dissecting and managing the minutest insects. He afterwards made a journey into France, where he spent some time at Saumur, and where he became acquainted with several learned men. In 1667 he returned to Leyden, and took the degree of M.D. The next year the grand duke of Tuscany being in Holland in order to see the curiosities of the country, came to view those of the father and the son; and on this occasion Swammerdam made some anatomical dissections of insects in the presence of that prince, who was struck with admiration at his great skill in managing them, especially at his proving that the future butterfly lay with all its parts neatly folded up in a caterpillar, by actually removing the integuments that covered the former, and extricating and exhibiting all its parts, however minute, with incredible ingenuity, by means of instruments of inconceivable fineness. On this occasion the duke offered him 12,000 florins for his share of the collection, on condition of his removing them himself into Tuscany, and coming to live at the court of Florence; but Swammerdam, who hated a court life, declined his highness's proposal. In 1663, he published a General History of Insects. About this time, his father began to take offence at his inconsiderately neglecting the practice of physic, which might have supported him in affluence; and would neither supply him with money nor clothes. This reduced him to some difficulties. In 1675 he published his History of the Ephemeras; and his father dying the same year, left him a fortune sufficient for his support; but he did not long survive him, for he died in 1682. Gaubins gave a translation of all his works from the orginal Dutch into Latin, from which they were translated into English, and published in folio, in 1758. Boerhaave wrote his life.

SWAN ISLES, a cluster of small rocky islets, which lie between the north coast of Van Diemen's Land and the south of New Holland. They are uninhabited.

SWANAGE, a town of the hundred of Rowbarrow, in the county of Dorset, on the isle of Purbeck, 127 miles from London. It stands on the sea-shore. A large quantity of stone is shipped from this place for London. The population amounted in 1811 to 1483, in 1821 to 1607, and in 1831 to 1734.

SWANPAN, or **Chinese Abacus**, an instrument for performing arithmetical operations. See Abacus.

SWANSEA, a seaport town of South Wales, in the county of Glamorgan, 206 miles from London. It stands at the mouth of the river Tawy, which serves as its haven. It is a tidal harbour, and can only be entered with the flood-tides, but it has a good dry dock. The town is in a semicircular form, on a rising ground, and has a good appearance. The chief street is wide and long, and contains some very handsome houses of private persons, but scarcely a public building worthy of notice. The shipping that arrives and departs is numerous. The copper ore raised in Cornwall is brought to this town to be smelted in its vicinity. A vast quantity of coal is raised in the neighbourhood, part of which is used in the several manufactories; but a large portion is also exported to Cornwall, Devon, and Somerset. There are establishments for making pottery-ware, tin, cast and wrought iron, and beer. Swansea has of late become a much-frequented bathing place, and has been supplied with all the institutions usually found in similar towns. It is a borough, and for municipal purposes is divided into three wards, and is governed by a portreeve, six aldermen, and seventeen councillors. Jointly with Aberavon, Kenfig, Loughor, and Neath, it returns one member to the House of Commons. It has several fine gentlemen's seats near it. The market is on Wednesday, but the town is well supplied with provisions daily. The inhabitants amounted in 1821 to 10,007, and in 1831 to 13,256.

SWEDEN.

Early history uncertain.

The early history of Sweden is not less involved in fable than that of most other nations. Some historians have pretended to exhibit regular catalogues of the princes who reigned in Sweden in very early times; but they differ so much from each other, that no credit can be given to them. All indeed agree that ancient Scandinavia was first governed by judges elected for a certain time by the voice of the people. Among these temporary princes the country was divided, until, in the year of the world 2054 according to some, or 1951 according to others, Eric, or, if we believe Pufendorf, Sueno, was raised to the supreme power, with the prerogatives of all the temporary magistrates united in his person during his lifetime, or so long as his administration should be satisfactory to the people.

Albert of Mecklenburg declared king. A.D. 1366.

War with Denmark and Norway.

Is defeated and taken prisoner by Margaret of Norway.

From this very early period till the year 1366 of the Christian era, the histories of Sweden present us with nothing but what is common to all nations in their early periods, the endless combats of barbarians, tending to no other purpose than the effusion of blood. At length, however, Albert of Mecklenburg, having concluded a peace between Sweden and Denmark, which had been at violent war for some time before, was proclaimed king of Sweden. The peace was of short duration, being broken in 1368; and Albert then entered into a league, offensive and defensive, with the earl of Holstein, the Jutland nobility, the dukes of Sleswick, Mecklenburg, and the Hanse Towns, against the kings of Denmark and Norway. At that time he proved very successful against Waldemar king of Denmark, driving him entirely out of his dominions; but he himself was defeated by the king of Norway, who laid siege to his capital. A new treaty was soon afterwards concluded, by which Albert was allowed to enjoy the crown of Sweden in peace. Having, however, formed a design of rendering himself absolute, he so displeased his subjects that Margaret of Norway was proclaimed queen of Sweden by the malecontents. A war immediately ensued, in which Albert was defeated and taken prisoner; but as the princes of Mecklenburg, the earls of Holstein, and the Hanse Towns, entered into a league in his favour, the war raged with more fury than ever.

Set at liberty. A. D. 1394.

The contending parties were at length reconciled. Albert was set at liberty, on condition that he should in three years resign to Margaret all pretensions to the city of Stockholm; and the Hanse Towns engaged to pay the sum of 60,000 marks of silver if Albert should break that treaty. Eric, the son of Albert, died not long afterwards; and having no other child, he did not think it worth his while to contend for the kingdom of Sweden: he therefore acquiesced in the pretensions of Margaret, and passed the remainder of his days at Mecklenburg.

Margaret is succeeded by Eric, a cruel tyrant. A. D. 1415.

Margaret died in 1415, and was succeeded by Eric of Pomerania. This prince's reign was cruel and oppressive. His misdeeds produced a revolt; and Charles Canutson, grand mareschal of Sweden and governor of Finland, having joined the malecontents, was declared commander-in-chief of their army. Eric was now formally deposed, and Canutson was chosen regent; but beginning to oppress the people, and aspiring openly to the crown, the Swedes and Danes revolted. This event was followed by a revolution; and Christopher, duke of Bavaria, nephew to Eric, was chosen king of Denmark, Sweden, and Norway, in 1442.

Charles Canutson. A. D. 1448.

On the accession of this prince, complaints against Canutson were presented from all quarters; but through the interest of his friends he escaped punishment; and in 1448, Christopher having died, after a tyrannical reign of about five years, he was raised to the throne to which he had so long aspired. The kingdoms of Denmark and Norway however refused allegiance to him, and a war immediately ensued. In 1454 peace was concluded, and Denmark for the present freed from the Swedish yoke. Nor did Canutson long enjoy the crown of Sweden. Having quarrelled with the magistrates and the archbishop of Upsala, the latter formed so strong a party that the king could not resist him. Canutson died in 1470, after a long and turbulent reign.

A. D. 1520.

Christiern king of Denmark invades Sweden, but is defeated and driven out.

He treacherously carries off six hostages, of whom Gustavus Ericson is one. A. D. 1519.

The affairs of Sweden continued to be involved in the utmost confusion till the year 1520, when a great revolution was effected by Gustavus Ericson, a nobleman of the first rank, who restored the kingdom to its liberty, and laid the foundation of its future grandeur. In 1518, Christiern king of Denmark had invaded Sweden, with a design to subdue the whole country; but being defeated with great loss by young Steen Sture, at that time regent, he set sail for Denmark. Meeting with contrary winds, he made several descents on the Swedish coast, which he ravaged with all the fury of an incensed barbarian. The inhabitants bravely defended themselves, and Christiern was reduced to the utmost distress; one half of his forces having perished with hunger, and the rest being in the most imminent danger by the approach of a rigorous winter. He then thought of a stratagem, which had almost proved fatal to the regent; for having invited him to a conference, at which he designed either to assassinate or take him prisoner, Sture was about to comply, when the senate, who suspected the plot, interposed to prevent him. Christiern then offered to proceed in person to Stockholm in order to confer with Sture, on condition that six hostages should be sent in his place. They were accordingly sent; but the wind happening then to prove favourable, he set sail for Denmark with the hostages, of whom Gustavus Ericson was one. Next year he returned, and having drawn Sture into an ambush, the regent received a wound, of which he died some time after. The kingdom being thus left without a head, matters soon came to the most desperate crisis. The army disbanded itself;

Is chosen king, and proves a most bloody tyrant.

Massacres the nobility.

and the senate, instead of taking proper measures to oppose the enemy, spent their time in idle debates. Christiern in the mean time advanced into the heart of the kingdom, destroying every thing with fire and sword; but on his arrival at Stragnez, he granted a suspension of arms, on condition that they would elect him king. To this condition they submitted, and Christiern proved one of the most bloody tyrants that ever sat on the throne of any kingdom. Immediately after his coronation, he gave grand entertainments for three days; during which time he projected the diabolical design of extirpating at once all the Swedish nobility, and thus for ever preventing the people from revolting, by depriving them of their proper leaders. As the tyrant had signed articles, by which he promised indemnity to all who had borne arms against him, it became necessary to invent some cause of offence against those whom he intended to destroy. To accomplish his purpose, Gustavus Trolle, formerly archbishop of Upsala, but who had been degraded from that dignity, in an oration before his majesty lamented the demolition of Stecka, his place of residence, and the losses sustained by the see of Upsala, amounting to a very large sum of money. He then proceeded in a bitter accusation against the widow and the son-in-law of Sture, the late regent, comprehending in the same accusation about fifteen of the principal nobility, the whole senate, and the burghers of Stockholm. In consequence of this, about sixty of the principal nobility and people of first rank in Sweden were hanged as traitors. Innumerable other cruelties were committed, part of which are owned by the Danish historians, and the whole are minutely related by those of Sweden. At last he departed for Denmark, ordering gibbets to be erected, and causing the peasants to be hanged on them for the slightest offences.

Adventures of Gustavus Vasa or Ericson.

He escapes from Denmark.

Arrives at Lübeck.

This monstrous cruelty, instead of securing him on the throne, exasperated the whole nation against him. It has already been mentioned, that Gustavus Ericson, or, as he is commonly called, *Gustavus Vasa*, was among the number of the hostages whom Christiern had perfidiously carried to Denmark in 1519. Large promises had been made in order to reconcile him to Christiern, and all means had been employed, but in vain. Secret orders were given to strangle him in prison; but the officer to whom the assassination was committed remonstrated to the king about the consequences of it, and prevailed on him to change the sentence of death into close confinement in the castle of Copenhagen. Some of the hostages perished in consequence of the rigorous treatment to which they were subjected; but Gustavus withstood all hardships. At last one Banner, a Danish nobleman, prevailed on the king to place him in his hands, in order to try whether or not he could prevail on him to change his sentiments. The king however told Banner that he must pay 6000 crowns if the prisoner should make his escape. Banner generously consented; and having brought the noble prisoner to his fortress of Calo in Jutland, soon allowed him all the liberty he could desire, and otherwise heaped favours on him. All this however could not extinguish his remembrance of the cruelties of Christiern, and his desire of being serviceable to his country. He therefore determined to make his escape; and the liberty which he enjoyed soon enabled him to accomplish his design. Having one day mounted his horse, under pretence of hunting as usual in the forest, when he got to a proper distance he changed his dress to the habit of a peasant, and quitting his horse, travelled for two days on foot through by-paths, and over wilds almost impassable, arriving on the third at Flensburg. Here no one was admitted without a passport; and Gustavus dreaded presenting himself to the governor or the officer on guard, for fear of being discovered. He hired himself to a cattle-merchant, and in this disguise escaped out of the Danish territories, and arrived at Lübeck.

Attempts in vain to draw the regency of Lübeck over to his side.

He arrives at Calmar, but meets with an unfavourable reception.

Banner was no sooner acquainted with his escape, than he set out after him with the utmost diligence, found him at Lübeck, and reproached him with great warmth as ungrateful and treacherous; but he was soon appeased by the arguments urged by Gustavus, and especially by a promise of indemnifying him in the loss of his ransom. On this Banner returned home, and pretended that he could not find his prisoner. Christiern was enraged at his escape, apprehending that he might reverse all his designs in Sweden; and gave orders to Otho his general to make the strictest search, and leave no means untried to arrest him. Gustavus applied to the regency for a ship to convey him to Sweden, where he hoped he should be able to form a party against the Danes. He likewise endeavoured to draw the regency of Lübeck into his measures; and reasoned with so much zeal and ability, that Nicholas Gemins, first consul, was entirely gained; but the regency could never be prevailed upon to declare for a party without friends, arms, money, or credit. Before his departure, however, the consul gave him assurances, that if he could raise a force sufficient to make head against the enemy in the field, he might depend on the services of the republic, and that the regency would immediately declare for him. Gustavus desired to be landed at Stockholm; but the captain of the ship, either having secret orders to the contrary, or business elsewhere, steered a different course, and put him on shore near Calmar, a city then garrisoned by the troops of Christiana, widow of the regent. In fact, the governor held this place for his own purposes, and only waited to make the best terms he could with the Danes. When Gustavus arrived, he made himself known to him and the principal officers of the garrison, who were mostly Germans, and his fellow-soldiers in the late administrator's army; but the mercenary band, seeing him without troops and without attendants, regarded him as a desperate person devoted to destruction, refused to embrace his proposals, and even threatened to kill or betray him if he did not instantly quit the city.

His friends refuse to assist him.

Disappointed in his expectations, Gustavus departed; and his arrival being now publicly known, he was again forced to have recourse to his peasant's disguise to conceal him from the Danish emissaries dispersed over the country to search for him. In a waggon loaded with hay, he passed through the Danish army, and at last repaired to an old family castle in Sudermania. Hence he wrote to his friends, intimating his return to Sweden, and beseeching them to assemble all their forces in order to break through the enemy's army into Stockholm, at that time besieged; but they refused to embark in so hazardous and desperate an attempt.

Applies in vain to the peasants.

Gustavus next applied himself to the peasants; but they answered that they enjoyed salt and herrings under the government of the king of Denmark; and that any attempts to bring about a revolution would be attended with certain ruin, without the prospect of bettering their condition; for peasants they were, and peasants they should remain, whoever was king. At length, after several attempts to throw himself into Stockholm, after that city was surrendered to the king, after the horrid massacre of the senate, and after running a thousand dangers, and undergoing hardships and fatigues scarcely to be supported by human nature, he formed the resolution of trying the courage and affection of the Dalecarlians. While he was in the deepest obscurity, and plunged in almost insurmountable adversity, he never relinquished his designs nor his hopes. The news of the massacre had, however, nearly sunk him into despondency, as by it he lost all his friends, relations, and connections, and indeed almost every prospect of safety to himself, or deliverance to his country. This suggested the thought of going to Dalecarlia, where he might live with more security in the high mountains and thick woods of that country, if he should fail in the attempt of exciting the inhabitants to revolt.

Arrives in Dalecarlia, is robbed by his guide, and obliged to work in the mines.

Is discovered and relieved.

Attended by a peasant, to whom he was known, he travelled in disguise through Sudermania, Nericia, and Westermania, and, after a laborious and painful journey, arrived in the mountains of Dalecarlia. Scarcely had he finished his journey, when he found himself deserted by his companion and guide, who carried off with him all the money which he had provided for his subsistence. Thus forlorn and destitute, he entered among the miners, without relinquishing his hopes of one day ascending the throne of Sweden. His only object for the present was to live concealed, and gain a maintenance, till fortune should effect something in his favour; nor was it long before this happened. A woman in the mines perceived, under the habit of a peasant, that the collar of his shirt was embroidered. This circumstance excited curiosity; and the graces of his person and conversation, which had something in them to attract the notice of the meanest of the vulgar, afforded room for suspicion that he was some person of quality in disguise, forced by the tyranny of the government to seek shelter in those remote regions. The story came to the ears of a neighbouring gentleman, who immediately went to the mines to offer his protection to the unfortunate stranger; and was astonished on recognising the features of Gustavus, to whom he had been known at the university of Upsala. Touched with compassion at the deplorable situation of so distinguished a nobleman, he could scarcely refrain from tears. At night he sent for the illustrious wanderer, made him an offer of his house, and gave him the strongest assurances of his friendship and protection. He told him he would there meet with better accommodations, and as much security as in the mines; and that, should he chance to be discovered, he would, with all his friends and vassals, take arms in his defence.

Has a very narrow escape from the Danes.

This offer Gustavus very gladly embraced, and he remained for some time at his friend's house; but finding it impossible to induce him to take part in his designs, he quitted him, and fled to one Peterson, a gentleman whom he had formerly known in the service. This man received Gustavus with all the appearance of kindness; and on the very first proposal, offered to raise his vassals. He even named the nobles and peasants whom he pretended to have engaged in his service; but in a few days he secretly went to a Danish officer, and gave him information of what had passed. The officer immediately caused the house to be surrounded with soldiers, in such a manner that it seemed impossible for Gustavus to escape. Being warned by Peterson's wife of the treachery of her husband, he, by her direction, contrived to fly to the house of a clergyman, her friend, by whom he was received with all the respect due to his birth and merit; and lest the domestic who conducted him should follow the treacherous example of his master, he removed him to the church, and conducted him to a small closet, of which he kept the key. Having lived for some time in this manner, Gustavus began to consult with his friend concerning the most proper method of putting their schemes in execution. The priest advised him to apply directly to the peasants themselves; told him that it would be proper to spread a report that the Danes were to enter Dalecarlia in order to establish new taxes by force of arms; and as the annual feast of all the neighbouring villages was to be held in a few days, he could not have a more favourable opportunity. He also promised to engage the principal persons of the diocese in his interest.

His cause espoused by the peasants of Dalecarlia.

The Danes defeated.

In compliance with his advice, Gustavus repaired to Mora, where the feast was to be held. He found the peasants already informed of his designs, and impatient to see him. Being prepossessed in his favour, they were soon excited to enthusiasm in his cause, and instantly resolved to throw off the Danish yoke. In this design they were more confirmed by their superstition; some of their old men having observed that the wind had blown from the north while Gustavus was speaking, which among them was reckoned an infallible omen of success. Gustavus did not allow their ardour to cool, but instantly led them against the governor's castle, which he took by assault, and put the garrison to the sword. This inconsiderable enterprise was attended with the most happy consequences. Great numbers of the peasants flocked to his standard; some of the gentry openly espoused his cause, and others supplied him with money. Christiern was soon informed of what had passed; but despising such an inconsiderable enemy, he sent only a slender detachment to assist his adherents in Dalecarlia. Gustavus advanced with 5000 men, and defeated a body of Danes; but he was strenuously opposed by the archbishop of Upsala, who raised numerous forces for Christiern. The fortune of Gustavus, however, still prevailed, and the archbishop was defeated with great loss. Gustavus then laid siege to Stockholm; but his force being unequal to such an undertaking, he was forced to abandon it with loss.

Horrid cruelty of King Christiern.

Success of Gustavus.

This check did not prove in any considerable degree detrimental to the affairs of Gustavus: the peasants from all parts of the kingdom flocked to his camp, and he was joined by a reinforcement from Lübeck. Christiern, unable to suppress the revolt, wreaked his vengeance on the mother and sisters of Gustavus, whom he put to death. His barbarities served only to make his enemies more resolute. Gustavus having assembled the states at Wadstena, he was unanimously chosen regent, the diet taking an oath of fidelity to him, and promising to assist him to the utmost. Having thus obtained the sanction of legal authority, he pursued his advantages against the Danes. A body of troops appointed to throw succours into Stockholm was cut in pieces; and the regent sending some forces into Finland, struck the Danes there with such terror, that the archbishop of Upsala, together with the Danish governors, fled to Denmark. Christiern then sent express orders to all his governors and officers in Finland and Sweden, to massacre the Swedish gentry without distinction. The Swedes made reprisals by massacring all the Danes that they could find, so that the country was filled with slaughter.

In the mean time Gustavus had laid siege to the towns of Calmar, Abo, and Stockholm; but Norby found means to oblige him to retire with loss. Gustavus, in revenge, laid siege to the capital a third time, and applied to the regency of Lübeck for a squadron of ships and other succours for carrying on the siege. This request was granted on condition that Gustavus should oblige himself, in the name of the states, to pay 60,000 marks of silver as the expense of the armament; that, until the kingdom should be in a condition to pay that sum, the Lübeck merchants trading to Sweden should be exempted from all duties on imports or exports; that all other nations should be prohibited from trading with Sweden, and that such traffic should be deemed illicit; that Gustavus should neither conclude a peace, nor even agree to a truce, with Denmark, without the concurrence of the regency of Lübeck; and that if the republic should be attacked by Christiern, he should enter Denmark at the head of 20,000 men. On these hard terms Gustavus obtained assistance from the regency of Lübeck; nor did his dear-bought allies prove very faithful. They did not indeed transfer their services to his enemy; but in a sea-fight, where the Danes were entirely in their power, they suffered them to escape, when their whole force might have been entirely destroyed. This treachery had nearly ruined the affairs of Gustavus; for Norby was now making preparations effectually to relieve Stockholm, and would probably have succeeded in the attempt, if at this critical period news had not arrived that the Danes had revolted, and driven Christiern from the throne; and that the king had retired into Germany, in hopes of being restored by the arms of his brother-in-law the emperor. On hearing this intelligence, Norby retired with his whole fleet to the island of Gothland, leaving but a slender garrison in Calmar. Gustavus did not fail to improve this opportunity to his own advantage, and quickly made himself master of the town. In the mean time Stockholm continued closely invested, but he thought proper to protract the siege till he should be elected king. Having for this purpose called a general diet, he first filled up the vacancy in the senate occasioned by the massacres of Christiern. He had the address to procure the nomination of such as were in his interest. The assembly was no sooner met, than one of his partisans made a speech, containing the highest encomiums on Gustavus, setting forth in the strongest terms the many eminent services which he had rendered to his country, and concluding that the states would show themselves equally ungrateful and blind to their own interest if they did not immediately elect him king. This proposal was acceded to by such tumultuous acclamations that it was impossible to collect the votes; so that Gustavus himself acknowledged, that their affection exceeded his merit, and was more agreeable to him than the effects of their gratitude. He was urged to have the ceremony of his coronation immediately performed; but this he delayed, in consequence of some designs which he had formed to reduce the exorbitant power of the clergy. He had himself embraced the doctrines of the reformed religion, and did all in his power to establish the reformation in his new kingdom. His design could not fail to raise against him the enmity of the clergy, and of all the more superstitious part of his subjects. The first years of his reign were accordingly embittered by internal disturbances and revolts, which were aided and fomented by the deposed Christiern, who was at one time very near regaining possession of the Swedish dominions.

He is chosen king of Sweden. A. D. 1523.

Christiern having established a powerful interest in Norway, once more made an attempt to recover his kingdoms, and was joined by the Dalecarlians; but being defeated by the Swedish forces, he was compelled to return to Norway, where, being obliged to capitulate with the Danish generals, he was detained in captivity during the remainder of his life.

Unsuccessful attempt of Christiern.

In 1542, Gustavus having happily extricated himself out of all his troubles, prevailed on the states to make the crown hereditary in his family; after which he applied himself to the encouragement of learning and commerce. A treaty was set on foot for a marriage between his eldest son Eric and the princess Elizabeth of England; but this negociation failed of success.

Unsuccessful negociation for a marriage with Queen Elizabeth. A. D. 1542.

Gustavus Vasa died in 1560, and was succeeded by his son Eric XIV. The new king was possessed of all the exterior ornaments which gave an air of dignity to the person, but he had neither the prudence nor the penetration, of his father. He created the first nobility that were ever known in Sweden; but this he had no sooner done than he quarrelled with them, by passing some act which they thought derogatory to their honour and dignity. The whole course of his reign was disturbed by wars with Denmark and disputes with his own subjects. In the former he was unfortunate, and towards the latter he behaved with the greatest cruelty. At last, he is said to have become mad. He afterwards recovered his senses, but was soon dethroned by his brothers; one of whom, named John, succeeded him in the kingdom.

Gustavus dies, and is succeeded by Eric A. D. 1560.

Eric deposed, and succeeded by his brother John.

This revolution took place in the year 1568, but with no great advantage to Sweden. Disputes about religion between the king and his brothers, and wars with Russia, threw matters into the utmost confusion. Prince Sigismund, the king's son, was chosen king of Poland, which proved the source of much trouble to the kingdom. In 1590 King John died, and as Sigismund was at a distance, public affairs fell into the utmost confusion; the treasury was plundered, and the royal wardrobe spoiled, even before Duke Charles could come to Stockholm to undertake the administration till King Sigismund should return. This however was far from being the greatest disaster which befell the nation at this time. It was known that the king had embraced the popish religion, and it was with good reason suspected that he would attempt to restore it upon his arrival in Sweden. Sigismund was also obliged, on leaving Poland, to promise that he would remain no longer in Sweden than was necessary to regulate his affairs. These circumstances served to alienate the minds of the Swedes from their sovereign, even before they saw him; and the universal dissatisfaction was increased by seeing him attended on his arrival in Sweden in 1593 by the pope's nuncio, to whom he made a present of 30,000 ducats to defray the expenses of his journey to Sweden.

Prince Sigismund chosen king of Poland. A. D. 1568.

Succeeds to the crown of Sweden. A. D. 159

What the people had foreseen was too well verified. The king refused to confirm the protestants in their religious privileges, and showed such partiality on all occasions to the papists, that a party was formed against him, at the head of which was Duke Charles, his uncle. Remonstrances, accompanied with threats, took place on both sides. Sigismund was apparently reconciled to his uncle, and promised to comply with the inclinations of the people, though without any inclination to perform what he had promised. The agreement indeed was scarcely made, before Sigismund conceived the horrid design of murdering his uncle at the Italian comedy acted the night after his coronation. The duke, however, having notice of the plot, found means to defeat it. This enraged the king so much, that he had resolved to accomplish his designs by force; and he therefore commanded a Polish army to march towards the frontiers of Sweden, where they committed all the ravages that could be expected from an enraged and cruel enemy. Complaints were made by the protestant clergy to the senate; but no other answer was returned than that, till the king's departure, they should abstain from those bitter invectives and reproaches, which had provoked the Catholics, and that during his absence they would be at more liberty.

A party formed against him.

Forms a design of murdering his uncle.

In 1595 Sigismund set sail for Dantzig, leaving the administration in the hands of Duke Charles. The consequence of this was, that the dissensions which had already taken place being continually increased by the obstinacy of the king, Charles assumed the sovereign power; and in 1604 Sigismund was formally deposed, and his uncle Charles IX. raised to the throne. He proved a wise and brave prince, restoring the tranquillity of the kingdom, and carrying on a war with vigour against Poland and Denmark. He died in 1611, leaving the kingdom to his son, the celebrated Gustavus Adolphus.

Sigismund deposed, and is succeeded by Charles IX. A. D. 1604.

Though Charles IX. by his wise and vigorous conduct had in some measure retrieved the affairs of Sweden, they were still in a very bad condition. The finances of the kingdom were entirely drained by a series of wars and revolutions; powerful armies were preparing in Denmark, Poland, and Russia, while not only the Swedish troops were inferior in number to their enemies, but the government was destitute of resources for their payment. Though the Swedish laws required that the prince should have attained his eighteenth year before he was of age, yet such striking marks of the great qualities of Gustavus appeared, that he was allowed by the states to assume the administration before this early period. His first act was to resume all the crown-grants, in order that he might be enabled to carry on the wars in which he was engaged, and to fill all places, both civil and military, with persons of merit. At the head of domestic and foreign affairs was placed the chancellor Oxenstiern, a person every way equal to the important trust, and the choosing of whom impressed Europe with the highest opinion of the young monarch's penetration.

State of Sweden on the accession of Gustavus Adolphus. A. D. 1611.

He invades Denmark, and obliges the king to conclude a peace.

Russia invaded with success.

Extraordinary military genius of the king.

Soon after his accession, Gustavus received an embassy from James I. of Britain, exhorting him to make peace with his neighbours. This was seconded by another from Holland. But as the king perceived that the Danish monarch intended to take every opportunity of crushing him, he resolved to act with such vigour as might convince him that he was not easily to be overcome. Accordingly, he invaded Denmark with three different armies at once; and though the enemy's superiority at sea gave them great advantages, and the number of the king's enemies distracted his attention, he carried on the war with such spirit, that, in 1613, a peace was concluded on terms favourable to himself. This war being finished, Gustavus applied himself to civil polity, and made some reformation in the laws of Sweden. In 1615, hostilities were commenced against Russia, on account of the refusal of that court to repay some money which had been formerly lent. The king entered Ingria, took Kexholm by storm, and was laying siege to Plescov, when, by the mediation of James I., peace was concluded, on condition of the Russians repaying the money, and yielding to Sweden some part of their territory. In this and the former war, notwithstanding the shortness of their duration, Gustavus learned the rudiments of the military art, for which he soon became so famous. He is said to have taken every opportunity of improvement with a quickness of understanding seemingly more than human. In one campaign, he not only learned, but improved, all the military maxims of La Gardie, a celebrated general; brought the Swedish army to a more steady and regular discipline; and formed an invincible body of Finlanders, who had afterwards a very considerable share in the victories of Sweden.

Peace was no sooner concluded with Russia, than Gustavus was crowned with great solemnity at Upsala. Soon afterwards he ordered his general La Gardie to acquaint the Polish commander Codekowitz, that as the truce between the two kingdoms, which had been concluded for two years, was now expired, he desired to be certainly informed whether he was to expect peace or war from his master. In the mean time, having borrowed money of the Dutch for the redemption of a town from Denmark, he had an interview on the frontiers with Christiern, the king of that country. At this interview, the two monarchs conceived the utmost esteem and friendship for each other; and Gustavus obtained a promise, that Christiern would not assist Sigismund in any design he might form against Sweden. In the mean time, receiving no satisfactory answer from Poland, Gustavus began to prepare for war. Sigismund entered into a negociation, and made some pretended concessions, with a view to seize Gustavus by treachery; but the latter having some intimation of his design, the whole negociation was changed into reproaches and threats on the part of Gustavus.

Prepares for war with Poland.

Marries a daughter of the elector of Brandenburg.

Riga besieged and taken.

Immediately after this, Gustavus made a tour in disguise through Germany, and married Eleonora the daughter of the elector of Brandenburg. He then resolved to enter heartily into a war with Poland; and with this view set sail for Riga with a great fleet, which carried 20,000 men. The place was well fortified, and defended by a body of veterans, enthusiastically attached to Sigismund; but after a vigorous siege, the garrison, being reduced to extremity, were obliged to capitulate, and were treated with great clemency.

After the reduction of Riga, the Swedish monarch entered Courland, where he reduced Mittau; but ceded it again on the conclusion of a truce for one year. Sigismund, however, no sooner had time to recover himself, than he began to form new enterprises against the Swedes in Prussia; but Gustavus setting sail with his whole fleet for Dantzig, where the king of Poland then resided, so defeated his measures, that he was obliged to prolong the truce for another year. Sigismund was not yet apprised of his danger, and refused to listen to any terms of accommodation: Gustavus entering Livonia, defeated the Polish general, and took Dorpat, Hockenhausen, and several other places of less importance; after which, entering Lithuania, he took the city of Birsen. Notwithstanding this success, Gustavus proposed peace on the same equitable terms as before; but Sigismund was still infatuated with the hopes that, by means of the emperor of Germany, he should be able to conquer Sweden. Gustavus finding him inflexible, resolved to push his good fortune. His generals, Horn and Thurn, defeated the Poles in Semigallia. Gustavus himself, with 150 ships, set sail for Prussia, where he landed at Pillau. This place was immediately surrendered to him, as were several other towns. Sigismund, alarmed at the great progress of Gustavus, sent a body of forces to oppose him, and to prevent Dantzig from falling into his hands. But this measure did not produce any powerful effect; and in May 1627, Gustavus arrived with fresh forces before Dantzig, which he would probably have carried, had he not been wounded in the belly by a cannot-shot. The states of Holland sent ambassadors to mediate a peace between the two crowns; but Sigismund, depending on the assistance of the emperor of Germany and king of Spain, determined to hearken to no terms, and resolved to make a winter campaign. The king of Sweden was however so well intrenched, and all his forts were so strongly garrisoned, that the utmost efforts of the Poles were to no purpose. The city of Dantzig, in the mean time, made such a desperate resistance as greatly irritated him. In a sea engagement the Swedish fleet defeated that of the enemy; after which Gustavus, having blocked up the harbour with his fleet, pushed his advances on the land side with incredible vigour. He made a surprising march over a morass fifteen miles broad, assisted by bridges of a peculiar construction, over which he carried a species of light cannon invented by himself. By this unexpected manœuvre he obtained the command of the city in such a manner, that the garrison were on the point of surrendering, when, by a sudden swell of the Vistula, the Swedish works were ruined, and the king was obliged to raise the siege. In other respects, however, the affairs of Gustavus proceeded with their usual good fortune. His general Wrangel defeated the Poles before Brodnitz. At Stum the king gained another and more considerable victory in person. The emperor had sent 5000 foot and 2000 horse under Arnheim, who joined the main army commanded by the Polish general Coniecspolski, in order to attack the Swedish army encamped at Quidzin. The enemy were so much superior in number, that the friends of Gustavus warmly dissuaded him from attacking them. But the resolution of the king was not to be shaken, and the engagement commenced. The Swedish cavalry charged with such impetuosity, contrary to their sovereign's express order, that they were almost surrounded by the enemy; but, coming up to their assistance, he pushed the enemy's infantry with so much vigour, that they gave way, and retreated to a bridge that had been thrown over the Werder. But here they were disappointed, for the Swedes had already taken possession of the bridge. A new action ensued, more bloody than the former, in which the king was exposed to great danger, and thrice narrowly escaped being taken prisoner; but at last the Poles were totally defeated, and with immense loss. The slaughter of the German auxiliaries was so great, that Arnheim scarcely carried off one half of the troops which he brought into the field. This defeat did not hinder the Polish general from attempting the siege of Stum; but here he was as unsuccessful as in his previous enterprises. Arnheim was recalled, and was succeeded by Henry of Saxe-Lauenburg and Philip Count Mansfeldt. The change of general officers, however, produced no good consequences to the Poles; a famine and plague raged in their camp, so that they were at last obliged to consent to a truce for six years, to expire in the month of June 1635.

The Poles defeated.

The Poles defeated a third time. A. D. 1627.

The Poles defeated by sea, and Dantzig invested.

The king obliged by an inundation of the Vistula to raise the siege.

The Poles and Germans defeated with great slaughter in two engagements.

They are again defeated, and obliged to consent to a truce of six years.

Gustavus kept the port and citadel of Memel, the harbour of Pillau, the towns of Elbing, Brunsberg, and all that he had conquered in Livonia.

Gustavus resolves on a war with the emperor.

Gustavus having thus brought the war with Poland to an honourable conclusion, began to think of resenting the conduct of the emperor in assisting his enemies and oppressing the protestant states. Before embarking in such an important undertaking, it was necessary that he should consult the diet. Here the propriety of engaging in a war with Germany was warmly debated; but, after much altercation, the king, in a very noble speech, determined the matter, having declared in such strong terms the virtuous motives by which he was actuated, that the whole assembly wept, and every thing was granted which he could require.

Reduces Wolgast, Stettin, &c. A. D. 1630.

It was not difficult for him to begin his expedition. His troops amounted to 60,000 men, hardened by a succession of severe campaigns in Russia, Finland, Livonia, and Prussia. His fleet exceeded seventy sail, carrying from twenty to forty guns, and manned with 6000 seamen. Embarking his troops, he landed at Usedom on the 24th of June 1630, the Imperialists having evacuated all the fortresses which they there possessed; and the isle of Rugen had been before reduced by General Lesley, in order to secure a retreat if fortune should prove unfavourable. Passing the strait, Gustavus stormed Wolgast, and another strong fortress in the neighbourhood, leaving a garrison for the defence of these conquests. He then proceeded to Stettin, which consented to receive a Swedish garrison, and the king persuaded the duke of Pomerania to enter into an alliance with him. In consequence of this the Swedish troops were received into several towns of Pomerania; and the most bitter enmity took place between the Imperialists and Pomeranians.

Count Tilly the emperor's general.

Cuts off 2000 Swedes.

Frankfurt and Landsberg taken by Gustavus.

These successes of Gustavus struck the empire with consternation; for, being already overwhelmed with civil dissensions, they were in no condition to resist so impetuous an enemy. At last Count Tilly was invested with the dignity of field-marshal. In the mean time, the king, being reinforced by a considerable body of troops in Finland and Livonia under the conduct of Gustavus Horn, defeated the Imperialists before Griffenhagen, and soon afterwards took the place by assault. By this and some other conquests, he opened a passage into Lusatia and Silesia; but in the mean time Tilly cut off 2000 Swedes at New Brandenburg. This advantage, however, was soon overbalanced by the conquest of Frankfurt on the Oder, which Gustavus took by assault, making the whole garrison prisoners. Thus he commanded the rivers Elbe and Oder on both sides, and had a fair passage, not only to the countries already mentioned, but also to Saxony and the hereditary dominions of the house of Austria. He soon afterwards laid siege to Landsberg, which he took by assault.

He reduces Pomerania, and restores the dukes of Mecklenburg.

About this time the protestant princes held a diet at Leipzig, to which Gustavus sent deputies, and conducted his negociations with such address as tended greatly to promote his interests. Immediately after this he reduced Greifswald, and with it all Pomerania. Having then marched to Gustrow, he restored the dukes of Mecklenburg to their dominions.

Magdeburg taken by the Imperialists, and the inhabitants cruelly used.

All this time Tilly was employed in the siege of Magdeburg; but being alarmed at the repeated successes of the Swedes, he now left Pappenheim with part of the army before that city, while he marched with the rest into Thuringia, to attack the landgrave of Hesse-Cassel and the elector of Saxony. After a most obstinate defence, Magdeburg fell into the hands of Pappenheim, who committed all imaginable cruelties. The king formed a plan of recovering the city; but was obliged to abandon it, by Pappenheim's throwing himself into the place with his whole army, and by the progress which Tilly was making in Thuringia. Relinquishing this enterprise, he ordered an attack on Havelsburg; which was conducted with such resolution, that the place was forced in a few hours, and all the garrison made prisoners. Werben was next obliged to submit after an obstinate conflict, in which many fell on both sides. These successes obliged Tilly to attempt in person to check the progress of the Swedes. He detached the vanguard of his army, composed of the flower of the Imperial cavalry, within a few miles of the Swedish camp. An action ensued, in which Bernstein the Imperial general was defeated and killed, with 1500 of his men. Gustavus, after this advantage, placed himself in a situation so much superior to that of his enemies, that Tilly was fired with indignation, and marched up to the Swedish lines to give him battle. The king kept within his works, and Tilly attacked his camp, though almost impregnably fortified, and maintained a most terrible fire from a battery of thirty-two pieces of cannon; which, however, produced no other effect than obliging the Swedish monarch to draw up his army behind the walls of Werben. Tilly had placed his chief hopes in being able to spike the enemy's cannon, or set fire to their camp; after which he proposed making his grand attack. With this view he bribed some prisoners; but they betrayed him, and communicated his design to Gustavus. The king ordered fires to be lighted in different parts of his camp, and his soldiers to imitate the noise of a tumultuous disorderly rabble. This had the desired effect. The count led his army to the breach made by the cannon, where he was received with such a volley of grape-shot as cut off the first line, and put the whole body in disorder, so that they could never be brought back to the charge. In this confusion the Imperial army was attacked, and after an obstinate conflict obliged to quit the field.

Havelsburg and Werben reduced, and the cavalry of the Imperialists defeated by the Swedes.

Count Tilly defeated by Gustavus.

A body of British soldiers comes to the assistance of the Swedes.

Soon after this action the queen arrived at the camp with a reinforcement of 8000 men; at the same time a treaty was concluded with Charles I. of England, by which that monarch allowed the marquis of Hamilton to raise 6000 men for the service of Gustavus. These auxiliaries were to be conducted to the main army by a body of 4000 Swedes; and were in every thing to obey the king while he was personally present, but in his absence were to be subject to the orders of the marquis. With these troops the king had resolved to make a diversion in Bremen; but the marquis finding it impossible to effect a junction with the Swedish army, resolved, without debarking his troops, to steer his course for the Oder, and land at Usedom. Gustavus was very much displeased at finding his project thus disconcerted; but making the best of the present circumstances, he commanded the British troops to act on the Oder instead of the Weser. The number of this little army was magnified exceedingly by report, insomuch that Tilly had some thoughts of marching against them with his whole force; but on the departure of the marquis for Silesia, he reinforced the army in that country with a large detachment, which was thought to contribute not a little to the defeat which he soon after received.

Saxony ravaged by Count Tilly, who takes Leipzig.

Since the late action Gustavus had kept within his intrenchments, where his army was well supplied with provisions and stores. Tilly made several attempts to surprise or draw him to an engagement; but finding all his endeavours fruitless, he marched into Saxony, and laid siege to Leipzig. This precipitate measure proved highly advantageous to the Swedish monarch. A treaty offensive and defensive was immediately concluded with Gustavus; and the elector willingly promised every thing that was required of him. Tilly, in the mean time, carried fire and sword into the electorate. At the head of an army of 44,000 veterans, he summoned the city of Leipzig to surrender; denouncing, in case of a refusal, the same vengeance against it as had been executed on Magdeburg. The governor was so much intimidated, that he instantly submitted; and he also surrendered the castle of Passenberg, which was in a

Battle of Leipzig. A. D. 1631.

The Imperialists defeated with great slaughter.

condition to have resisted till the arrival of the Swedish army. The elector, enraged at the loss of these valuable places, ordered his army to join the Swedes with all expedition, and pressed the king so warmly to engage, that at last he yielded to his desire. On the 7th of September 1631, Gustavus led out his army in the finest order, the Swedes forming one column on the right, and the Saxons another on the left; each amounting to 15,000 men. Tilly drew up his men in one vast column, probably with a view of surrounding the flanks of the king's army. The king led his troops against that wing of the Imperialists commanded by Pappenheim, whom he drove back to a considerable distance. General Bannier in the mean time cut in pieces the troops of Holstein, and mortally wounded the duke, who commanded them. Pappenheim conducted his troops seven times to the charge, but was as often repulsed by the Swedes. Tilly all this while was engaged with the Saxons; but having at last driven them off the field, the whole strength of the Imperial army was turned against the Swedish left wing. The Swedes sustained the attack with the greatest firmness, until the king detached the centre to assist them. The Imperialists then were no longer able to maintain their ground; but gave way everywhere except in the centre, which was composed of eighteen regiments of veterans accustomed to victory, and deemed invincible. They made incredible efforts to maintain their reputation; and, though swept off in great numbers by the Swedish artillery, never shrunk or fell into confusion. Four regiments, after their officers had been killed, formed themselves, and withdrew to the skirt of a wood. Tilly retired at the head of 600 men, and escaped by the coming on of the night. Seven thousand Imperialists lay dead on the field of battle; 4000 were taken prisoners; a fine train of artillery was lost, with upwards of 100 standards, ensigns, and other military trophies.

The Swedes take a number of towns, and cut off four regiments of the enemy.

Gustavus now determined to penetrate into Franconia, where he reduced several places, especially the fortress of Würzburg. Tilly having collected his scattered troops, which formed an army still superior in number to that of Gustavus, marched to the relief of this place, but came too late. He then directed his march towards Rottenberg, where four regiments were cut in pieces by a Swedish detachment. After this, the king reduced Hanau, Frankfurt on the Maine, and Mentz, having destroyed a body of Spaniards who had attempted to obstruct his passage.

Wallenstein chosen general by the emperor.

The court of Vienna was now thrown into the utmost confusion, and sent everywhere begging assistance, and soliciting the Catholic princes to arm in defence of their religion. The emperor was most embarrassed in finding a general capable of opposing Gustavus in the field; for the late misfortunes of Count Tilly had entirely sunk his reputation. Wallenstein, an old experienced officer, was selected; but as he had formerly been disgraced, it was apprehended that he would not accept of the command of which he had once been deprived. This objection however was surmounted; and Wallenstein not only accepted of the command, but, at his own expense, augmented the army to 40,000 men.

A great number of towns taken by the Swedes.

Count Tilly defeated and killed.

Three towns laid in ashes by the Swedes.

During the whole winter the Swedish army kept the field, and before the approach of summer had reduced a great number of places, while the landgrave William made great progress in Westphalia. Gustavus Horn was repulsed before Bamberg, but soon had his revenge, by entirely destroying two regiments of Imperialists. To prevent the troops from being affected by the loss before Bamberg, the king resolved to give battle to Tilly, who was marching into Bavaria to prevent the Swedes from gaining a footing in that electorate. He pursued the Imperial general through a vast tract of country, defeated his rearguard, and having reduced a variety of towns and fortresses on the Danube, penetrated as far as Ulm. Advancing to the river Leck, the count posted himself in a wood on the opposite side, to dispute his passage. Gustavus endeavoured to dislodge him by a regular fire from seventy pieces of cannon. The slaughter was dreadful; and Tilly himself, being wounded by a cannon-ball in the knee, died a few days before he was to have been superseded by Wallenstein. The following night the Imperial army evacuated the post. Gustavus immediately crossed the river, and seized the towns of Rain and Neuburg, which the enemy had abandoned, and Augsburg next submitted. From Augsburg the Swedes advanced towards Ratisbon, but were disappointed in their design of obtaining possession of that city, as the Bavarians had thrown a numerous garrison into the place. In the mean time, ambassadors arrived from Denmark, offering the mediation of that crown for obtaining a lasting peace between the contending parties. This negociation however failed of success, as the ambassadors had not been instructed to offer terms favourable to the protestants. Gustavus, now resolving to retort on themselves the cruelties which the Bavarians had inflicted on the protestants, laid the towns of Morzburg, Friesengen, and Landshut, in ashes. The inhabitants of Munich saved themselves by submission. Gustavus also defeated the forces of the elector, who had been joined by a considerable body of militia.

The Saxon troops defeated by Wallenstein.

Gustavus attacks his camp, and is repulsed with loss.

Battle of Lützen.

Gustavus killed.

While the king was thus employed, Wallenstein had assembled a very numerous army. He was strongly solicited by the elector of Bavaria to come to his assistance; but, in revenge of the elector's having formerly obtained the command for Tilly in preference to himself, he drew off towards Bohemia to encounter the Saxons. Arnheim, who commanded the Saxon forces in that place, was an enemy to Gustavus, who had formerly rallied him for his cowardice. He therefore permitted Wallenstein to gain an easy victory, in hopes that his master, the elector of Saxony, a prince entirely devoted to his pleasures, might be induced to relinquish the friendship of such a restless and warlike ally as Gustavus; and indeed he used all the eloquence of which he was master to detach him from the Swedish cause. Several advantages were in the mean time gained by the Imperialists. Pappenheim defeated the archbishop of Bremen's cavalry at Werden; and three Swedish regiments were cut off near Kadingen. Pappenheim was however forced to retire, and to withdraw his forces from Stade, of which the Swedes took possession. Wallenstein and the elector of Bavaria, who had now joined their forces, threatened Gustavus with greatly superior numbers. The king, being reinforced with 15,000 men, no longer declined the engagement; but Wallenstein was too wise to trust the fate of the empire to a single battle against such an enemy as the king of Sweden. Gustavus attacked his camp, but was repulsed with the loss of 2000 men. Several other misfortunes happened to the Swedes; and at last, after various manœuvres, Wallenstein directed his course towards Misnia, in order to oblige the elector of Saxony to declare against the Swedes, and to draw them out of Bavaria. Gustavus, notwithstanding the inconstancy of Augustus, immediately set out to assist him. With incredible diligence he marched to Misnia, where the Imperialists were assembling their whole strength. Hearing that the enemy were encamped at Weissenfels, and that Pappenheim had been detached with a strong corps, Gustavus resolved to engage them before they could effect a junction. With this view he marched to Lützen, where he attacked Wallenstein with incredible fury. The Swedish infantry broke the Imperialists in spite of their utmost efforts, and took all their artillery. The cavalry not being able to pass the river so expeditiously as the king thought necessary, he led the way, attended only by a single regiment and the duke of Saxe-Lauenburg. Here, after charging impetuously, he was killed. The news of his death was in an instant spread over both armies. The courage of the Imperialists revived, and they now made themselves sure of victory. But the Swedes, eager to revenge the death of their beloved monarch, charged with such fury that nothing could resist them. The Imperialists were defeated a second time, just as Pappenheim, with his fresh corps, came up to their assistance. On this the battle was renewed, but the Swedes were still irresistible. Pappenheim was mortally wounded, and his army finally routed, with the loss of 9000 killed in the field and in the pursuit.

The Imperialists totally defeated.

Christina, an infant, proclaimed queen of Sweden.

This victory proved more unfortunate to Sweden than the greatest defeat. The crown devolved on Christina, the daughter of Gustavus, an infant of six years old; the nation was engaged in an expensive foreign war, without any person equal to the arduous task of commanding the armies, or regulating domestic affairs, as Gustavus had done. Christina was immediately proclaimed queen. The regency devolved on the grand bailiff, the marshal, the high admiral, the chancellor, and the treasurer of the crown. Oxenstiern was invested with the chief management of affairs, and conducted himself with the greatest prudence. The reign and character of Christina have been detailed under the article CHRISTINA, to which we may refer our readers.

Charles Gustavus appointed heir to the crown of Sweden.

From the treaty of Westphalia, Sweden enjoyed some years of repose. Charles Gustavus, Count Palatine, having gained the favour of Christina, was appointed generalissimo of the forces, and heir-apparent to the crown. A marriage was proposed between them; but the queen would never listen to this or any other proposal of the kind. In 1650, the ceremony of the queen's coronation was performed; but in four years after, she resigned the crown in favour of Charles.

A. D. 1654.

State of Sweden on the accession of Charles X.

The new king found himself involved in considerable difficulties on his accession to the throne. The treasury was quite exhausted; great part of the revenue was appointed for the support of Christina's household; the people were oppressed with taxes; and the nation having been disarmed for several years, began to lose its reputation among foreigners. To remedy these evils, Charles proposed to resume all the crown-lands which had been alienated by grants to favourites during the late reign; to repeal a duty which had been imposed on salt; to put the kingdom in a posture of defence; and to enter on a war with some neighbouring state. Under a pretence that Casimir king of Poland had questioned his title to the throne, he prepared to invade that kingdom. Several embassies were sent from Poland to Stockholm; but some point of ceremony always disappointed them of an audience of the king, so that they were obliged to return without executing their commission. As soon as matters were in readiness, General Wittemberg made an irruption into Poland from the side of Pomerania. The Poles opposed him with an army of 15,000 men; but instead of fighting, they began to negociate, and in a short time entirely dispersed. Charles himself soon followed with a powerful army, and pursued his march without obstruction, all the cities throwing open their gates to him as he approached. As he advanced to Cracow, Casimir resolved to make one effort to save his capital. His army amounted only to 10,000 men; and these were unfortunately such as had never stood fire. After a feeble resistance, they fled with precipitation, having lost 1000 men killed and taken prisoners. A few days after this Charles defeated the Poles a second time, about eight leagues from Cracow; on which Casimir fled with his family to Oppeln in Silesia. The capital was then invested, and, though defended with the utmost valour, was in a short time obliged to capitulate. Thus in less than three months Charles apparently became master of Poland; but it was soon evident that the Poles had no intention of abandoning their former sovereign.

War with Poland resolved on.

The Poles defeated, and the kingdom reduced.

War with the elector of Brandenburg.

A. D. 1656.

In 1656, a war took place with the elector of Brandenburg. While Charles was employed in the conquest of Poland, that prince had invaded Royal and Ducal Prussia, and reduced the most considerable towns with little opposition. The king of Sweden took umbrage at his progress; and having marched against him, defeated his forces in several slight encounters, and obliged him to acknowledge himself a vassal of Sweden. These rapid conquests alarmed all Europe; and the different powers sought for means of driving the Swedes out of Poland, which they had so unexpectedly and unjustly seized. The Poles were no sooner assured that they should obtain assistance, than they everywhere revolted and massacred the Swedes. Casimir returned from Silesia; and those very troops and generals who had before submitted to Charles without opposition, now ranged themselves under the banners of his antagonist. Charles immediately marched from Prussia to chastise the insolence of the Poles, and totally defeated a body of 12,000 men. This event did not hinder all the Poles incorporated with his troops to desert. Their defection considerably reduced his army; and the campaign being performed in the depth of winter, he was at last obliged to retreat to Prussia. In his march he was harassed by the Poles; and a body of 4000 Swedes was surprised and defeated by them at Warka. This loss however was soon after recompensed by a complete victory gained by Adolphus the king's brother, and General Wrangel. In the mean time the king was taking measures for laying siege to Dantzig; but was prevented by the Dutch, who threatened to oppose him, unless a proper regard was paid to their interest. Charles accordingly granted them advantageous terms; and afterwards gained over the elector of Brandenburg, by ceding to him the sovereignty of Prussia, that he might be at liberty to turn his whole strength against Poland.

The Poles revolt.

Charles gains a victory, but is obliged to retire.

Concludes a treaty with the Dutch and the elector of Brandenburg.

By the treaty just concluded with the elector, the latter was to assist Charles in his war with Poland; but the elector was so tardy in his measures, that the Poles, having obtained assistance from the Tartars, had reduced the city of Warsaw. The two princes now marched in concert against their enemies, who were encamped in a strong situation in the neighbourhood of the city above mentioned, their camp being fronted by the Vistula. The Poles were driven from their intrenchments with prodigious slaughter. The Poles and Tartars then laboured to break the alliance; and with which view, having entered Ducal Prussia, they defeated the electoral army, and took many prisoners. The Swedes soon obtained their revenge. General Steinboek attacked the same Polish army at Philippowa, and overthrew it with such slaughter as obliged the Poles for that season to quit the field. A more formidable enemy than the Poles now began to make their appearance. The Russians invaded the provinces of Carelia, Ingermania, and Livonia; while the elector of Brandenburg began to waver in his fidelity. To preserve this only ally at such a critical juncture, Charles was obliged to grant him more advantageous terms than those already mentioned; and the Russians were repulsed in the provinces of Carelia and Ingermania. But in Livonia they had better success. For seven months, however, they battered the walls of Riga, without venturing to pass the ditch or storm the practicable breaches.

The Poles and Tartars defeated with great slaughter.

The Russians invade the Swedish dominions.

Charles, notwithstanding the number of his enemies, was now become so formidable by the valour and discipline of his troops, that entire armies often fled on his approach. At last, in 1657, the Poles, finding they could not resist him in the field, contented themselves with harassing the Swedes on their march, and cutting off the foragers and convoys. This proved much more destructive to the Swedes than their former method; so that Charles was obliged to enter into an alliance with Ragotski, prince of Transylvania, by assigning him certain provinces in his neighbourhood, in order to furnish himself with irregular troops, who might fight the Poles in their own way. He did not thus obtain any real advantage; for the confederates, after wasting a whole

A. D. 1657.

Charles enters into an alliance with Ragotski, prince of Transylvania.

campaign in Lithuania, were obliged to retire without accomplishing more than the reduction of a single fortress. Charles then returned with the Swedish army to Prussia.

Leopold king of Hungary declares against Sweden.

Ragotski's army destroyed by the Poles and Tartars.

He is defeated and killed by the Turks.

Leopold, the young king of Hungary, having long beheld the Swedes with a jealous eye, now resolved to declare for Poland. The more effectually to curb the ambition of the Swedish monarch, he solicited the king of Denmark to come to a rupture with him. This application was attended with immediate success, and the Danes invaded Bremen. Charles hastened to oppose this new enemy, and he thus gave such offence to Ragotski, that, neglecting to take the proper measures for his own defence in the absence of the Swedes, he suffered his army to be destroyed by the Poles and Tartars. At the same time the Turks invaded Transylvania, under pretence that Ragotski, being a vassal of the grand signior, had no right to invade Poland without his permission. Ragotski, opposing them in the field, was defeated and killed, leaving Charles destitute of the only ally on whom he could depend.

Bravery and success of General Wrangel.

The house of Austria declares against Sweden.

The king, however, not dismayed by this misfortune, traversed Pomerania and the duchy of Mecklenburg; after which he attacked Holstein, while General Wrangel with another corps entered the duchy of Bremen. The general executed his measures with the utmost vigour. In fifteen days he retook all the towns which the enemy had reduced; defeated and drove the Danish army out of the country, killing 3000 of their best soldiers. In Holstein the king reduced several fortresses, laid Itzehoe in ashes, defeated a body of Danes, and laid siege to Frederic Udda, into which the Danes had thrown a strong garrison. Leaving to Wrangel the conduct of this siege, he himself retired to Wismar in order to observe the situation of affairs in Poland; and no sooner was he departed than Wrangel attacked the place with such fury, that he became master of it in two hours. In the province of Halland the Swedes were defeated, but the enemy derived no advantage from their victory. At sea the fleets met, and maintained an engagement for two days, without any considerable advantage on either side. In Poland affairs were not better conducted. The house of Austria had now declared for Casimir; and a German army having entered Poland, reduced Cracow, though not without sustaining great loss.

Charles invades Denmark with great success.

Peace concluded.
A. D. 1658.

The king of Sweden was now surrounded by enemies. The elector of Brandenburg had declared against him; and he had besides to engage the armies of Austria, Poland, Russia, and Denmark. In this dangerous situation he resolved to attack Denmark, so as to oblige that state to come to a speedy accommodation. His designs were forwarded by a very early frost, which enabled him to transport his troops without shipping. Having marched over the ice to the island of Funen, he cut in pieces a body of 4000 Danish soldiers and 500 peasants. The whole island was reduced in a few days; after which he passed to Langland, then to Laaland, after that to Falster, and lastly to Zealand. The Danes were terrified at this unexpected invasion, and were resigning themselves to despair, when Charles offered to conclude a peace on equitable terms. The king of Denmark gladly consented, intending to renew the war as soon as he thought it could be done with safety.

The war renewed, and Copenhagen besieged.

Charles was no sooner retired, than the king of Denmark began to act secretly against him; on which, resolving to anticipate him in his designs, he appeared unexpectedly with a fleet before Copenhagen. The Swedish monarch laid siege to the capital, but with so little prudence that he made no progress, and was at length compelled to turn the siege into a blockade, which continued to the end of the war. Charles X. died of an epidemic fever, and was succeeded by his son Charles XI.

Charles XI.
A. D. 1660.

Treaty of Olivia.

War with Brandenburg.

The Swedes defeated by land and sea.

A. D. 1676.

The new king, Charles XI. was a minor at the time of his father's death; and as the kingdom was involved in a dangerous war with so many enemies, the regency determined to conclude a peace, if it could be obtained on reasonable terms. A treaty was accordingly concluded at Olivia, by which Casimir renounced his pretensions to the crown of Poland, and that state gave up all pretensions to Livonia. Bornholm and Drontheim were ceded to Denmark, and an equivalent in Schonen remained with Sweden. During the minority of the king, nothing remarkable occurs in the history of Sweden. In 1672 he entered into alliance with Louis XIV. which two years after involved him in a war with the elector of Brandenburg. At first the Swedes carried all before them. Almost all the towns in Brandenburg were reduced, when the elector arrived with an army to the relief of his distressed subjects. He retook several towns, defeated the Swedes in a general engagement, and soon after forced them to abandon all their conquests. In conjunction with the Danes, he then invaded the Swedish dominions: many places of importance were reduced; and, in 1676, Sweden received a most destructive blow by the defeat of her fleet in an engagement with the combined fleets of Denmark and Holland. The king soon afterwards took the government into his own hands, and in some degree restored the fortune of Sweden; but although he was more successful where he commanded in person, the same losses and disgrace attended the Swedish arms in every other quarter. In 1678, the Swedish fleet was defeated in two engagements. At Landscrona a most obstinate battle was fought, from ten in the morning till six at night, when both parties were obliged, by fatigue, to retire to their respective camps. At Oldeval, in Norway, the Swedes were defeated; and the Danes laid desolate the islands of Oeland, Smaaland, Unno, and Kuno; while the electoral troops and Imperialists reduced Count Königsmark to the utmost distress in the neighbourhood of Stralsund. In this deplorable situation of affairs Königsmark found an opportunity of attacking his enemies to such advantage, that he obtained a complete victory; after which he ravaged the duchy of Mecklenburg. Notwithstanding this success, he could not prevent the elector from reducing Stralsund. He was afterwards obliged to evacuate Pomerania; and, to complete his distress, the fleet which transported the Swedish army from Pomerania was wrecked on the coast of Bornholm.

Peace concluded.

Charles becomes absolute.

At this unprosperous crisis a peace was concluded at St Germains between France and her enemies, by which the Swedes and Danes were left to decide their quarrel between themselves. Denmark was by no means a match for Sweden, even in the distressed situation to which she was reduced; and a treaty was therefore concluded, on terms much more favourable to Sweden than could have been expected. The peace was confirmed by a marriage between Charles, and Ulrica Eleonora, daughter to the king of Denmark. From this time the Swedish monarch applied himself to the reformation of the state; and by artfully managing the disputes between the nobility and the peasants, he obtained a decree empowering him to alter the constitution as he pleased. The proceedings of the king after this decree were such as to exasperate the nobility, and produce violent commotions. See Patkul.

Charles XI. dies, and is succeeded by his son Charles XII.

On the 15th of April 1697, died Charles XI. leaving his crown to his son, the celebrated Charles XII. at that time a minor. On his accession, he found himself under the tuition of his grandmother Eleonora, who had governed the kingdom during the minority of the late king. Though Charles was at that time only fifteen years of age, he showed a desire of taking the government into his own hands. His counsellors, Count Piper and Axel Sparre, signified his desire to the queen-regent. By her they were referred to the states, and there all were unanimous; so that the queen, finding that opposition would be vain, resigned her power with a good grace; and Charles was invested with absolute authority in three days after he had expressed his desire of

A powerful combination formed against him.

Holstein ravaged by the Danes. A. D. 1699.

They are repulsed at Tonningen.

reigning alone. He was scarcely seated on the throne when a powerful combination was formed against him. Augustus king of Poland formed designs on Livonia; the king of Denmark revived his disputes with the duke of Holstein, as a prelude to a war with Sweden; and Peter the Great of Russia began to form designs on Ingria, formerly a province of Russia. In 1699 the king of Denmark marched an army into Holstein. Charles sent a considerable body of troops to the duke's assistance; but before their arrival the Danes had ravaged the country, taken the castle of Gottorp, and laid close siege to Tonningen. Here the king of Denmark commanded in person, and was assisted by the troops of Saxony, Brandenburg, Wolfenbuttel, and Hesse-Cassel. Britain and Holland, as guarantees of the last treaty with Denmark, in concert with Sweden, joined Charles against this confederacy, and sent fleets to the Baltic. They proposed a termination of the war on equitable terms; but these were haughtily refused by the Danish monarch, who despised the youth and inexperience of Charles, and relied too much on the alliance which he had formed with Saxony, Brandenburg, Poland, and Russia. Tonningen, however, resisted all his efforts; and when he ordered the place to be stormed, he had the mortification to see his troops driven headlong from the walls by a handful of Swedes.

Charles defeats the fleet of the allies. A. D. 1700.

Obliges the Danes to make peace.

Marches against the Russians.

In the year 1700, Charles, having intrusted the affairs of the nation with a council chosen out of the senate, set out on the 8th May from his capital, to which he never afterwards returned. He embarked at Carlscrona, and defeated the fleet of the allies. Having made a descent on the island of Zealand, he defeated a body of cavalry that opposed his march, and then proceeded to invest Copenhagen by sea and land. The king of Denmark saw the necessity of either having his capital destroyed, or of doing justice to the duke of Holstein. He chose the latter; and a treaty was concluded on much the same terms as formerly. Charles, being thus at liberty to turn his arms against the other princes who had conspired his destruction, resolved to lead his army against Augustus king of Poland. On the road, however, he received intelligence that the czar of Russia was on his march to oppose him, and had laid siege to Narva with an army of 100,000 men. The contest that ensued between Charles and Peter, with the celebrated battles of Narva and Pultava, have been already related under RUSSIA, so that we shall here confine ourselves chiefly to those events in which Peter the Great was not immediately concerned. Peter was the chief support of Augustus, and he took the most active measures to oppose the progress of the Swedish monarch. His want of success, and the subsequent contests between him and Charles, till the decisive battles of Pultava, are related in the same article.

Charles marches against the Saxons, A. D. 1701,

and entirely defeats them.

Forms a scheme for dethroning Augustus.

In 1701, as early as the season permitted, Charles, having received a reinforcement from Sweden, took the field, and appeared suddenly on the banks of the Duna, along which the Saxon army was posted to receive him. The king of Poland being at that time sick, the army was commanded by Ferdinand duke of Courland, Marshal Stenau, and General Paykel, all officers of valour and experience. They had fortified some islands in the mouth of the river, and taken every other precaution against an attack; the soldiers were hardy, well disciplined, and nearly equal to the Swedes in number; yet Charles, having passed the river in boats with high sides, to screen the men from the fire of the enemy, attacked them with such fury, that they were entirely defeated, and with great loss. This victory was followed by the surrender of all the towns and fortresses in the duchy of Courland. Charles then passed into Lithuania, where every town opened its gates to him. At Birsen, an army of 20,000 Russians retired with the utmost precipitation on the news of his approach. Here Charles, perceiving that the kingdom of Poland was greatly disaffected to Augustus, began to project the scheme of dethroning him by means of his own subjects. This scheme he executed with more policy than he ever showed on any other occasion.

Warsaw taken.

The Saxons entirely defeated.

Cracow taken.

Remain of the Sax army entirely defeated. A. D. 17

Augustus, in the mean time, finding his scheme of peace frustrated, had recourse to the senate; but met with such a rough answer from them, that he determined to apply to Charles. To him therefore he sent his chamberlain; but a passport being forgotten, the ambassador was arrested. Charles continued his march to Warsaw, which surrendered on the first summons; but the citadel held out for some days. Augustus, finding at last that no dependence was to be placed on the Poles, determined to trust his fortune wholly to the Saxon army and the nobility of the palatinate of Cracow, who offered to support him to the utmost of their power. The Saxon army had now advanced to the frontiers, and Augustus immediately put himself at its head. Being joined by the nobility of Cracow, he found that his forces amounted to 30,000 men, all brave and well disciplined. With these he marched in quest of his enemy; nor did the Swedish monarch decline the combat, though he had with him only 12,000 men. Though the Saxons were strongly posted, having their front covered by a morass, besides being fortified with pallisadoes and chevaux de frise, they were attacked with irresistible impetuosity, and entirely defeated. This victory was followed by the loss of Cracow. Charles then set out in pursuit of the flying army, with a design of preventing them from re-assembling; but his horse falling under him, he had the misfortune to break his thigh, by which he was confined six weeks, and thus Augustus obtained some respite. He improved this interval. Having convoked a diet, first at Marienburg, and then at Lublin, he obtained the following resolutions; that an army of 50,000 men should be raised by the republic for the service of the prince; that six weeks should be allowed the Swedes to determine whether they were for war or peace; and that the same time should be granted to the turbulent and discontented nobles of Poland to make their concessions. To counteract the effects of these resolutions, Charles assembled another diet at Warsaw; and while the two assemblies disputed concerning their rights and privileges, he recovered from his wound, received a strong reinforcement from Pomerania, and utterly defeated and dispersed the remains of the Saxon army.

August deposed and Sta las raise to the throne.

Warsaw retaken by August

Excelle conduct his gene Schulle berg.

His en gageme with th Swedes

The ill fortune of Augustus continued still to prevail. In 1704 he was formally deposed by the diet, and the crown was conferred by Charles on Stanislas Lecsinsky, palatine of Posnania. Augustus however did not yet tamely relinquish his kingdom. His adherents daily skirmished with the Swedes; and Augustus himself, being reinforced by 9000 Russians, retook Warsaw, and had nearly surprised the new king, who lived in perfect security in the city while Charles fought his battles. Count Horn, with 1500 Swedes, vigorously defended the citadel; but at last, finding it no longer tenable, he was obliged to surrender at discretion. The reduction of Warsaw was among the last advantages gained by Augustus in the course of this war. His troops were now composed of Saxon recruits and undisciplined Poles, who had no attachment to his person, and were ready on all occasions to forsake him. Charles and Stanislas advanced with the victorious army; the Saxons fled before them, and the towns several miles round tendered their submission. The Poles and Saxons were under the command of Schullemberg, a most sagacious and experienced general, who used every expedient to check the progress of the Swedes. With all his conduct and caution he found himself outwitted, and Charles in the neighbourhood of his camp, ready to fall on him, while he thought him at fifty leagues distance. The Swedish monarch attacked him with a superior army, but entirely composed of horse. Schullemberg had posted his men in such a manner as rendered it impossible to surround them. His first rank, being armed with pikes and muskets, presented a rampart of bayonets; the

His fine retreat.

second line, stooping over the first, who kneeled, fired over their heads; while the third rank, who stood upon their feet, kept up an incessant fire, by which the Swedish horse were exceedingly galled and put in disorder. Charles lost the opportunity of cutting off the whole Saxon army, by omitting to order his men to dismount. This was almost the first time that infantry had been regularly opposed to cavalry, and the superiority of the former was evident. After the engagement had continued about three hours, the Saxons retreated in good order; which no enemy had ever done before in any engagement with Charles. The Swedes pursued their enemies towards the Oder, and forced them to retreat through thick woods, almost impervious even to infantry. The Swedish horse, however, pushed their way, and at last enclosed Schullemberg between a wood and the river, where Charles had no doubt of obliging him to surrender at discretion, or die sword in hand, as having neither boats nor bridges; but the genius of Schullemberg supplied every defect. In the night he ordered planks and floats of trees to be fastened together, on which he carried over his troops, while the Swedes were employed in dislodging 300 men, whom he had placed in a wind-mill for the purpose of defending his flank, and diverting the attention of the enemy. Charles spoke of this retreat with admiration, and said he had been conquered by Schullemberg.

Augustus leaves Poland.

The Russians take several towns in Livonia, and invade Poland.

Astonishing success of Charles against them.

Schullemberg entirely defeated by Renschild.

No material advantage however resulted to Augustus, who was again obliged to leave Poland, and fortify the capital of his hereditary dominions, which he expected every moment to see invested. In the mean time, the Russians having recovered their spirits, attacked the Swedes in Livonia with the utmost fury. Narva, Dorpat, and several other towns, were taken, and the inhabitants and garrison treated with great barbarity. An army of 100,000 Russians soon afterwards entered Poland. Sixty thousand Cossacks under Mazeppa entered the country at the same time, and committed every outrage with the fury of barbarians. Schullemberg, perhaps more formidable than either, advanced with 14,000 Saxons and 7000 Russians, disciplined in Germany, and reputed excellent soldiers. Could numbers have determined the event of war, the Swedes must certainly have been at this time overpowered; but Charles seemed to triumph over his enemies with more ease the more numerous they were. The Russians were so speedily defeated, that they were all dispersed before one party had notice of the misfortunes of another. The defeating an army of 40,000 men scarcely obstructed the march of the Swedes, while their astonished enemies looked on these actions as the effects of witchcraft, and imagined that the king of Sweden had dealings with infernal spirits. With these apprehensions they fled beyond the Dnieper, leaving the unhappy Augustus to his fate. Schullemberg, with all his skill and experience, was not more successful. The Swedish general Renschild engaged and defeated him in half an hour, though the Swedes were vastly inferior in number, and their enemies posted in a most advantageous situation. Nothing could be more complete than the victory. This extraordinary victory, indeed, is said to have been owing to a panic which seized the troops of Schullemberg; but it was regarded with admiration, and thought to make the renown of Renschild equal to that of his sovereign. Charles himself was jealous, and could not help exclaiming, "Surely Renschild will not compare himself with me!"

Charles invades Saxony.

Augustus begs for peace on any terms.

Charles's answer.

Soon after this victory, which was gained on the 12th of February 1706, Charles entered Saxony at the head of 24,000 men. The diet at Ratisbon declared him an enemy to the empire if he crossed the Oder. But to this declaration no regard was paid: Charles pursued his march, while Augustus was reduced to the condition of a vagrant in Poland, where he possessed not a single town except Cracow. Into this city he threw himself with a few Saxon, Polish, and Russian regiments, and began to erect some fortifications for his defence; but the approach of the Swedish general Meyerfeldt, and the news of the invasion of Saxony, disconcerted all his measures, and plunged him into despair. The Russians indeed were his faithful allies, but he dreaded them almost as much as the Swedes; so that he was reduced to the necessity of writing a letter to Charles with his own hand, begging for peace on whatever terms he thought proper to grant. As he was then at the mercy of the Russians, this transaction was concealed with the greatest care. His emissaries were introduced to the Swedish court in the night-time, and being presented to Charles, received the following answer: that King Augustus should for ever renounce the crown of Poland, acknowledge Stanislas, and promise never to re-ascend the throne, should an opportunity offer; that he should release the princes Sobieski, and all the Swedish prisoners made in the course of the war; surrender Patkul, at that time resident at his court as ambassador for the czar of Russia, and stop proceedings against all who had passed from his into the Swedish service. These articles Charles wrote with his own hand, and delivered to Count Piper, ordering him to finish them with the Saxon ambassadors.

Charles arrives in Turkey after his defeat at Pultava.

After his defeat at Pultava by the Russians, Charles fled in a mean calash, attended by a little troop inviolably attached to his person, some on foot, and some on horseback. They were obliged to cross a sandy desert, where neither herb nor tree was to be seen, and where the burning heat and want of water were more intolerable than the extremities of cold which they had formerly endured. The whole had almost perished for want of water, when a spring was fortunately discovered. They reached Otchakoff, a town in the Turkish dominions, the pacha of which supplied the king with every necessary. It was, however, some time before boats could be got ready for transporting the whole of the king's attendants; by which accident 500 Swedes and Cossacks fell into the hands of the enemy. This loss affected him more than all his other misfortunes. He shed tears at seeing, across the river Bog, the greater part of his few remaining friends carried into captivity, without having it in his power to assist them. The pacha waited on him to apologise for the delay, and was as severely reprimanded by Charles as if he had been his own subject.

Is kindly received, and his hopes of conquering Russia begin to revive.

Augustus recovers the kingdom of Poland.

The king remained but a few days at Otchakoff, when the seraskier of Bender sent an aga to compliment him on his arrival in the Turkish dominions, and to invite him to that city. Here he was treated with hospitality. The Turks practised to its full extent their generous maxim of regarding as sacred the persons of unfortunate princes who had taken shelter in their dominions; and they perhaps regarded him, notwithstanding his misfortunes, as an ally that might be useful to themselves against the Russians. Every one indeed regarded him in his distress. The French king offered him a safe passage from the Levant to Marseilles, from whence he might easily return to his own dominions. But Charles was too obstinate to receive advice. Puffed up with the notion of imitating Alexander the Great, he disdained to return except at the head of a numerous army; and he yet expected, by means of the Turks, to dethrone his adversary the czar. Negociations for this purpose were carried on in the Turkish divan, and it was proposed to escort Charles with a numerous army to the frontiers of Poland; but the revolution which there took place put an end to all such projects. Augustus thought himself no longer bound to observe the treaty which he had made, than when Charles was at hand to compel him. After the battle of Pultava, he entered Poland, and took every measure, in concert with the czar, for the recovery of his kingdom. Stanislas was not able to encounter such enemies, but was obliged to leave his dominions and fly to Bender, in the disguise of a Swedish officer, in order to share the

The Danes invade Sweden,

but are utterly defeated.

fortune of Charles. It was not in Poland alone that the Swedish affairs began to suffer in consequence of the defeat at Pultava. The Danes invaded the province of Schonen with an army of 13,000 foot and 2500 horse. Only 13,000 Swedish forces remained to defend all the territories possessed by Charles in Germany, and of these only a small part was allotted for the defence of Schonen. The regency of Sweden, however, exerted themselves to the utmost to repel this ungenerous invasion; and having collected an army of 12,000 militia and 8000 regulars, despatched them under General Steenboek into Schonen. Some Saxon troops were incorporated in this army; but among these a prodigious desertion took place, which the general found it impossible to prevent; and thus the Danes gained several advantages, and at last took Christianstadt. Their insolence on this success was so great that the Swedes demanded to be instantly led against them. Here the good fortune of Sweden seemed once more to revive. The Danes were driven from a very strong situation, with the loss of 8000 killed and taken prisoners, besides a vast number wounded. The king received the intelligence of this victory with the greatest exultation, and could not help exclaiming, "My brave Swedes, should it please God that I once more join you, we shall conquer them all."

The Turks declare war against the Russians. A. D. 1711.

In the mean time, Charles, by means of his agents the count Poniatoffski and Neugebar, used his utmost efforts to procure a rupture between the Porte and Russia. For a long interval the money bestowed by Peter on the vizirs and janisaries prevailed; but at last the grand signior, influenced by his mother, who was strongly in the interest of Charles, and had been used to call him *her lion*, determined to support his quarrel with Peter. He therefore gave orders to the vizir to fall on the Russians with an army of 200,000 men. The vizir promised obedience, but at the same time professed his ignorance in the art of war, and dislike to the present expedition. The khan of Crim Tartary, who had been gained over by the reputation and presents of the king of Sweden, had orders to take the field with 40,000 of his men, and had the liberty of assembling his army at Bender, that Charles might see that the war was undertaken on his account. See RUSSIA.

The treaty of the Pruth was most violently opposed by Poniatoffski and the khan of Tartary. The former had made the king acquainted with the situation of both armies; on which he instantly set out from Bender, filled with the hopes of fighting the Russians, and taking ample vengeance. Having ridden fifty leagues post, he arrived at the camp just as the czar was drawing off his half-famished troops. He alighted at Poniatoffski's tent; and being informed of particulars, instantly flew in a rage to the vizir, whom he loaded with reproaches, and accused of treachery. Recollecting himself, however, he proposed a method by which the fault might be remedied; but finding his proposal rejected, he posted back to Bender, after having by the grossest insults showed his contempt of the vizir.

The grand signior desires him to depart.

The violent behaviour of Charles did not promote his interest. The vizir perceived that his stay in Turkey might prove fatal to himself, and he therefore determined to remove him as soon as possible. Succeeding vizirs adopted the same plan; and at last the grand signior himself wrote a letter to Charles, in which he desired him to depart by next winter, promising to supply him with a sufficient guard, with money, and every thing else necessary for his journey. Charles gave an evasive answer, and determined to procrastinate his journey, as well to gratify his own stubborn temper, as because he discovered a correspondence between Augustus and the khan of Tartary, the object of which, he had reason to believe, was to betray him to the Saxons. When he was again pressed to fix the day of his departure, he replied, that he could not think of going before his debts were paid. Being asked how much was necessary for this purpose, he replied, a thousand purses. A purse, it is to be remarked, consists of thirty sequins. Twelve hundred purses were instantly sent to the seraskier at Bender, with orders to deliver them to the king of Sweden, but not before he should have begun his journey. By fair promises, Charles persuaded him to part with the money; after which, instead of setting out, he squandered away his treasure in presents and gratifications, and then demanded a thousand purses more before he would set out. The seraskier was astonished at this behaviour. He shed tears; and turning to the king told him that his head would be the forfeit of having obliged him with the money. The grand signior, on being acquainted with the shameful behaviour of Charles, flew into a rage, and called an extraordinary divan, where he himself spoke; a practice very unusual for the Turkish monarchs. It was unanimously agreed that such a troublesome guest ought to be removed by force, should other means fail. Positive orders were therefore sent to Charles to depart; and, in case of his refusal, instructions were given for attacking him in his quarters. Nothing could equal his obstinacy on this occasion: in spite of the menaces of his enemies, in spite of the entreaties of his friends, he persisted in his resolution; and at last determined to resist, with 300 Swedes, being the entire number of his attendants, an army of 20,000 janisaries well armed and furnished with cannon. At length he was attacked in good earnest; though it must be owned, that even in this extremity, the Turks showed their regard to him, and were tender of his safety. Most of the Swedes surrendered at once, perhaps as thinking it the only method of saving the king's life. This conduct, however, had an opposite effect. Charles became the more obstinate, the more desperate his affairs seemed to be. With only forty menial servants, and the generals Hord and Dardorff, he determined to defend himself to the last extremity. Seeing his soldiers lay down their arms, he told the generals, "We must now defend the house. Come," added he with a smile, "let us fight *pro aris et focis*." The house had been already forced by the Tartars, all but a hall which was near the door, and where his domestics had assembled. Charles forced his way through the janisaries, attended by the generals Hord and Dardorff, joined his people, and then barricaded the door. The moment he entered, the enemy who were in the house threw down their booty, and endeavoured to escape at the windows. Charles pursued them from room to room with much bloodshed, and cleared the house in a few minutes. He then fired furiously from the windows, killed two hundred of the Turks in a quarter of an hour, so that the pacha who commanded them was at length forced to set the house on fire. This was effected by discharging arrows with lighted matches into the roof; but Charles, instead of quitting his post, gave orders for extinguishing the fire, and he himself assisted with great diligence. All efforts were however vain: the roof fell in, and Charles, with his few faithful companions, was ready to be buried in the ruins. In this extremity one called out that there was a necessity for surrendering. "What a strange fellow!" cries the king, "who would rather be a prisoner with the Turks than mix his ashes with those of his sovereign." Another had the presence of mind to cry out, that the chancery was but fifty paces off, had a stone roof, and was proof against fire. Pleased with the thoughts of again coming to blows, the king exclaimed, "A true Swede! Let us take all the powder and ball we can carry." He then put himself at the head of his troops, and sallied out with such impetuosity, that the Turks retreated fifty paces; but having fallen in the midst of his fury, they rushed upon him, and carried him by the legs and arms to the pacha's tent. This extraordinary adventure, which savours not a little of insanity, happened on the 12th of February 1713. He was now kept prisoner with all his retinue; and in this situation he was visited by the unfortunate Stanislas, the dethroned king of Poland.

Begins to think of returning to his dominions.

Charles seemed at last inclined to submit to his fate, and began seriously to think of returning to his kingdom, now reduced to the most deplorable situation. His habitation had been fixed at Demotica, a small town about six leagues from Adrianople. Here he was allowed provisions for his own table and those of his retinue; but only twenty-five crowns a day in money, instead of five hundred which he had received at Bender. During his residence here, he received a deputation from Hesse-Cassel, soliciting his consent to the marriage of the landgrave with Eleonora, princess royal of Sweden; to which he readily agreed. A deputation was also sent him by the regency of Sweden, requesting that he would prepare for returning to his own dominions, which, in his absence, were ready to sink under a ruinous war.

Sets out for Sweden. A. D. 1714.

On the 14th of October 1714, Charles set out for Sweden. All the princes through whose territories he was to pass had given orders for his entertainment in the most magnificent manner; but the king, perceiving that these compliments only rendered his imprisonment and other misfortunes more conspicuous, suddenly dismissed his Turkish attendants, and assembling his own people, bid them take no care about him, but make the best of their way to Stralsund. After this he set out post, in the habit of a German officer, attended only by Colonel During. Keeping the by-roads through Hungary, Moravia, Austria, Bavaria, Wirtemberg, the Palatinate, Westphalia, and Mecklenburg, he arrived on the 21st of November at midnight before the gates of Stralsund. Being unknown, he was admitted with difficulty; but being soon recognised by the governor, the greatest tokens of joy were manifested all over the town.

Distressed situation of Sweden.

Sweden was now in the greatest distress. On the news of the defeat at Pultava, the Danes had invaded Schonen, but were defeated by General Steenboek. This victory did not, however, put an end to the war. The kings of Denmark and Poland, with the czar of Russia, entered into stricter bonds of amity than ever. They dreaded the return of Charles to his own dominions, and apprehended that numberless victories would soon efface the remembrance of Pultava. They determined to make the best use of their time; and perhaps Charles never took a more imprudent resolution than obstinately to remain so long in the Turkish dominions. His return seemed to give new life to the whole nation. Though the number of inhabitants was visibly diminished, the levies which he had ordered were completed in a few weeks; but the husbandmen left to cultivate the earth consisted of the infirm, aged, and decrepid; so that a famine was threatened in consequence of the military rage which had seized all the youth of the kingdom.

The king is unable to retrieve the Swedish affairs. A. D. 1715.

The presence of Charles did not now produce those consequences which the allies had feared. The kingdom was too much reduced to furnish the necessary supplies of men and money; and though the king's courage and military skill were not in the least diminished, the efforts which he made, instead of restoring Sweden to its splendour, served more completely to ruin it. In 1715, Prussia declared against him, on account of his demanding back the town of Stettin, which that monarch had seized. To complete his embarrassment, the elector of Hanover, George I. of Britain, also became his enemy. The forces of Denmark, Prussia, Saxony, and Hanover joined to invest Wismar, while a body of 36,000 men formed the siege of Stralsund; and at the same time the czar, with a fleet of twenty large ships of war, and 150 transports, carrying 30,000 men, threw every part of the Swedish coast into the greatest consternation. The heroism of Charles could not prevail against so many enemies; yet he was still so much dreaded, that the prince of Anhalt, with 12,000 brave troops, did not think himself a match for this furious enemy when at the head of only 2000, till he had intrenched his army behind a ditch, defended by chevaux de frise. It appeared, indeed, that this precaution was not unnecessary; for in the night Charles with his men clambered up the ditch, and attacked the enemy in his usual manner. Numbers, however, at last prevailed, and Charles was obliged to retire, after having seen his favourite Grothusen, General Dardoff, and During, the companions of his exile, killed by his side, he himself being wounded in the breast.

Is encompassed on all sides by enemies.

His desperate valour.

Stralsund besieged,

This rash attempt was made in order to save Rugen, whence the town of Stralsund was supplied with provisions. The place was well fortified, and garrisoned with 9000 men, with Charles himself at their head; but nothing could resist the efforts of the enemy. By the 17th of December it was proposed to give the assault. The attack on the horn-work was desperate; the enemy was twice repulsed; but at last, by dint of numbers, effected a lodgment. The next day, Charles headed a sally, in which he dealt terrible destruction among the besiegers, but was at length overpowered and obliged to retreat into the town. At last his officers, apprehending that he must either fall into the hands of the enemy, or be buried in the ruins of the place, entreated him to retire. A retreat, however, was now almost as dangerous as to remain in the town, on account of the fleets of the enemy with which the sea was covered; and it is thought that this very circumstance induced the king to consent to it. Embarking in a small boat with sails and oars, he passed all the enemy's ships and batteries, and arrived safe at Ystedt in Schonen.

and taken, in spite of the utmost efforts of the king.

Charles invades Norway.

To revenge himself for these losses, Charles invaded Norway with an army of 25,000 men. The Danes were everywhere defeated and pursued with that vigour for which the king of Sweden was so remarkable; but strong reinforcements arriving from Denmark, and provisions failing, he was at last obliged to retire. Soon after this the Swedes lost Wismar; but when every thing seemed hopeless, Baron Goertz, the chief minister and favourite of Charles, contrived to make overtures for a treaty with the czar of Russia, by which the most formidable of all Charles's enemies was taken off. The minister found means to work on the inflexible temper of Charles, by representing to him that the cession of certain provinces to Peter would induce him to assist him in his projects of again dethroning Augustus, and of replacing James on the throne of Britain; which last scheme he had projected out of revenge for the elector of Hanover having seized on the duchies of Bremen and Verden. In consequence of the conferences between the czar and Goertz, the former engaged to send into Poland an army of 80,000 men, in order to dethrone that prince whom he had so long defended. He also engaged to furnish ships for transporting 30,000 Swedes to Germany, and 10,000 into Denmark. This treaty was not however ratified, and the death of Charles put a final stop to all the great prospects of Sweden.

A treaty with the czar of Muscovy projected.

Charles invades Norway.

The king had resolved on the conquest of Norway before he dethroned Augustus; and as no difficulties ever deterred him, he marched his army into that cold and barren country in the month of October, when the ground was covered with frost and snow. With 18,000 men he formed the siege of Fredrickshall, though the severity of the frost rendered it almost impossible to break ground. He resolved to form trenches; and his soldiers cheerfully obeyed, digging into the ground with the same labour as if they had been piercing a rock. On the 11th of December the king visited the trenches in the midst of a terrible fire from the enemy, imagining that his men might be animated by his presence. He took his post in the most dangerous station that he could select, standing on a gabion and leaning with his arm over the parapet, while the enemy were firing chain shot at the very spot where he stood. He was entreated to

His death.

change his station, but he remained obstinate. At last he was seen to fall on the parapet, and was heard to utter a deep groan. He soon afterwards expired, having been mortally wounded, as is supposed, by a cannon-ball.

Account of the Swedish affairs from the death of Charles XII. to the year 1771.

Charles XII. was succeeded by his sister the princess Ulrica Eleonora, wife to the hereditary prince of Hesse. On this occasion the states took care to make a previous stipulation for the preservation of their liberties, and obliged the princess, before entering on the government, to sign a document to this effect. Their first care was to make peace with Great Britain, which the late king intended to have invaded. In order to prevent their further losses by the progress of the Russian, the Danish, the Saxon, and other arms, the Swedes made many great sacrifices to obtain peace from these powers. The French, however, about the year 1738, formed a dangerous party in the kingdom, which not only broke its internal quiet, but led it into a ruinous war with Russia, by which it lost the province of Finland. Their Swedish majesties having no children, it was necessary to settle the succession; especially as the duke of Holstein was descended from the queen's eldest sister, and was, at the same time, the presumptive heir to the empire of Russia. Four competitors appeared; the duke of Holstein Gottorp, Prince Frederic of Hesse-Cassel, nephew to the king, the prince of Denmark, and the duke of Deux-Ponts. The duke of Holstein would have carried the election, had he not embraced the Greek religion that he might mount the throne of Russia. The czarina interposed, and offered to restore all the conquests she had made from Sweden, excepting a small district in Finland, if the Swedes would receive the duke of Holstein's uncle, Adolphus Frederic, bishop of Lübeck, as their hereditary prince and the successor to the crown. This was agreed to; and a peace concluded at Abo, under the mediation of his Britannic majesty. The peace was so firmly maintained by the empress of Russia, that his Danish majesty thought proper to drop all resentment for the indignity offered his son. The prince-successor married the princess Ulrica, third sister to the king of Prussia; and in 1751 he entered into the possession of his new dignity, which proved to him a crown of thorns. The French had acquired great influence in all the deliberations of the Swedish senate, who of late had been little better than pensioners to that crown. The intrigues of the senators forced Adolphus to take part in the war against Prussia; but as that war was disagreeable, not only to the people, but also to the king of Sweden, the nation never made so mean an appearance; and on Russia's making peace with the king of Prussia, the Swedes followed the example. Adolphus died dispirited in 1771, after a turbulent reign of twenty years, and was succeeded by his son Gustavus.

Accession of Adolphus Frederick. A. D. 1751.

Gustavus III. ascends the throne. A. D. 1771.

The most remarkable transaction of this reign is the revolution which took place in the government in the year 1772, by which the king, from being the most limited, became one of the most despotic monarchs in Europe. Ever since the death of Charles XII. the whole power of the kingdom had been lodged in the states; and this power they had much abused. Gustavus therefore determined either to seize on that power of which they made such a bad use, or to perish in the attempt. The revolution was effected in the following manner. On the morning of the 19th of August 1772, a considerable number of officers, as well as other persons known to be attached to the royal cause, had been summoned to attend his majesty. Before ten he was on horseback, and visited the regiment of artillery. As he passed through the streets he was more than usually courteous to all he met, bowing familiarly to the lowest of the people. On the king's return to his palace, the detachment which was to mount guard that day being drawn up together with that which was to be relieved, his majesty retired with the officers into the guard-room. He then addressed them with all that eloquence of which he is said to have been a master; and after insinuating to them that his life was in danger, he exposed to them in the strongest colours the wretched state of the kingdom, the shackles in which it was held by means of foreign gold, and the dissensions and troubles arising from the same cause which had distracted the diet during the course of fourteen months. He assured them that his only design was to put an end to these disorders, to banish corruption, restore true liberty, and revive the ancient lustre of the Swedish name, which had been long tarnished by a venality as notorious as it was disgraceful. Then assuring them in the strongest terms that he disclaimed for ever all absolute power, or what the Swedes call *sovereignty*, he concluded with these words: "I am obliged to defend my own liberty and that of the kingdom against the aristocracy, which reigns. Will you be faithful to me, as your forefathers were to Gustavus Vasa and Gustavus Adolphus? I will then risk my life for your welfare and that of my country." The officers, most of them young men, of whose attachment the king had been long secure, and who did not perhaps perceive the real tendency of his majesty's request, were allowed no time to reflect, immediately gave their assent, and took an oath of fidelity to him. Only three refused. One of these, Frederic Cederström, captain of a company of the guards, alleged he had already, and very lately, taken an oath to be faithful to the states, and consequently could not take that which his majesty then exacted. The king, looking at him sternly, answered, "Think of what you are doing." "I do," replied Cederström; "and what I think to-day I shall think to-morrow; and were I capable of breaking the oath by which I am already bound to the states, I should be likewise capable of breaking that which your majesty now requires me to take." The king having then ordered Cederström to deliver up his sword, placed him under arrest. His majesty, however, apprehensive of the impression which his proper and resolute conduct might make on the minds of the other officers, soon afterwards softened his tone; and again addressing himself to Cederström, told him, that as a proof of the opinion which he entertained of him, and the confidence which he placed in him, he would return him his sword without insisting on his taking the oath, and would only desire his attendance that day. The undaunted captain continued firm; he answered, that his majesty could place no confidence in him, and that he begged to be excused from the service.

Account of the revolution in 1772, by which he became despotic.

Resolutio of a Swedish offic

While Gustavus was shut up with the officers, senator Ralling, to whom the command of the troops in the town had been given two days before, came to the door of the guard-room, and was told that he could not be admitted. The senator insisted on being present at the distribution of the orders, and sent to the king to desire it; but was answered, he must go to the senate, where his majesty would speak to him. The officers then received their orders from the king; the first of which was, that the two regiments of guards and of artillery should be immediately assembled, and that a detachment of thirty-six grenadiers should be posted at the door of the council-chamber to prevent any of the senators from coming out. But before the orders could be carried into execution, it was necessary that Gustavus should address himself to the soldiers; men wholly unacquainted with his designs, and accustomed to pay obedience only to the orders of the senate, whom they had been taught to hold in the highest reverence. As his majesty, followed by the officers, was advancing from the guard-room to the parade for this purpose, some of them, more cautious, or perhaps more timid, than the rest, became, on a short reflection, apprehensive of the consequences of the measure in which they were engaged: they began to express their fears to the king, that unless some person of greater weight and influence than themselves

The king gains over the soldiers.

were to take a part in the same cause, he could scarcely hope to succeed in his enterprise. The king stopped a while, and appeared to hesitate. A serjeant of the guards overheard their discourse, and cried aloud, "It shall succeed. Long live Gustavus!" His majesty immediately said, "Then I will venture;" and stepping forward to the soldiers, he addressed them in terms nearly similar to those which he had employed to the officers, and with the same success. They answered him with loud acclamations. One voice only said, No; but it excited no attention.

Secures the senators, and becomes master of the whole power in the kingdom.

In the mean time some of the king's emissaries had spread a report about the town that his majesty was arrested. This drew the populace to the palace in great numbers, where they arrived as he had concluded his harangue to the guards. They testified by reiterated shouts their joy at seeing him safe; a joy which promised the happiest conclusion to the business of the day. The senators were now immediately secured. They had from the window of the council-chamber beheld what was going forward on the parade before the palace; and, at a loss to know the meaning of the shouts which they heard, were coming down to inquire into the cause of them, when thirty grenadiers, with their bayonets fixed, informed them it was his majesty's pleasure they should continue where they were. They began to speak in a high tone, but were only answered by having the door shut and locked upon them. The moment the secret committee heard that the senate was arrested, they separated of themselves, each individual providing for his own safety. The king then mounting his horse, followed by his officers with their swords drawn, a large body of soldiers, and numbers of the populace, went to the other quarters of the town where the soldiers whom he had ordered to be assembled were posted. He found them all equally willing to support his cause, and to take to him an oath of fidelity. As he passed through the streets, he declared to the people, that he only meant to defend them, and save his country; and that if they would not confide in him, he would lay down his sceptre, and surrender up his kingdom. So much was the king beloved, that some of the people even fell on their knees, and many more, with tears in their eyes, implored his majesty not to abandon them.

Summons an assembly of the states;

which accepts a new form of government.

The king proceeded in his course, and in less than an hour made himself master of all the military force in Stockholm. In the mean time the heralds, by proclamation in the several quarters of the city, summoned an assembly of the states for the ensuing morning, and declared all members traitors to their country who should not appear. Thither his majesty repaired in all the pomp of royalty, surrounded by his guards, and holding in his hand the silver sceptre of Gustavus Adolphus. In a very forcible speech, he lamented the unhappy state to which the country was reduced by the conduct of a party ready to sacrifice every thing to its ambition, and reproached the states with adapting their actions to the views of foreign courts, from which they received the wages of perfidy. "If any one dare contradict this, let him rise and speak." Conviction, or fear, kept the assembly silent, and the secretary read the new form of government, which the king submitted to the approbation of the states. It consisted of fifty-seven articles; of which the five following were the chief. 1. The king has the entire power of convoking and dissolving the assembly of the states as often as he thinks proper. 2. His majesty alone has the command of the army, fleet, and finances, and the disposal of all offices civil and military. 3. In case of an invasion, or of any pressing necessity, the king may impose taxes, without waiting for the assembly of the states. 4. The diet can deliberate on no other subjects than those proposed by the king. 5. The king shall not carry on an offensive war without the consent of the states. When all the articles were recited, the king demanded if the states approved of them, and was answered by a general acclamation. He then dismissed all the senators from their employments, adding, that in a few days he would appoint others; and concluded this extraordinary scene by drawing out of his pocket a small psalm-book, from which, after taking off the crown, he gave out *Te Deum*. All the members very devoutly added their voices to his, and the hall resounded with thanksgiving.

The king makes a good use of his power.

The power which he had thus obtained, he employed for the good of his subjects. He took care that the law should be administered with impartiality to the richest noble and the poorest peasant, making a severe example of such judges as were proved to have made justice venal. He gave particular attention and encouragement to commerce; and being himself a man of letters, was a liberal and enlightened patron of literature and science. He strenuously laboured to introduce into his kingdom the most valuable improvements in agriculture that had been made in foreign countries.

Reforms the army and navy.

But while thus active in promoting the arts of peace, he was not inattentive to the art of war. The fleet, which he found decayed and feeble, he in a few years restored to a respectable footing; and, besides changing the regulations of the navy, he raised a new corps of sailors, and formed them to the service by continual exercise. The army, which, like the navy, had been neglected during the aristocracy, was next to be reformed. The king began by giving cloaks, tents, and new arms to all the regiments. Afterwards, under the direction of Field-marshal Count de Hessenstein, a new exercise was introduced, and several camps were formed, in which the soldiery were manœuvred by the king himself. The sale of military offices, which had been permitted for many years, was entirely suppressed; and the king provided not only for the re-establishment of discipline and good order in the army, but for the future welfare of the individuals who composed it. These warlike preparations were necessary to a plan which he had formed for entirely abolishing the power of the aristocracy, and freeing Sweden from the factions which had long been formed in it by the court of St Petersburg. The change which he had introduced was very inimical to the intrigues of that court; and the Russian ambassador exerted himself openly to bring about a rupture between the king and the discontented nobles. Gustavus ordered him to quit the kingdom in eight days, and immediately prepared for war with Russia. To this apparently rash enterprise he was incited by the Ottoman Porte, at that time unable to oppose the armies of the two empires; and his own ambition, together with the internal state of his kingdom, powerfully concurred to make him lend every assistance to his ancient ally. It is needless for us to enter into a detail of the particulars of that war, the principal circumstances of which have already been noticed under Russia. Suffice it to say, that neither Gustavus Adolphus nor Charles XII. gave greater proofs of undaunted courage and military conduct in their long and bloody wars than were given by Gustavus III. from the end of the year 1787 to 1790, when peace was restored between the courts of St Petersburg and Stockholm. When the court of Copenhagen was compelled, by the means of England and Prussia, to withdraw its troops from the territories of Sweden, the king attacked Russia with such vigour both by sea and land, displayed such address in retrieving his affairs when apparently reduced to the last extremity, and renewed his attacks with such pertinacious courage, that the empress lowered the haughtiness of her tone, and was glad to treat with Gustavus as an equal and independent sovereign.

His conduct in the war with Russia.

A conspiracy formed against the king's life.
A. D. 1792.

Sweden now enjoyed peace; but the nobles continued discontented, and a conspiracy was planned against Gustavus under his own roof. He had entered into the alliance that was formed against the revolutionary government of France; and in order to raise an army, which he was to

The king dangerously wounded.

Death of Gustavus III. A. D. 1792.

lead in person, to co-operate with the emperor and the king of Prussia, he was obliged to negociate large loans, and to impose on his subjects heavy taxes. The nobles took advantage of that circumstance to prejudice the minds of many of the people against the sovereign who had laboured so long for their good. On the 16th of March 1792 he received an anonymous letter, warning him of his immediate danger from a plot that was laid to take away his life; requesting him to remain at home, and avoid balls for a year; and assuring him that, if he should go to the masquerade for which he was preparing, he would be assassinated that very night. The king read the note with contempt, and at a late hour entered the ball-room. After some time, he sat down in a box with Count d'Essen, and observed that he was not deceived in his contempt for the letter, since, had there been any design against his life, no time could be more favourable than that moment. He then mingled, without apprehension, among the crowd; and just as he was preparing to retire in company with the Prussian ambassador, he was surrounded by several persons in masks, one of whom fired a pistol at the back of the king, and lodged the contents in his body. A scene of dreadful confusion immediately ensued. The conspirators, amidst the general tumult and alarm, had time to retire to other parts of the room; but one of them had previously dropped his pistols and a dagger close by the wounded king. A general order was given to all the company to unmask, and the doors were immediately closed; but no person appeared with any particular distinguishing marks of guilt. The king was immediately conveyed to his apartment; and the surgeon, after extracting a ball and some slugs, gave favourable hopes of his recovery. But the prognostication of his medical attendants soon appeared to be fallacious, and on the 28th of March a mortification was found to have taken place. He expired on the following day; and on opening his body there were found within the ribs a square piece of lead and two rusty nails.

The king had by his will appointed a council of regency; but convinced by recent experience how little dependence was to be placed on the attachment of his nobles, and aware of the necessity of a vigorous government in times of such difficulty and danger, he appointed his brother, the duke of Sudermania, sole regent, till his son, then a minor, should attain the age of eighteen years. In his dying moments he desired that all the conspirators, except the perpetrator of his murder, might be pardoned.

Accession of Gustavus IV.

The young king, who was about fourteen at his father's death, was proclaimed by the name of Gustavus IV. The regent soon took the most vigorous and active measures to apprehend and punish the projectors and perpetrators of the murder of his brother. A nobleman of the name of Ankarström confessed himself the assassin, and gloried in the action, which he called liberating his country from a monster and a tyrant. He was executed in a most cruel manner on the 17th of May. Other two noblemen, and two officers, also suffered death; but the rest of the conspirators were either pardoned, or punished only by fine and imprisonment.

From the accession of Gustavus IV. till the revolution which has been recently effected in Sweden, few transactions of any importance have occurred. Soon after the king had assumed the administration of affairs, he engaged warmly in the war against France, and till the time of his deposition continued a most faithful ally of Britain. The efforts of the Swedish monarch towards humbling the power of Bonaparte have been already noticed under the articles BRITAIN and FRANCE; and the war with Russia, in which his alliance with Britain had involved him, has been sufficiently touched in the article RUSSIA. This prince seems to have been endowed with amiable qualities; but he was certainly rash and imprudent, and perhaps in some degree tinctured with insanity. He thus materially injured his kingdom, and alienated the affections of his principal nobles, especially of his uncle the duke of Sudermania.

Revoluti
in favour
the duke
Suderma
nia.
A. D. 18

In the beginning of March 1809, the plan which appears to have been concerted between the duke of Sudermania and the principal nobility was carried into effect. The king was arrested; the duke assumed the reins of government, and issued a proclamation, announcing that, under existing circumstances, the king was incapable of conducting the affairs of the nation. Gustavus, now in close custody, was easily prevailed upon to abdicate the government. The diet was assembled; the duke of Sudermania was declared king of Sweden, under the title of Charles XIII.; Prince Augustenberg was chosen crown prince; and various changes were introduced into the constitution, confirming the powers of the diet, and removing what the prevailing party held to be encroachments of the crown during the late and preceding reigns. The people, wearied or disgusted by the late king's folly and rashness, readily acquiesced in all the alterations. Peace was then made with Russia; a measure which had become absolutely necessary, as the military force of the kingdom was completely broken, and no means were left for checking the progress of the enemy. By this peace Sweden lost Finland, a country of peculiar importance to her, on account of the supplies of grain which she was accustomed to draw from it; but in the treaty she reserved the right of yearly importing a certain quantity of grain, duty free. Swedish Finland, with Lapmark, now annexed to Russia, was estimated to contain about 120,000 square English miles, with 895,000 inhabitants. On the 6th of January 1810, peace was also concluded with France, which restored Pomerania.

Sweden was now enjoying tranquillity, when the sudden and unexpected death of the crown prince Augustenberg, in April 1810, became a new source of perplexity. The duke of Sudermania was old and in a feeble state of health; and as there was no person within the kingdom who had any title by blood to the throne, it was necessary, for the security of the new order of things, to choose a successor. The threatening position which the acquisition of Finland gave to Russia induced the noblemen who in concert with the court took a lead in this business, to look for some man of military talents. It happened that Bernadotte, prince of Ponte Corvo, who had lately commanded in the north of Germany, had, by his liberal and kind treatment, gained the peculiar esteem of the Swedish officers and soldiers whom he had made prisoners in Gustavus's ill-concerted operations in Pomerania. He was besides highly respected for his military skill; and had been still further raised in general estimation, in consequence of Napoleon having removed him from his command for his lenity and humanity in the exercise of his power. Some of the Swedish officers, to whom his character was known, first conceived the idea of offering him the succession to the crown. The scheme was for some time kept as secret as possible; but it received so much countenance from the most considerable men, that it was at length opened to Bernadotte himself at Paris. He received it as might be expected, and his friends redoubled their intrigues. The prince of Denmark had been proposed, but the ancient enmity against that country was an invincible obstacle to his success. At length, when every thing was prepared, the diet was called, and Bernadotte was with acclamation elected crown prince by all the four orders, on the 21st of July. Of all the changes in the fortune and station of individuals which arose out of the French revolution, this is perhaps the most singular. Bonaparte seized the royal power and dignity for himself, and by force of arms he compelled some of the weaker states to accept his relations and followers as kings. But it does not appear that he was ever consulted as to Bernadotte's elevation, or had the smallest influence in it, except that the example given in his own person and that of his followers had contributed to destroy some of the old illusions as to birth and hereditary honours, and had prepared men's minds for great innovations. It was thus that the son of a French peasant, who began his career as a common soldier, was raised to the Swedish throne by the spontaneous choice of a body of nobles, proud of their birth and ancestry.

The appearance of Bernadotte in the Swedish capital was followed by numerous feasts and spectacles. He received congratulations from all the public bodies; and though not immediately called to the throne, was, from the king's infirmities, intrusted with the entire conduct of the government. One of his first acts was to recommend to the diet the introduction of a conscription law like that of France, a measure which certainly hazarded his popularity. It was however adopted; and on this occasion he prevailed with the nobles to make a voluntary surrender of their ancient privilege of exemption from military service, as well as from taxation. Pressed by France and Russia, Sweden, in November 1810, professed her adherence to the continental system, and declared war against Britain. The war however was only nominal, and the British cruisers returned in most cases their captures untouched. This state of things continued till Bonaparte was preparing for his great Russian campaign, when the Swedish government, solicited by both parties, and tempted by great offers, at length signed treaties of alliance with Russia and Britain in 1812 and 1813. By these treaties, the two powers mentioned engaged to assist the king in conquering Norway from Denmark. The French, for the purpose of intimidation, had previously seized Pomerania. Bernadotte carried over an army of 30,000 Swedes to Germany in 1813; and being joined by several large bodies of Prussian and German troops, he was encountered by Marshal Ney between Berlin and Leipzig on the 6th September, and, after an obstinate engagement, drove back the French army with the loss of 16,000 men. In the battle of Leipzig, fought on the 18th October, he likewise bore a conspicuous share. After the victory, he continued to act against Marshal Davoust's corps, and against the Danes, till he reduced the latter to the necessity of capitulating. He lost no time in improving this advantage; and by a treaty concluded at Kiel on the 14th January 1814, compelled Denmark to cede Norway, on surrendering to her the possession of Pomerania, and thus securing a great advantage by the exchange of territory. He now advanced to the Rhine; but, satisfied with reducing Napoleon's power, and, from views of interest, most probably adverse to ruining him, he was thought to be rather dilatory in improving his advantages. The success of the allies at length left him at liberty to secure Norway, the prize for which he had fought. As the Norwegians announced their intention of resisting, he crossed the frontier with an army in July, and, by judicious manœuvres, which placed the Norwegian force in his power, he obliged them to capitulate, and obtained possession of the country almost without bloodshed; Norway preserving its ancient constitution, and having states of its own. On the death of Charles XIII. in 1818, Bernadotte mounted the throne; and being still on good terms with most of the surrounding powers, has every chance to preserve his situation, and transmit the crown to his posterity.

STATISTICS.

Sweden and Norway form together one geographical region, situated between 4° and 32° E. Long., and 55° and 71° N. Lat. The greatest length, from Falsterbo in the province of Malmo, to Cape Nordkun in Finmark, exceeds 1000 geographical miles, and the superficial area is about 292,700 English square miles, of which 170,150 are in Sweden. Throughout the length of the peninsula, from the Varangerfiord in the north-east to the Scagerack in the south-west, a line of lofty and rugged mountains, hills, and table-lands extends for 1110 miles, forming the water-shed between the shores of the ocean and the basin of the Baltic Sea. Numerous rivers, which have their source at the base of this range, empty themselves into the Gulf of Bothnia. The principal of these are the Tornea, which, with its affluent the Muonio, forms the boundary between Swedish and Russian Lapmark; the Kalix, the Ranea, the Lulea, the Pitea, the Sildut or Skellestia, the Unea, and Windel; the Gildea, the Angerman, the Indals, the Ljusne, and Dahl. The Gotha is the outlet of Lake Wenner, and runs into the Cattegat at Gottenburg.

The lakes of Sweden are numerous, and cover a large space of the surface of the country. The principal of these are the Wenner, which, after those of Ladoga and Onega, is the largest in Europe; it is ninety miles in length by thirty-six at its greatest breadth, and covers an area of 2136 square miles. The Wetter measures eighty-two miles in length by sixteen at its greatest breadth; but is generally much narrower, and only contains 830 square miles. The Malar extends from Stockholm, nearly seventy miles in length; it is crowded with islands, and presents throughout the greatest variety of beautiful scenery. At Stockholm it communicates, by a narrow strait, with an arm of the Baltic Sea, forming a very intricate navigation of sixty miles between the open sea and the capital.

Soil and vegetation.

Sweden is not more fortunate in its soil than in its climate. It cannot boast of any of those deep rich alluvial deposits which elsewhere usually occupy a large portion of low and well-watered countries. Coarse sand or gravel, but partially covered over with a thin layer of fertile soil, forms in general the champaign country; and, besides the woods, which occupy more than three fourths of its surface, a large portion is covered with lakes, morasses, rivers, and with inconceivable numbers of boulder-stones or isolated rocks of every size. The surface has been thus numerically represented in square miles: Woods, 137,420; lakes, marshes, &c., 11,900; meadows, pastures, &c., 7350; arable land, 3480; total, 170,150 square miles. The soil of Norway is of much the same character as that of Sweden, in both the vegetation being abridged by the length and the severity of the winter: the soil remains always poor; and the paucity of alluvial tracts, with the prevalence of rock, seldom far beneath, and often forming the surface, materially detract from the quality as well as the quantity of the soil. In some parts however it is very rich, and the valleys in particular are celebrated for their luxuriant fertility; but even there much of the soil is thin, and obstructed by rocky knobs rising above its surface.

Climate.

In the most favoured situations of Sweden, as at Lund in Schonen, the mean temperature of the year does not exceed 45° Fahr., while at the North Cape it is at the freezing point; the extreme cold, however, is modified by the elevations of the land, and its proximity to the sea. At North Cape, lat. 70° N., potatoes, broccoli, and gooseberries, are raised with some difficulty; one degree farther south a little barley makes its appearance. In lat. 68° 20′, at Enontekeis, the crops of barley yield a remunerating harvest once in the three years. Rye and hemp cannot be successfully cultivated beyond 66°, nor oats beyond 64°; this latter is also the general limit of garden cultivation. The cherry-tree, alder, and maple cease to thrive beyond 63°; the ash and willow beyond 62°; the elm, lime, and oak beyond 61°; and the natural beech-woods do not extend beyond 57°. The mulberry, the chestnut, and the walnut arrive at perfection in Schonen, 54°. In the southern parts of the country an elevation of 500 feet above the level of the sea is found to have the same effect on the climate and vegetation as 175 miles of north latitude, a thousand feet as 300 miles, and two thousand feet as 630 miles; but the effect is of course more rapid and powerful as we advance to the north.

People. The inhabitants consist of Swedes, Lapons or Laps, and Finns. The Swedes are a branch of the same family as the Danes and Norwegians, and speak a dialect of the same language, considerably modified, however, by the consequences of the long political separation and international enmity of the two nations. Books are translated from the one language to the other; but the vulgar tongue, the language of the peasantry in Sweden and Norway, differs not much more than broad Scotch from Cockney English. The roots of words, construction, and idioms are the same in both, or have a common origin.

Population. In 1751 the population of Sweden amounted to 1,785,727, in 1800 to 2,347,303, and in 1830 to 2,888,082. Norway in 1825 contained 1,051,318 inhabitants, and in 1836 the population was 1,200,000, showing an increase of nearly 150,000 during the preceding ten years. In Sweden the annual number of births is one to twenty-eight of the population, in Norway one to thirty-four. In Sweden the marriages are one in 112, in Norway one in 130; but in Sweden the mortality is one in thirty-four and a half, and in Norway only one in forty-eight. The standing army amounts to 33,000; but in the time of war it may be raised by conscription to 240,000. In 1825 the inhabitants of the towns of Sweden amounted to 279,645, or about one tenth of the population. Stockholm had then a population of 97,183, Gottenburg 26,702, Carlscrona 11,943. All the other towns are little better than villages.

The Swedes are represented to be a brave, hardy, generous, and enterprising people, distinguished by a happy union of courage and steadiness, fine genius, and natural probity of disposition. They are said, however, to be greatly addicted to drunkenness; and this unfortunate habit is the fruitful source of many evils, both moral and physical.[1] In 1835 one person out of every 114 of the population was accused, and one out of every 140 convicted, of some criminal offence.

Religion. With the exception of a few congregations in Stockholm and other principal towns, the Swedes are all Lutherans, and Lutheranism is the established religion of the state. Other sects are now allowed the free exercise of worship; but Catholics and all other dissenters are excluded from the diet and higher offices of state. In the whole kingdom there are 2490 congregations, viz., 1147 country parishes, and 129 town charges, with 1214 annexed chapels in the larger parishes. The whole personal establishment consists of 3193 clergy, and 3753 sextons or parish-clerks, organists, and church servants. The hierarchy consists of one archbishop of Upsala, and eleven bishops, viz. of Lund, Gottenburg, Wexio, Calmar, Linkioping, Skara, Carlstadt, Wisby, Westeraas, Strangnæs, and Hernosand; seventy archdeacons, and 192 probsts (provosts or deans). The archbishop's income is rated at about L.2000 sterling a year, the bishops at more than L.600 each, and the archdeacons and probsts from L.400 to L.700 each. None of the inferior clergy has less than L.120, while many have as much as L.300, besides parsonage-houses and glebe-lands. The clergy, as a body, have been always distinguished for piety and morality, and yet among their people religious feeling and moral purity are at a very low ebb; their religion indeed has become little better than a system of rites and ceremonies. There is, however, a spirit of religious enthusiasm spreading in the north of Sweden, especially among the new colonists or squatters in Lapland; but this spirit the clergy attempt to extinguish. These religionists are called Læseren, or readers, from their reading the scriptures; but they do not form a sect having internal communion and regulations. They are however numerous; their numbers are said to be increasing, and their meetings for preaching are attended by people from great distances. The Catholics throughout the kingdom do not amount to 2000, the greater part of whom reside in the capital, and the whole are foreigners. The Swedenborgians, the only sect which the country has produced, are also comparatively few. The Jews scarcely exceed 1000 individuals, and have four synagogues, at Stockholm, Gottenburg, Norrkoping, and Carlscrona.

Educatio Of the whole population, including even the Laps, it is reckoned that the proportion of grown persons unable to read is less than one in a thousand. This general diffusion of elementary education is ascribed to the zeal of King Gustaf-Wasa (Gustavus Vasa, 1523-1560), and his immediate successors. John III., in 1574, ordered that the nobleman who had no knowledge of book-learning should forfeit his nobility; Charles XI., in 1684, required the clergy to have every Swedish subject taught to read; and made it a law that no marriage should be celebrated unless the parties had previously taken the Lord's Supper; and that none should be admitted to the communion-table who could not read, and was not instructed in religion. Parish schools, however, are only found where there happen to have been lands or rents bequeathed for their endowment; and these in some parishes are ambulatory, in others fixed. It is supposed that more than half of all the parishes have no schools; but the deficiency is supplied by the people themselves, who teach their children at home in the leisure hours of their long winters. The king, however, in his speech at the opening of the present diet, 1840, has recommended the establishment of a primary school in every parish. In the provincial towns there are gymnasia, or high schools, which prepare youth for the universities. They are under the care of the bishops, and, besides the higher branches of Greek and Roman literature, their course often embraces the oriental languages, and the leading doctrines of theology. There are two universities, one at Upsala, and the other at Lund. In these the teachers may be divided into three classes: 1. professors; 2. adjuncts, or privileged teachers in different sciences, who give instruction privately or publicly to the students, and who are expectants of professorships; and 3. the masters in modern languages, exercises, and other inferior branches. Of the theological faculty there are four professors at Upsala, and four at Lund; of the juridical faculty, two at each; of the medical and surgical, five at each; of the philosophical and literary, fourteen at Upsala, and ten at Lund.

Government. The constitution is of a mixed character, in which the executive and administrative departments are managed by a hereditary king and his ministers, while the legislative is vested conjointly in the king and a diet of four chambers, elected by the nobles, clergy, burghers, and peasants. The noble families are reckoned at about 2400. The head of each is by right a member of the diet, but seldom more than 400 take any part in its proceedings. The clergy have sixty representatives, including the archbishop and bishops, of whom the primate is always president. The burghers are elected by eighty-five cities and towns; Stockholm returning ten, Gottenburg three, Norrkoping two, and each of the rest one. The peasantry have between 140 and 150 representatives, chosen by districts; and these, as well as the burghers, are required to possess a certain amount of qualification in property; and each of their chambers has a president, appointed by the king. During the session each member of the last three orders receives a small pecuniary compensation, paid by his constituents, the amount of which is voluntary. The diet meets at intervals of five years, and then sits for three months certain, but generally longer. Practically, the power of the diet rests in the nobility and clergy. But the most important branch of the constitution is the council of state, which consists of one minister for justice, one for foreign affairs, other six councillors, and the chancellor of the court, and is attended by the four secretaries of state, who have the four departments of home affairs; military and naval affairs; finances, trade, customs, and post-office; and affairs of the church, general education, and the poor. The king can do nothing, except in military and diplomatic affairs, without consulting this council, which must keep a protocol of its proceedings, in which each member has a right to explain his opinions.

---

[1] Laing's Travels in Sweden, p. 110.

Finances.

Relatively to its means, Sweden is much more heavily taxed than either England or France, and yet the public revenues raised by taxation do not amount to L.2,000,000 sterling. According to the report of 1832, the sum was 20,247,339 dollars banca, or L.1,687,278 sterling, of which more than one half was raised by a direct land-tax, the remainder by customs and other indirect means.

Productive industry.

Since the beginning of the present century, the agriculture of Sweden has experienced great improvement. The Swedes have become exporters of grain to a considerable extent; and as seven ninths of the population are engaged in the cultivation of the soil, a large proportion of which is still unproductive from want of cultivation, the quantity might be very greatly increased. The whole annual produce of the soil is estimated at forty-five millions of dollars. Within a few years land has risen considerably in value; and this is owing to the exertions of the agricultural societies established in the provinces, and the great interest which the landed proprietors now take in the management and improvement of their estates. The cultivation of the potato has indeed been the mainspring in the improvement of Swedish agriculture. Not only has it precluded the necessity of using the bark of trees as a miserable substitute for bread, but has occasioned the public and private magazines to be completely filled with grain; and the greatest difficulty with which cultivators have at present to contend, is the want of a market for their surplus stock.

Both horses and horned cattle are small in Sweden. The former, however, are active and spirited, the latter afford excellent milk and beef. The sheep are generally of an inferior kind; but great pains have been taken to improve them by crosses with the Spanish, French, and English breeds. Towards the sixty-third degree, sheep disappear, and are superseded by goats, which are most numerous in the woodland districts of Dalarne and Nordland. The seed-time is in May, the harvest in August, and as the fine weather is short and warm, the labours of the farmer are then very constant and fatiguing, while a great number of people are required to reap the crops, for whom there is no employment during winter, when the country is all covered with snow. This will ever remain an obstacle to agricultural improvement, especially in the northern districts. The average of the harvests throughout the kingdom for seven years has been found to be three good, three middling, and one a failure. The average rate of fecundity is four and three seventh grains for one.

Fisheries.

Both the sea and the fresh waters swarm with fish, which afford employment and subsistence to many of the inhabitants. The fresh waters contain perch, pike, salmon, trout, grayling, char, roach, bleak, and eels; but of all these the salmon is the most important object of industry and trade. They are more abundant in the northern rivers than in those of the south, and fisheries are established on most of them. The sea-fish are not less numerous or important. Herrings are sometimes caught in incredible numbers at Gottenburg, though at other times they entirely forsake the coast.

Mines and minerals.

Next to agriculture, the mines of Sweden are the chief source of her wealth. Throughout the kingdom, iron exists in great abundance. The mountain Gellivara, in Lapmark, 1800 feet high, is one mass of the richest iron ore; but its situation beyond the polar circle (in lat. 67° 20′ N.), far from the sea, and in an unpeopled wilderness, deprives it of its value. In various other places, however, there are similar hills, and even islands of compact iron ore are to be found near the coast. About the year 1683, the quantity of iron forged in Sweden in one year amounted to 9690 tons, but in the course of the next century a great increase took place. Between the years 1759–60, the average annual produce amounted to 328,766 Swedish pounds, and has continued very nearly the same to the present time, though it is represented as being now in a state of great activity and prosperity. The quantity of bar-iron produced in the year ending 1st November 1839 is stated at 276,000 skip pounds, and of manufactured iron 33,600, which, added to 11,600 of the latter, and 126,700 of the former, on hand at 1st November 1838, made a total of 448,000 skip pounds. Of this amount, 304,896 were exported, 283,500 in the shape of bar, and 21,390 manufactured; the prices during the year having been ten bank rix-dollars, or L.1. 5s. 10d. sterling the skip pound, which is equal to 280 pounds, or a quarter of a ton avoirdupois. The forests of Sweden occupy more than one half of its surface; and the abundance of wood thus supplied is of the highest utility in working the mines and smelting the ores. Swedish iron is superior in ductility and malleability to all others; a superiority which is attributed in part to the use of wood instead of coal or peat in their furnaces. The number of mines in all Sweden is 586; and of these no fewer than 361 are close together in the heart of the kingdom, in Nerike, Westmanland, and part of Dalarne. Danemora, the principal iron mine, produces yearly about 4000 tons of metal, which is particularly adapted to the manufacture of steel. Next to iron, copper forms the most important of the mineral riches of Sweden. The principal mine has long been at Fahlun, but the produce scarcely exceeds 1,000,000 pounds. The most important of the other copper-mines are those of Hakanbo in Nerike, Nyakopparberg in Nykopingslan, Atvedaberg in Linkopingslan, at Areskuta in Jemtland, and Ryddarshytta and Bastras in Westeraaslan. The whole copper produced in Sweden in 1824 was 814 tons, of the value of L.51,777 sterling. Gold is also found at Fahlun and in some other places; but the produce is too small to pay the expense. Silver is also produced to the extent of about 3000 marks annually; but the expense is so great that it is proposed to relinquish the working. Fahlun likewise produces sulphur and vitriol. In Scania, near Helsingfors, there is a small bed of coal; and cobalt, to the value of about L.12,000 sterling, is also produced in Sweden.

Manufactures.

The manufactures are in a very low state. Every art and trade has its own corporate rights and monopolies, which operate as a complete bar to improvement; and of the total population only about one-seventieth part is engaged in manufactures and trade of every kind. Coarse linens are the chief manufacture. Machinery for spinning wool and cotton has been introduced, but the experiment is too recent to warrant a decided opinion as to its ultimate success. The other articles of manufacture are such common goods as are required to supply the ordinary wants of the people.

Commerce.

The general trade of Sweden is in almost as low a state as its manufactures. The principal exports consist of articles of native produce, in their raw or manufactured state. Iron ranks first, then timber, copper, tar, and grain. The principal imports are sugar, coffee, tobacco, salt or smoked fish, salt, leather, hemp, silk, cotton, and wine, chiefly articles of domestic comfort or luxury. Mr Laing states the amount of the mercantile shipping at only 30,439 tons; but Forsell states it as having been, Swedenborg.

in 1831, 137,514 tons, or 1122 vessels. The principal mercantile ports are Stockholm and Gottenburg.

Administrative divisions.

Sweden is divided into twenty-four *lans*, or governments, which are subdivided into *fogderier*, or districts. Swedish geographers, however, divide the country into three large regions, namely, *Norrland*, or the north country; *Svealand*, or Sweden Proper; and *Gothaland*, or Gothia; each of these comprising several lans, as stated in the following table.

Sweden borg.

Governments.	Ancient Provinces.	Cities and Towns.
SVEALAND.		
Stockholm...	Upland and Sodermanland	Stockholm, Carlberg, Marieberg, Drotningholm, Nortelge, Sodertelge, Vaxholm.
Upsala..........	Upland......	Upsala, Sigtuna, Lofsta, Elfkarleby, Sodersfors, Dannemora.
Westeraas...	Westmanland.......	Westeraas, Sala, Norberg, Arboga, Koping.
Nykoping....	Sodermanland.......	Nykoping, Strengnass, Gripsholm, Eskilstuna.
Oerebro......	Nerike and Westmanland.......	Oerebro, Nora, Askersund.
Carlstad......	Warmeland	Carlstad, Christinehamn, Ombergsheden, Oskarkstad, Philipstad.
Storra-Kopparberg....	Dalarne......	Fahlun, Hedemora, Avesta, Mora, Husby.
Gefleborg....	Gestrikland and Helsingland...	Gefle, Soderhamn, Jarfso, Huddikswall.
GOTHALAND.		
Linkoping...	Oestergothland.......	Linkoping, Norrkoping, Wadstena, Soderkoping, Medevi, Ikeninge, Motala.
Calmar..........	Smaland.....	Calmar, Westerwik, Borgholm.
Jonkoping......	...	Jonkoping, Ædelfors, Ekesjo.
Kronoberg......	...	Wexio.
Blekinge.........	Blekinge.....	Carslcrona, Ronneby, Carlshamn.
Skaraborg...	Westergothland.......	Mariestad, Lidkoping, Skara, Vanas.
Elfsborg.....	Dasland and Westergothland..	Wenersborg, Boras, Trollhattan, Amal.
Gottenburg and Bohus	...	Gottenburg, Marstrand, Ny-Elfsborg, Uddevalla, Stromstad.
Halmstad.......	Halland........	Halmstad, Warberg, Laholm.
Christianstad........	Skania or Schonen...	Christianstad, Engelholm, Cimbrishamn.
Malmohus...	...	Malmo, Ystad, Lund, Landscrona, Helsingborg, Ramlosa.
Gottland....	Gottland Island.....	Wisby.
NORRLAND.		
Norrbotten, Westerbotten.....	Westerbotten and Lapmark..	Pitea, Lulea, Arjeplog, Gellivara, Jukkasjarvi, Umea, Asele, Sorsell.
Wester-Norland........	Medelpad and Angermanland...	Hernosand, Sundsvall.
Jamtland....	Jamtland and Herjeadalen...	Oestersund, Hede, Ijusnedal.

SWEDENBORG, Emanuel, was born at Stockholm, in Sweden, in January 1689. His father was bishop of Skara in West Gothland; member of a society for the propagation of the gospel, formed on the plan of that of England; and president of the Swedish church in Pennsylvania and London. To this last office he was appointed by Charles XII. who seems to have had a great regard for the bishop, and to have continued that regard to his son.

Of the course of young Swedenborg's education we have procured no account; but from the character of the father, it may be supposed to have been pious; and by his appearing with reputation as an author when but twenty years of age, it is proved to have been successful. His first work was published in 1709; and the year following he sent into the world a collection of pieces on different subjects, in Latin verse, under the title of "Ludus Heliconius, sive Carmina Miscellanea quæ variis in locis cecinit." The same year he began his travels, first into England, afterwards into Holland, France, and Germany; and returning to Stockholm in 1714, he was two years afterwards appointed to the office of assessor in the Metallic College by Charles XII. who honoured him with frequent conversations, and bestowed upon him a large share of his favour. At this period of his life, Swedenborg devoted his attention principally to physic and mathematical studies; and in 1718 he accompanied the king to the siege of Fredrickshall, where he gave an eminent proof that he had not studied in vain. Charles could not send his heavy artillery to Fredrickshall, from the badness of the roads, which were then rendered much worse than usual by being deeply covered with snow. In this extremity Swedenborg brought the sciences to the aid of valour. By the help of proper instruments he cut through the mountains and raised the valleys which separated Sweden from Norway, and then sent to his master two galleys, five large boats, and a sloop, loaded with battering pieces, to be employed in the siege. The length of this canal was about two miles and a half. The execution of this great work, however, did not occupy all his time. In 1716 he had begun to publish essays and observations on the mathematical and physical sciences, under the title of "Dædalus Hyperboreus;" and he found leisure during the siege to complete his intended collection, and also in the same year to publish an introduction to algebra, under the whimsical title of the Art of the Rules.

At the siege of Fredrickshall he lost his royal patron; but he found another in Ulrica Eleonora, the sister and successor of that hero, by whom in 1719 he was created a baron. His promotion did not lessen his ardour for the sciences; for he published in the same year "A Method to fix the Value of Money, and to determine the Swedish Measures in such a way as to suppress all the Fractions and facilitate the Calculations." About the same time he gave the public a treatise on "the Position and Course of the Planets;" with another on "the Height of the Tides, and Fux and Reflux of the Sea;" which, from information gathered in different parts of Sweden, appeared to have been greater formerly than when he wrote.

As Swedenborg continued, under the new sovereign, to hold the office of assessor to the Metallic College, he thought it necessary, for the discharge of his duty, to make a second journey into foreign countries, that he might himself examine their mines, particularly those of Saxony and Harts. During these travels, which were undertaken for the improvement of the manufactures of his native country, he printed at Amsterdam, 1. Prodromus Principiorum Naturalium, sive novorum Tentaminum Chemiam et Physicam experimentalem geometrice explicandi; 2. Nova Observata et Inventa circa Ferrum et Ignem, præcipue Naturam

Ignis elementarem, una cum nova Camini Inventione; 3. Methodus nova inveniendi Longitudines Locorum terra marique ope Lunæ; 4. Modus construendi Receptacula Navalia, vulgo en Dockybynadder; 5. Nova Constructio Aggeris Aquatici; 6. Modus explorandi Virtutes Navigiorum; and at Leipzig and Hamburg, 7. Miscellanea Observata circa Res Naturales, præsertim Mineralia, Ignem, et Montium Strata.

This journey was made, and these tracts published, in the compass of a year and a half; and perhaps there has not been another man, Linnæus excepted, who has done so much in so short a time. After his return in 1722, Swedenborg divided his time so equally between the duties of his office and his private studies, that in 1733 he finished his grand work, entitled "Opera Philosophica et Mineralia," and had it printed under his own direction in 1734, partly at Dresden, and partly at Leipzig. During the same year he also went to inspect the mines of Austria and Hungary. This work is divided into three volumes folio. The title of the first is "Principia Rerum Naturalium, sive novorum Tentaminum Phænomena Mundi elementaris philosophice explicandi;" of the second, "Regnum Subterraneum, sive Minerale de Ferro;" and the third, "Regnum Subterraneum, sive Minerale de Cupro, et Orichalco." The whole is written with great strength of judgment; and the work is ornamented with plates to facilitate the comprehension of the text.

In the year 1729 he was enrolled among the members of the Society of Sciences at Upsala, and was, probably about the same time, made a fellow of the Royal Academy of Sciences at Stockholm; nor were strangers less willing than his own countrymen to acknowledge the greatness of his merit. Wolfius, with many other learned foreigners, was eager to court his correspondence. The Academy of St Petersburg sent him, on the 17th of December 1734, a diploma of association as a correspondent member; and soon afterwards the editors of the *Acta Eruditorum*, published at Leipzig, recognised in his works some acceptable contributions to useful knowledge.

By many persons the approbation of learned academies would have been highly valued, but by Baron Swedenborg it was considered as of very little importance. "Whatever of worldly honour and advantage may appear to be in the things before mentioned, I hold them," says he, "but as matters of low estimation, when compared to the honour of that holy office to which the Lord himself hath called me, who was graciously pleased to manifest himself to me, his unworthy servant, in a personal appearance, in the year 1743, to open in me a sight of the spiritual world, and to enable me to converse with spirits and angels; and this privilege has continued with me to this day. From that time I began to print and publish various unknown *Arcana*, which have been either seen by me or revealed to me, concerning heaven and hell, the state of men after death, the true worship of God, the spiritual sense of the Scriptures, and many other important truths tending to salvation and true wisdom."[1]

We shall not affront the understandings of our readers by making, upon this account of the baron's *call*, such reflections as every person of a sound mind will make for himself; but it is rather remarkable, that a man who had devoted the better part of his life to the study of such sciences as generally fortify the mind against the delusions of fanaticism, and who had even excelled in those sciences, should have fallen into such a reverie as this. After this extraordinary call, Swedenborg dedicated himself wholly to the great work which, he supposed, was assigned him, studying diligently the word of God, and from time to time publishing to his fellow-creatures such important information as was made known to him concerning another world. Among his various discoveries concerning the spiritual world, one is, that it exists not in space. "Of this," says he, "I was convinced, because I could there see Africans and Indians very near me, although they are so many miles distant here on earth; nay, that I could be made present with the inhabitants of other planets in our system, and also with the inhabitants of planets that are in other worlds, and revolve about other suns. By virtue of such presence, (*i. e.* without real space), not of place, I have conversed with apostles, departed popes, emperors, and kings; with the late reformers of the church, Luther, Calvin, and Melanchthon, and with others from distant countries."[2] Notwithstanding the want of space in the spiritual world, he tells us, "that after death a man is so little changed that he even does not know but he is living in the present world; that he eats and drinks, and even enjoys conjugal delight, as in this world; that the resemblance between the two worlds is so great, that in the spiritual world there are cities, with palaces and houses, and also writings and books, employments and merchandises; that there are gold, silver, and precious stones there." In a word," he says, "there is in the spiritual world all and every thing that there is in the natural world, but that in heaven such things are in an infinitely more perfect state."

Such was his zeal in the propagation of these whimsical and sometimes sensual doctrines, that he frequently left his native country to visit distant cities, particularly London and Amsterdam, where all his theological works were printed at great expense, and with little prospect or probability of a reimbursement. "Wherever he resided when on his travels, he was," says one of his admirers, "a mere solitary, and almost inaccessible, though in his own country of a free and open behaviour. He affected no honour, but declined it; pursued no worldly interest, but spent his time in travelling and printing, in order to communicate instruction and benefit to mankind. He had nothing of the precise in his manner, nothing of melancholy in his temper, and nothing in the least bordering on enthusiasm in his conversation or writings." This is too much. We believe he was an inoffensive visionary; of his conversation we cannot judge; but the specimens that we have given of his writings are frantic enthusiasm. He died at London, March 29th, in the year 1772; and after lying in state, his remains were deposited in a vault at the Swedish church, near Radcliff-Highway.

The theological works of Baron Swedenborg are numerous, and all or most of them have been translated from Latin into English. A society has been formed in London for the express purpose of printing and circulating them. Though his followers do not appear to have been numerous during his life, they increased since his death; and a small sect still subsists in England, which derives its origin from him, and is called *the New Jerusalem Church.* The discriminating tenets of this sect seem to be the following: "Holding the doctrine of one God, they maintain that this one God is no other than Jesus Christ, and that he always existed in a human form; that for the sake of redeeming the world, he took upon himself a proper human or material body, but not a human soul; that this redemption consists in bringing the hells or evil spirits into subjection, and the heavens into order and regulation, and thereby preparing the way for a new spiritual church; that without such redemption no man could be saved, nor could the angels retain their state of integrity; that their redemption was effected by means of trials, temptations, or conflicts with evils spirits; and that the last of them, by which Christ glorified his humanity, perfecting the union of his divine with his human nature, was the passion of the cross. Though they maintain that there is but one God and one divine person, they hold that in this person there is a real Trinity; consisting of the divinity, the humanity, and the operation of them both in the Lord Jesus; a Trinity which did not exist from all eternity, but commenced at the incarnation. They believe that the Scriptures are to be interpreted, not only in a literal, but in a spiritual sense, not known to the world till it was revealed to Swedenborg; and that this spiritual sense extends to every part of Scripture, except the Acts of the Apostles. They believe that there are angels attending upon men, residing, as Swedenborg says, in their affections; that temptation consists in a struggle between good and bad angels within men; and that by this means God assists men in these temptations, since of themselves they could do nothing. Indeed Swedenborg maintains, that there is an universal influx from God into the souls of men, inspiring them especially with the belief of the divine unity. This efflux of divine light on the spiritual world he compares to the efflux of the light from the sun in the natural world. There are, says Swedenborg, two worlds, the natural and the spiritual, entirely distinct, though perfectly corresponding to each other; and at death a man enters into the spiritual world, when his soul is clothed with a body, which he terms *substantial*, in opposition to the present *material* body, which, he says, is never to rise out of the grave."

---

[1] Short Account of the Honourable E. Swedenborg.

[2] Swedenborg's Universal Theology, vol. i. p. 87.

SWEEP, in the sea-language, is that part of the mould of a ship where she begins to compass in the rung-heads.

SWIFT, JONATHAN, one of the wittiest writers of his own, and surpassed by few of any other age, was the son of an attorney, who held the office of steward to the society of King's Inns, Dublin. When the father died, it was found that he had not left behind him effects sufficient to pay his funeral expenses. At that period, his family consisted of a wife, then in a state of pregnancy, and an infant daughter. Soon after his death, his widow was delivered of a son, and the child thus ushered into a scene of indigence and grief, afterwards became the renowned dean of St Patrick's. He was born at Dublin on the 30th of November 1667. By the bounty of two brothers-in-law, neither of them in affluent circumstances, Swift's mother was maintained in some degree of comfort. The nurse to whose care her son had been confided was summoned to her native town, Whitehaven, by a dying relative, in whose will she hoped she had been remembered. The desire of gain, however, was not stronger than the love for her charge; and she finally reconciled her interest and her affection by absconding with the child. Having carried him to this town, she was authorized by his mother, whose anger was disarmed by this strange proof of her fondness, to keep him there until the recovery of his health, which she feared was too precarious to render his crossing the channel at that time a safe experiment. During their stay at Whitehaven, which lasted for three years, the nurse did not neglect little Jonathan's education; for on his return to Dublin, his mother found that he had attained to considerable proficiency in spelling, and at the age of five years he was able to read any passage in scripture.

It is not probable that any combination of circumstances could have rendered Swift a pattern of meekness and humility. Early prosperity, however, might have softened if not subdued those irascible passions which, fostered by youthful mortifications, and matured by the disappointments of after life, finally gratified those who had writhed under his merciless castigation, by converting him into "a driveller and a show." His paternal uncle, Godwin Swift, doled out the allowance for his maintenance with a very niggardly hand. This parsimony was warranted by his pecuniary circumstances, which were supposed to be in a more flourishing condition than they actually were; but Swift never reflected without bitterness on the despicable figure which the scanty liberality of his relation enabled him to make. To curse the hand that gives all that it has to bestow, appears to be both foolish and ungrateful. Perhaps, however, Swift's uncle acted the part of a vulgar patron, whose ostentatious benevolence never fails to blunt the edge of gratitude. By the bounty of this relation, limited as it was, he was, in the sixth year of his age, sent to school at Kilkenny, from which in 1682 he was removed in his fourteenth year to Trinity College, Dublin. His academical career gave no promise of future eminence. Being persuaded that the syllogistic subtleties which were regarded by the Dublin tutors as the perfection of knowledge, instead of teaching the art of reasoning, only taught the art of wrangling, Swift turned with disgust from such scholastic exercises. The consequence was, that when he applied for the degree of A. B. he had not even acquired the jargon of the schools; and the degree was only conferred upon him *speciali gratia*, or, in other words, he owed to favour what he could not claim by merit.

At this period died his uncle Godwin, leaving his affairs in great disorder. His studies were now in some danger of being abruptly terminated; but another uncle, Dryden William Swift, befriended him in the hour of need, and seems to have drawn his purse with a better grace than his brother, for Swift speaks of him as "the best of his relations." The consciousness of poverty and dependence, and of the mortifying circumstances under which he obtained his degree, he endeavoured to dissipate in a variety of those frolics by which a careless genius now and then, but more frequently an indolent blockhead, endeavours to get rid of a painful sense of insignificance, and to acquire, at an easy rate, the character of a youth of spirit. He neglected attending lectures and divine service, frequented taverns, absented himself from college at unseasonable hours, and was finally convicted of contemptuous insolence to Owen Lloyd, the junior dean. Of that functionary, who afterwards obtained a comfortable provision in the church by marrying a cast-off mistress of the duke of Wharton, he was obliged to beg pardon on his bended knees.[1] The atrocious sentiments that must have fermented in a mind like Swift's, when compelled to submit to such a degradation as this, may be imagined from his conduct to others who provoked his wrath when he was in a better condition to make it felt. Such a mode of punishment reflects more infamy upon those who inflicted, than upon him who endured it; but no spectacle can be more useful to those that think superior endowments can rescue them from the mortifying consequences of indiscretion, than Jonathan Swift grovelling at the feet of one of the most despicable of mankind.

In 1688, when he was in the twenty-first year of his age, Swift quitted Ireland, a country which, although it was the land of his birth, he always regarded as a place of exile. Having repaired on foot, as it is said, to his mother's residence in Leicestershire, he consulted with her about his future prospects, which looked sufficiently gloomy. She advised him to pay his court to Sir William Temple, who was connected with her family by marriage. To Temple he accordingly presented himself; and his forlorn plight procured him what he was in some danger of forfeiting by his sullenness and oddity of manners, a home under the roof of the veteran statesman. But Swift applied himself with intense assiduity to his studies, and thus became qualified to amuse the learned leisure of his patron. In Sir William's house, where he remained two years, he formed an acquaintance with no less a personage than King William the Third, who offered to make him a captain of horse. The only favour however which he ever received at the royal hands, was a lesson that his majesty gave him one day in the garden, on the Dutch mode of cutting asparagus. Swift was now in such high trust with Sir William, that he was employed by him to lay before the king some arguments in favour of triennial parliaments. This negociation was fruitless; for all the reasoning of Temple, reinforced by the eloquence of Swift, could not persuade King William that the proposed measure threatened no danger to the royal prerogative. Swift returned to Moorpark not a little crest-fallen, and often spoke of this lame conclusion of his dignified commission as a cure for vanity, less palatable than efficacious. He was now afflicted with a disorder which he had contracted in his youth by a surfeit of fruit. Giddiness and deafness were the symptoms of his malady, which visited him, after a longer or shorter respite, until the close of his life. Being advised to go to Ireland, he proceeded to that kingdom; but finding no benefit from his native air, he returned to Sir William Temple's, where he resumed his studies. He had a notion that violent exercise was of advantage to his complaints, and used to leave his books every two hours for the purpose of running up and down a hill.

---

[1] See Dr Barrett's Essay on the earlier Part of the Life of Swift, p. 15. Lond. 1808, 8vo. The chief aim of that production seems to be to fasten upon Swift the paternity of a certain Tripos, a satirical effusion, without sense or humour. It has been frequently asserted that Swift's faculties came very slowly to maturity; but it would be more just to say that it was late before he had an opportunity of displaying them. While a student at Dublin, he had sketched his Tale of a Tub, the knowledge of which fact is alone sufficient to rescue him from the charge of having written, or assisted in writing, such a contemptible rhapsody as the Tripos.

In 1692 he visited Oxford, and took the degree of A. M., which was conferred upon him with marks of distinction that fully consoled him for the contemptuous testimonial which he had received from his own university. About this period he occupied a portion of his time in the composition of verses. Besides some less ambitious attempts, he was persuaded by Sir William and Lady Temple to write Pindaric odes in the metaphysical manner of Cowley. These insipid dithyrambics, for such they are, he is said to have submitted to the inspection of Dryden, who observed with more candour than politeness, "Cousin Swift, you will never be a poet." This prediction filled the versifier with a degree of hatred which the death of the prophet did not abate.

Every rich man can have an obsequious fool to commend his sagacity, and the loss of a stupid parasite is easily supplied; but it is not always that the society of wit and learning is be obtained in exchange for the necessaries of life. Of this truth Temple was fully aware, and was in no haste to relieve Swift from the burden of dependence. Instructive as Sir William's conversation is said to have been, Swift would gladly have obtained some suitable employment, at the expense of a final separation from his accomplished patron. When Temple learned which way his wishes pointed, he offered to make him deputy-master of the rolls in Ireland, the duties of which office he knew Swift had neither inclination nor ability to discharge. After some angry discussion, he left Temple's house and went to Dublin. There he proposed to enter into holy orders, but was overwhelmed with chagrin when he learned that the bishops required a certificate of his character from the very man whom he had hoped to mortify, by evincing that he stood no longer in need of his assistance. Before he could bring his mind to solicit this attestation of his conduct, Swift deliberated nearly five months. The letter which he at last addressed to Temple has been preserved, and it appears to be the composition of a man perfectly stupified by the humiliating task that was imposed upon him. Although he acted the petitioner's part with the worst grace in the world, Temple did what was required, and Swift was admitted to orders; soon after which he obtained from Lord Capell the prebend of Kilroot, which was worth about one hundred pounds a year. The life of a country parson was not at all adapted to the taste of Swift; and Temple soon discovered that, in the loss of his conversation, he had been deprived of the chief comfort of his declining years. Temple had neither time nor inclination to search for new companions, and Swift was recalled, with a request that he would resign his Irish prebend, and a promise that an English one would be procured for him in its stead. With this summons the insipidity of the life which he led at Kilroot, or perhaps better motives, induced him to comply. To Moorpark he accordingly returned in 1695, and lived there until Sir William's death, which happened in 1699. Temple left him a legacy of a hundred pounds, and made him his literary executor. The king had promised Sir William to bestow upon Swift the first vacant prebend of Westminster or Canterbury. By way of refreshing his majesty's memory, Swift dedicated to him Temple's posthumous works, but without success. He attended for some time at court, but with no better result; and the name of this prince appears in the long list of those whom Swift detested with a cordiality that could admit of no increase. He gladly abandoned his fruitless solicitation, and accompanied the earl of Berkeley to Ireland, as his chaplain and private secretary. But a person called Bushe found means to persuade his lordship that a clergyman was not a proper secretary for a viceroy. He then offered his own services, and they were accepted. Swift was not a man to be trifled with, and his lordship was fain to pacify him by a promise of the first good living in his gift. The deanery of Derry soon afterwards became vacant, and when Swift felicitated himself in the anticipation of immediate preferment, he was waited upon by Bushe, who gave him to understand that he might have the living for a thousand pounds. "God confound you both for a couple of scoundrels!" Swift furiously exclaimed, and rushed out of the castle. But Berkeley had seen some specimens of his chaplain's talents in the way of pasquinade, and thought it best to arrest his hand by presenting him with the rectory of Agher, and the vicarages of Laracor and Rathbeggan. To these the prebend of Dunlavin was added in the year 1700; but the income arising from all his preferments amounted to a sum very inferior to the emoluments of the deanery, which probably fell to the share of some ecclesiastic, who, in addition to his piety and learning, was possessed of a little ready money.

Swift is now to be viewed in the character of a lover, which he sustained with his usual eccentricity. He had an unhappy propensity to cultivate intimacies with women, whose partiality gratified his vanity, while his constitution protected him against the assaults of beauty. This unwarrantable pastime, in which he probably indulged without reflection, caused him incredible misery when living, and has left a deep stain upon his memory. When a mere lad, he appears to have trifled with the affections of a country girl, who was his mother's neighbour in Leicestershire. He next wrote a love-letter to a Miss Waryng. This composition is so stupid and extravagant, that it is difficult to conceive it to have been traced by the pen of Swift. The most bungling courtship, however, is often successful with ladies who have no rooted aversion to matrimony; and Swift's love affairs thrived so much better than he wished, that he was compelled to write a second letter in a style of the most cutting indifference, in order to counteract the effect of the first, which was couched in heroic terms. This epistle produced the desired effect, and Swift was freed from the importunities of Miss Waryng. The warning which he had thus received was insufficient to deter him from committing similar follies. No sooner was he settled at Laracor, than he decoyed from England the daughter of Sir William Temple's steward. This lady, whose name was Johnson, and upon whom Swift bestowed the fanciful appellation of Stella, had been left by Sir William a legacy of a thousand pounds; and the higher rate of interest given in Ireland was the ostensible reason for her taking up her residence in that kingdom. She was accompanied by Mrs Dingley, a person in humble circumstances, and of feeble capacity, whose presence was designed to obviate calumny. Swift and Stella never met but in the presence of this or of some other third party: when he was absent, she and her friend lived in his parsonage, and shifted their quarters on his return. A rival in the affections of Stella appeared in Dr William Tisdale, a clergyman, whose notions on the subject of love resembled those of ordinary mortals. But Swift could not endure to see in the arms of another, a woman who would gladly have thrown herself into his own; and by his machinations this vulgar suitor was rejected. These tortuous ways, however, never conducted him to happiness; and with all his caution, Swift was only laying up for himself a fund of obloquy.

Excepting a few poetical essays, which cannot be called the foundation of his literary fame, Swift had hitherto published nothing. In 1701, when he was in his thirty-fourth year, appeared the "Dissensions in Athens and Rome." This work, which excited much attention, was attributed to Burnet. Some critics, still more undiscerning, afterwards fathered upon Swift the Characteristics of Shaftesbury, whose general manner of writing is as verbose, ambitious, and declamatory, as that of Swift is concise, simple, and didactic; whose pleasantry is languid and insipid, while the sarcasm of Swift is withering, and his irony irresistible.

In 1704 was published "A Tale of a Tub." There cannot be a doubt that Swift thought this performance calculated to serve the Church of England; but he executed his task in a manner so likely to produce ludicrous impressions of religion in general, that Voltaire immediately extended to him the right hand of fellowship, and hailed him as "le Rabelais d'Angleterre." And the weapons with which he assails the Catholics and Presbyterians are not much more dignified than the flail and urinal with which he has equipped Bentley in the Battle of the Books. But whether this production is fitted to promote the interests of piety or retard them, it is scarcely hyperbolical to say, that to produce the same quantity of wit and humour in the same space, the exchequer of human knowledge would be ransacked in vain. His literary offspring, however, being more beautiful than exemplary, Swift had no wish to own it; but a clerical namesake and relation of his, who was willing to acquire the reputation of a wit, at the expense of being considered a little profane, confessed that he had some share in the composition of the Tale of a Tub. But those who were willing to take his own word for his impiety, had strong doubts of his wit; and his self-accusation may now be treated as modern judges treat the confessions of old women who acknowledge having dealings with the evil one.

The hint of the Battle of the Books was said to have been taken from Coutray's "Histoire Poétique de la Guerre nouvellement déclarée entre les Anciens et les Modernes." Johnson has given ear to this assertion; but the works of Coutray and Swift are more dissimilar from each other than Rasselas and Candide. The "Dissertation on the Mechanical Operation of the Spirit," is written in Swift's happiest vein, and his blows are aimed with good will.

In 1708 appeared "The Sentiments of a Church of England Man;" that inimitable ridicule of astrology in general, and of one impostor, Partridge, in particular, "Predictions for the year 1708, by Isaac Bickerstaff, Esq.," a name afterwards adopted by Steele in the Tatler; "An Argument against abolishing Christianity," one of his happiest efforts in the ironical style; and the "Letter on the Sacramental Test." The publication of the last-mentioned tract was regarded as a signal of retreat from the standard of the Whigs; and, with the exception of the dispassionate Addison, all his friends of that party became cold and estranged. Nor were their suspicions unfounded. During this year Swift was employed by Archbishop King and the Irish prelacy, to solicit the remission of the first fruits and twentieth parts, in order to augment the incomes of the poorer clergy. But the experiment had been tried in England without converting the ecclesiastics from Toryism; and Godolphin declined conferring a like expensive favour on the Irish divines, many of whom he suspected to be disaffected to the government as well as the ministry. Finding that this negociation in behalf of his brethren was a hopeless undertaking, Swift endeavoured to promote his own interest in the best way he could. He had some prospect of being appointed secretary of an embassy to Vienna; but Lord Berkeley, whom he was to accompany, was detained in England by the infirmities of age. Interest was next exerted to procure his nomination as bishop of Virginia; but that scheme also proved abortive. He was now convinced that the Whigs would do nothing for him. Disgusted with compliments that could not long cajole a man of his penetration and knowledge of the world, and tired of waiting for the fulfilment of promises made with all the alacrity, and performed with the usual punctuality of a court, Swift returned, in no enviable frame of mind, to his Irish parsonage. During his stay in London, however, he had written his "Project for the Advancement of Religion;" which in some parts is more Utopian than might have been expected from his pen.

Swift was not long buried in the solitude of Laracor; for in 1710 he returned to England, being associated in the commission with the bishops of Ossory and Killaloe, who, in the impending change of ministry, were sent to renew the suit which he had formerly preferred without success. It was arranged that if the two bishops should leave London without bringing the matter to a satisfactory issue, Swift should remain to negociate with government to the best of his ability.

On the 1st of September 1710, he left Ireland, and on the 9th of that month reached London, where he was speedily plunged in business. His Journal to Stella, one of the most singular records that have been submitted to public inspection, gives a minute account of this stirring period of his history. With the exception of Godolphin, whose calm indifference had probably accelerated his political apostasy, the Whigs treated him with marked respect. But the politeness of those who seemed resolved to starve him into hostility when they were in a condition to be of service to him, he estimated at its real value. Somers stooped to make explanations which Swift did not think satisfactory; and Godolphin's disdain he endeavoured to humble by means of a lampoon. He was soon afterwards introduced to Harley, refusing on the same day an invitation from Lord Halifax. Harley made him acquainted with St John, and both evinced the utmost eagerness to bind him to their interests. Swift asserted with great composure, that although a Whig in politics, he had always been a Tory in church affairs. A man that goes over to a victorious enemy, must say something to his new comrades, who, if his services are of any value, will readily admit his apologies: on his former associates his eloquence will in all likelihood be thrown away. From his Journal to Stella, it is manifest that Swift's standard of political consistency was extremely low, and that he was ready to grasp the hand, whatever cause it maintained, that had any thing to give, or that could apply a balsam to the wounds of pride.

To prop the interest of the new rulers, Swift was required to conduct the Examiner, which was the organ of the ministerial party. Addison for some time opposed that publication in a paper called the Whig Examiner, but withdrew from the contest when he heard that Swift was about to take the field, probably because his gentle spirit detested the thoughts of entering the lists with a friend. Swift conducted the Examiner from the 10th of November 1710, to the 14th of June 1711. During that period he attacked his opponents with the utmost fury, using against them all the arms of wit, sharpened by the first fervours of new-born zeal.

Immersed as he was in general politics, Swift did not neglect the object of his mission; and his interest with the ministry speedily obtained the boon that had so long been desired. But when he expected to be overwhelmed with the grateful acknowledgments of his brethren in Ireland, he received the astounding intelligence that the bishops had resolved to dispense with his services, and to put their trust in the duke of Ormond. The motive for recalling a commission, the object of which they were not aware had been already obtained, was an apprehension that Swift had formerly been too much caressed by the Whigs to have any influence with the party in power. When apprized of his triumph, Archbishop King apologized to the exasperated nuncio in a clumsy manner. In 1712 Swift published "The Conduct of the Allies," and no political pamphlet ever produced more powerful effects. He proved that a prodigal expenditure of blood and treasure had secured to the English nation nothing but a few sprigs of laurel to decorate the empty heads of those chivalrous simpletons who fought the battles of ungrateful knaves, without any prospect of benefit to themselves. To state facts so strong as these requires little force of eloquence; nor does Swift's pamphlet strike the reader of the present day as a very masterly specimen of writing. But when the blow is aimed at a vital part, it is unnecessary that the assailant should put forth all his strength. In the space of one week four editions were sold; the ministerial members quoted it in the House of Commons, and the other party talked of bringing the author to the bar of the House of Lords. The same year produced "A Proposal for correcting, improving, and ascertaining the English Tongue," a publication which added nothing to his reputation; and "Reflections on the Barrier Treaty," which are a sequel to the Conduct of the Allies.

In the character of a patron, Swift appears to great advantage. If he sometimes neglected the forms of politeness, he was never slow in conferring substantial benefits on meritorious persons. He was never more in his element than when he was distributing preferment, and few have made a more commendable use of their power. Lord Bacon has said that "prosperity doth best discover vice, but adversity doth best discover virtue." In order to apply to Swift, this apophthegm must be reversed. In his prosperous days, he exerted his influence to retain the most deserving of his political opponents in their places, and performed many other generous actions; but when he awoke from the flattering dream of ambition, his heart, thus ennobled by good fortune, became the chosen residence of some of the worst passions of our nature.

Although his recommendation in favour of others was seldom neglected by his great friends, they seemed in no haste to provide for Swift himself. This, however, was no fault of theirs, but of the duchess of Somerset, whom he had lampooned. He held her up to public detestation, as being accessary to the murder of her husband, a calumny which she might have forgiven; but he also laughed at her red hair, and she vowed revenge. An opportunity soon afterwards occurred of presenting Swift to the see of Hereford; but the freckled favourite threw herself at the feet of her royal mistress, and with streaming eyes begged that her inhuman satirist should be refused the vacant mitre. The entreaties of the ministers were drowned in her clamours for revenge; and Swift, instead of obtaining an English bishopric, was rewarded for his services by an Irish deanery. This was the effect produced by the Windsor Prophecy; and the tears of one favourite marred the fortunes of Swift, the pertinacity of another, Mrs Masham, having, not long before, deprived Marlborough of all his employments, and occasioned the downfall of the Whig ministry. From such despicable sources do important events sometimes take their rise.

Soon after Swift went to take possession of his deanery of St Patrick's, Dublin, he was summoned to reconcile Oxford and Bolingbroke, whose increasing animosity to each other threatened destruction to the Tory interest. Swift hastened to England, but his journey was fruitless; for he found that it was no temporary misunderstanding, from which they might be extricated by his wit and pleasantries, but that a rooted hatred had sprung up between them, which defied the most dexterous mediation.

"The Public Spirit of the Whigs" appeared in 1714. It is a virulent reply to Sir Richard Steele's Crisis, the pamphlet that procured his expulsion from the House of Commons. At the intercession of Swift, Steele had been permitted to retain his post of commissioner of stamp-duties; but, blinded by ignorance or the rage of party, he denied the obligation and reviled his benefactor. It is intolerable to be upbraided with favours which one is not conscious of having received, and the careless Steele perhaps took little trouble to inquire who had been his friend; but he was not a man to be guilty of deliberate ingratitude.[1] In this pamphlet Steele was attacked without mercy; and the Scotish nation was there treated with such insolence and rancour, that the duke of Argyle, accompanied by other northern peers, went to court to demand the punishment of the author. A reward of three hundred pounds was offered for his discovery; and Morphew the bookseller, and Barber the printer of the obnoxious pamphlet, were ordered into the custody of the black rod; but the ministers, by directing a prosecution against these men, for the expenses of which they were privately idemnified by a sum given to Swift for that purpose, disappointed the vengeance of the Scotish nobles. Nor is this much to be regretted; for he must be a very facetious person whose gibes can obscure the lustre of national renown; and to give importance to a libel by persecuting the author, is more patriotic than dignified.

Dr Swift's political importance was now drawing near its close. In June 1714 he retired to a friend's house in Berkshire, where he wrote "Free Thoughts on the present State of Public Affairs;" a tract which was then suppressed. At this period occurred the death of the queen, which restored his enemies to power, and drove him into Ireland to avoid the spectacle of their triumph. This event also deprived him of a thousand pounds, for which he had an order upon the exchequer.

During his residence in England, Swift formed another anomalous and tender connexion, which was followed by very tragical consequences. Miss Esther Vanhomrigh was the daughter of a widow lady of considerable fortune. At the house of Mrs Vanhomrigh he was a frequent visitor; and being struck with the contempt which the young lady displayed for the fopperies of the age, he took upon himself the dangerous task of directing her studies. The result was, that she conceived a passion for her instructor as impetuous as that which swelled the breast of Eloisa. Throwing aside maidenly reserve, she confessed her flame; and Swift had not sufficient fortitude to deprive himself of her society by owning his engagement with Stella. He offered her his friendship, which she rejected with disdain, and persisted until the end of her life in endeavouring to extort a more lively return of her passion. Had Swift been as other men, such sighs as hers could scarcely have been breathed in vain. The irascible passions he indulged without either compunction or remorse; his appeared to be the Indian's creed, that revenge is virtue; and there is no glaring uncharitableness in supposing, that with the same temptation, and the same means of gratification, he would have yielded to the passion of love. There is, however, strong reason to suppose that he laboured under a physical incapacity. When Swift returned to Ireland, he was followed by Miss Vanhomrigh, who renewed her efforts to awake his tenderness. To render his perplexity insupportable, Stella began to droop, and it was in vain for him to affect ignorance of the cause. To save a life which was gradually wasting away under the agony of "hope deferred," he consented that the nuptial blessing should be pronounced over Stella and himself, upon condition that they should continue in all respects to live as before. Stella was thus silenced, if not content; but Miss Vanhomrigh petitioned with frantic eagerness for that requital of her passion which neither the guilt nor innocence of her lover could bestow. At length her impatience became incapable of control, and she addressed a letter to Stella, desiring to know the nature of her connexion with the dean. Stella replied that they were married; and having sent Miss Vanhomrigh's letter to Swift, she retired, full of just indignation, to the house of a friend at some distance from Dublin. In a paroxysm of rage, he rode to Marley Abbey, the residence of Stella's miserable rival. With terror in her looks she begged in a trembling voice that her infuriated visitor would be seated. He answered by tossing her own letter to Stella on the table, and remounting his horse, rode back to town without having opened his lips. Miss Vanhomrigh only survived this interview a few weeks. The celebrated poem of Cadenus and Vanessa, the name which Swift had bestowed upon her, was given to the world soon after her death. That melancholy event appeased the anger of Stella.

---

[1] In a petulant letter to Swift relative to this affair, Steele says, "They laugh at you, if they make you believe your interposition has kept me thus long in my office." To which Swift replies with unanswerable force of reason, "Suppose they did laugh at me, I ask whether my inclinations to serve you merit to be rewarded by the vilest treatment, whether they succeeded or not? If your interpretation were true, I was laughed at only for your sake; which, I think, is going pretty far to serve a friend."

In 1724, the far-famed Drapier's Letters disappointed the rapacity of Wood, who had obtained by patent the right of circulating halfpence and farthings to supply the deficiency of copper coinage in Ireland. These letters raised Swift to an unexampled height of popularity, although it would not be easy to prove that they had any better effect than that of intercepting the royal bounty. In 1727, Swift went to England, and, in conjunction with Pope, collected three volumes of Miscellanies. The same year produced Gulliver's Travels. In comparing that singular production with Lucian's True History, the work of the pupil must, in common candour, be preferred to that of the master. If Lucian has any covert meaning at all, it must be a design to ridicule credulous and lying travellers and historians. The introductory part of his narrative contains a promise, which he punctually fulfills, of relating a series of incredible wonders; and these have too much the aspect of a feverish dream to be a direct satire upon any modification of human absurdity. Swift, on the other hand, speaks in parables, it is true; but they are so plain, that he who runs may read. Those who think favourably of the sense and virtue of mankind, may detest the writer whose chief solicitude is to wound the vanity of his readers; but he can be at no loss to perceive that the ferocious scoffer laughs at all human dealings. Indeed there is little hazard in asserting, that the satire which is not obvious is good for nothing; and that lucubrations positively hazy are only for times when a man writes with a retainer of justice at his elbow.

When George I. died, Swift had probably some expectations from the new queen, who had sent him several complimentary messages, and seized upon some Irish silk which the dean had sent to Mrs Howard, her husband's mistress, with whom she lived on very amicable terms. Wearing his silk, however, was the chief favour he ever received at her hands. She even broke a promise which she had made of sending him some medals; and he always spoke of her with aversion and contempt. For the latter feeling there is some ground, if she transmitted to him her grateful acknowledgments, as he said she did, for some of the bitterest irony that he ever wrote.

Towards the end of the year 1737, he had an attack of his old complaints, giddiness and deafness. He was then living in the house of Pope, which he left in a strange abrupt manner; but a letter of apology that he afterwards addressed to the poet was sufficient to atone for a graver offence. He hastened to a cheerless home; for he found Stella on the confines of the tomb, which sorrow and disease had probably stript of half its terrors. She expired on the 28th of January 1738, aged forty-four years. Thus died this unfortunate woman, whose history is inseparably connected with that of one of the most extraordinary persons whom this country has produced.

After the death of Stella, he endeavoured to dissipate his grief by directing his attention to public affairs; with what satisfaction to himself, the following passage from one of his letters to Pope will show. "I do profess, without affectation, that your kind opinion of me as a patriot (since you call it so) is what I do not deserve; because what I do is owing to perfect rage and resentment, and the mortifying sight of slavery, and folly, and baseness, about me, among which I am forced to live."

In order to rescue Swift from the charge of fondness for low society, Dr Delany has displayed a long list of Irish worthies with whom the dean lived in habits of intimacy.[1] That he was addicted to the society of the lowest vulgar, there is no reason to believe; but that he preferred his inferiors in fortune and intellect as constant companions, he has himself acknowledged. In a letter to Pope, dated May 10, 1728, he says, "I reckon that men subject like us to bodily infirmities, should only occasionally converse with great people, notwithstanding all their good qualities, easiness, and kindnesses. There is another race which I prefer before them, as beef and mutton for constant diet before partridges; I mean a middle kind both for understanding and fortune, who are perfectly easy, never impertinent, complying in every thing, ready to do a hundred little offices that you and I may often want, who dine and sit with me five times for once that I go to them, and whom I can tell, without offence, that I am otherwise engaged at present." His exactions, which indeed no man could endure whose admiration of Swift did not outweigh respect for himself, became at last too tyrannous even for those humble friends. There can be few inducements to frequent a house where there is neither civility nor good cheer; and Swift found himself alone when age and sickness rendered solitude exceedingly dismal. Books, his usual resource against the languor of the hour, he could no longer read with the naked eye, and spectacles he had made some absurd resolution never to use. But if he could not be loved, he had not ceased to be an object of fear; for a few strokes of his envenomed quill reduced Serjeant Bettesworth, a lawyer who was in the constant habit of reviling the clergy, from affluence and professional celebrity to poverty and contempt. Nor did he desist from those acts of charity and benevolence, in which, however ungraciously performed, he had never been remiss. To indigent persons he lent out five hundred pounds, in sums of from five to ten pounds; and his memory is still revered in many families which owe their prosperity to his judicious beneficence. Johnson, who, as Parr said of him, "weighed every man in the balance of the sanctuary," but whose narrative is not a little tinged with the spleen that he condemns in the subject of it, talks of Swift employing "the catch-poll under the appearance of charity." That Swift would not suffer profligate paupers to cheat him with impunity, it is easy to conceive; but there are few who would relish either the trouble or the risk of affording honest industry such chances of emerging from poverty. Besides, a man who parts with what he has no desire to keep to himself, does nothing meritorious: but Swift loved money as much as he hated mankind; his alms-giving, therefore, was a signal triumph over avarice and misanthropy, and the conqueror is worthy of his garland.

---

[1] Delany's Observations upon Lord Orrery's Remarks on the Life and Writings of Dr Jonathan Swift, p. 90. Lond. 1754, 8vo.

In 1737, Swift took some steps toward publishing his History of the Peace of Utrecht, which he had written in 1714, and the title of which he altered to that of "The History of the four last years of Queen Anne." The literary modesty, or indifference to literary renown, for which he was remarkable through life, induced him to listen to the suggestions of the meanest critics, and he was persuaded to abandon the idea of publishing this work. It appeared in 1758, but the dean would have lost little credit as an author if it had been entirely suppressed; for it sinks beneath the dignity of historical narrative, and has no pretensions to the candour of political sentiment. "Polite Conversation" appeared in 1738. It is an admirable satire on the pert retailers of conventional jocularity. The "Directions for Servants" were not printed until some time after his death.

The misanthropical musings in which he was constantly absorbed, at length terminated in madness. He was visited by that dreadful affliction in 1741, when legal guardians were appointed for his custody and sustentation. From the condition of a furious maniac, he gradually sunk into that of a harmless idiot; and in this lamentable situation he lingered until the 29th of October 1745, when he resigned a state of existence that only served to illustrate the precarious tenure upon which the favourites of nature hold her gifts. He was interred in St Patrick's cathedral, where an appalling mural inscription, composed by himself, informs the reader who sleeps below. It is of the following tenor:

Hic depositum est corpus
JONATHAN SWIFT, S. T. P.
hujus Ecclesiæ Cathedralis
Decani;
ubi sæva indignatio
ulterius cor lacerare nequit.
Abi, viator,
et imitare, si poteris,
strenuum pro virili libertatis vindicem.
Obiit anno (1745)
mensis (Octobris) die (29),
Ætatis anno (78).

Swift was tall, muscular, and well formed. His complexion was swarthy, and somewhat scorbutic; his aspect was forbidding; and but for his eyes, which were blue and of uncommon brilliancy, his features would have conveyed an expression of sombre arrogance. He was never known to laugh, and there was little gaiety in his smiles. His conversation had many attractions; in jest and repartee he was unrivalled, and related anecdotes with singular felicity. In his latter days, however, he was apt to go over the same ground too often. He was irascible and vindictive; but whether he was implacable or not, it is difficult to determine; for when provoked he struck so hard as to leave no room for reconciliation. His efforts to serve his friends, however, were as energetic as his attacks upon his enemies. Nor were his attachments of the holiday kind; for his love of Bolingbroke was not diminished by exile and proscription, and he was ready to wait upon Oxford in the Tower.

Notwithstanding his hatred of sectaries, it has been doubted whether the dean was a Christian. In the Tale of a Tub, his likening the cross to an old sign-post, and other indecorous pleasantries in the same performance, give some colour to the charge of infidelity which has been brought against him. Red-hot zeal for the interests of a particular church may be connected with a total unconcern for the interests of religion. This species of zeal only embraces the emoluments, dignities, and privileges of the clergy. It must however be kept in mind, that Swift had a mode of doing every thing peculiar to himself. He complimented his friends in ironical abuse, and abused his enemies in ironical compliments; and to his eccentric fancy a facetious panegyric on the number three, might perhaps appear as proper a way of defending the doctrine of the Trinity as any other. As a son, Swift was dutiful and affectionate to a remarkable degree. His sister, who had made a mean marriage, he relieved, but never pardoned. With his servants he was peevish and exacting, but was always prepared to render them important benefits when he had it in his power. The fruits of many years economy he bequeathed to found an asylum for lunatics. Against avarice he maintained a violent and successful struggle; but pride, ambition, and revenge were always masters of the field. His minor failings were a love of flattery, and a childish and petulant mode of conducting himself towards his superiors, which he mistook for dignity.

Upon the character of Swift as an author it is unnecessary to expatiate. No one is ignorant of his merits, and his faults are equally notorious. In grave irony he is second to none, and the writings of few are more deformed by obscenity and physical indelicacy. In his serious style, although it is easy and perspicuous, he is excelled by many. In his zeal for simplicity, he often borders upon meanness, as his own Jack is represented to have disfigured his coat by rudely tearing off its superfluous decorations. Swift had great skill in versification; but most of his poems were designed only for the inspection of his private friends, and his muse is often sportive, and generally trifling. Poetry he cultivated without any view to fame or profit, but in order to solace a mind that preyed upon itself when unemployed. To his reputation as a writer of prose he was equally indifferent. Posterity however has willingly extended to him that renown which is often withheld from more eager claimants; and it would be vain to contest his right to be considered a British classic of the first rank.

SWIMMING, the art of floating one's self on water, and at the same time making a progressive motion through it. As swimming is not natural to man, it is evident that at some period it must have been unknown among the human race. Nevertheless there are no accounts of its origin to be found in the history of any nation; nor are there any nations so barbarous but that the art of swimming is known among them, and that in greater perfection than among civilized people. It is probable, therefore, that the art, though not absolutely natural, will always be acquired by people in a savage state, from imitating the brute animals, most of whom swim naturally. Indeed so much does this appear to be the case, that very expert swimmers have recommended it to those who wished to learn the art, to keep some frogs in a tub of water constantly beside them, and to imitate the motions by which they move through that element.

Swimming not natural to man.

Depends on a simple principle.

The theory of swimming depends upon one very simple principle; namely, that if a force be applied to any body, it will always move towards that side where there is the least resistance. Thus, if a person standing in a boat pushes with a pole against the side or any other part of the vessel in which he stands, no motion will ensue; for as much as he presses in one direction with the pole, just so much does the action of his feet, on which the pressure of the pole must ultimately rest, push the vessel the other way: but if, instead of the side of the vessel, he pushes the pole against the shore, then only one force acts upon it, namely, that of the feet; which being resisted only by the water, the boat begins to move from the shore. Now the very same thing takes place in swimming, whether the animal be man, quadruped, bird, or fish. If we consider the matter simply, we may suppose an animal in such a situation that it could not possibly swim: thus, if we cut off the fins and tail of a fish, it will indeed float in consequence of being specifically lighter than the water, but cannot make any progressive motion, or at least but very little, in consequence of wriggling its body; but if we allow it to keep any of its fins, by striking them against the water in any direction the body moves the contrary way, just as the boat moves the contrary way to that in which the oars strike the water. It is true, that as the boat is but partly immerged in the water, the resistance is comparatively less than when a frog or even any other quadruped swims; but a boat could certainly be rowed with oars though it were totally immerged in water, only with less velocity than when it is not. When a man swims, he in like manner strikes the water with his hands, arms, and feet; in consequence of which the body moves in a direction contrary to the stroke. Upon this principle, and on this only, a man may either ascend, descend, or move obliquely in any possible direction, in the water. One would think, indeed, that as the strength of a man's arms and legs is but small, he could make but very little way by any stroke he could give the water, considering the fluidity of that element. Nevertheless it is incredible what expert swimmers will perform in this way; of which Dr Forster gives a most remarkable instance in the inhabitants of Otaheite, whose agility, he tells us, was such, that when a nail was thrown overboard, they would jump after it into the sea, and never fail to catch it before it reached the bottom.

As to the practice of swimming, there are but few directions which can be given. The great obstacle is the natural dread which people have of being drowned; and this it is impossible to overcome by any thing but accustoming ourselves to go into the water. With regard to the real danger of being drowned, it is but little; and on innumerable occasions arises entirely from the terror above mentioned, as will appear from the following observations by Dr Franklin.

Observations by Dr Franklin.

"1st, That though the legs, arms, and head, of a human body, being solid parts, are specifically somewhat heavier than fresh water, yet the trunk, particularly the upper part, from its hollowness, is so much lighter than water, as that the whole of the body, taken together, is too light to sink wholly under water, but some part will remain above until the lungs become filled with water; which happens from drawing water into them instead of air, when a person in the fright attempts breathing while the mouth and nostrils are under water.

"2dly, That the legs and arms are specifically lighter than salt water, and will be supported by it; so that a human body would not sink in salt water though the lungs were filled as above, but from the greater specific gravity of the head.

"3dly, That therefore a person throwing himself on his back in salt water, and extending his arms, may easily lie so as to keep his mouth and nostrils free from breathing; and by a small motion of his hands may prevent turning, if he should perceive any tendency to it.

"4thly, That in fresh water, if a man throws himself on his back near the surface, he cannot long continue in that situation, but by a proper action of his hands on the water. If he uses no such action, the legs and lower part of the body will gradually sink till he comes into an upright position, in which he will continue suspended, the hollow of the breast keeping the head uppermost.

"5thly, But if in this erect position the head is kept upright above the shoulders, as when we stand on the ground, the immersion will, by the weight of that part of the head that is out of the water, reach above the mouth and nostrils, perhaps a little above the eyes; so that a man cannot long remain suspended in water with his head in that position.

"6thly, The body continued suspended as before, and upright, if the head be leaned quite back, so that the face looks upwards, all the back part of the head being then under water, and its weight consequently in a great measure supported by it, the face will remain above water quite free for breathing, will rise an inch higher every inspiration, and sink as much every expiration, but never so low as that the water may come over the mouth.

"7thly, If therefore a person unacquainted with swimming, and falling accidentally into the water, could have presence of mind sufficient to avoid struggling and plunging, and let the body take this natural position, he might continue long safe from drowning, till perhaps help would come; for as to the clothes, their additional weight while immersed is very inconsiderable, the water supporting it; though when he comes out of the water, he would find them very heavy indeed."

His method of learning swim,

The method of learning to swim is as follows. The person must walk into water so deep that it will reach to the breast. He is then to lie down gently on the belly, keeping the head and neck perfectly upright, the breast advancing forward, the thorax inflated, and the back bent; then withdrawing the legs from the bottom, and stretching them out, strike the arms forwards in unison with the legs. Swimming on the back is somewhat similar to that on the belly, but with this difference, that although the legs are employed to move the body forwards, the arms are generally unemployed, and the progressive motion is derived from the movement of the legs. In diving, a person must close his hands together, and, pressing his chin upon his breast, make an exertion to bend with force forwards. While in that position, he must continue to move with rapidity under the surface; and whenever he chooses to return to his former situation, he has nothing to do but to bend back his head, and he will immediately return to the surface.

It is very common for novices in the art of swimming to make use of corks or bladders to assist in keeping the body above water. Some have utterly condemned the use of these; Dr Franklin however allows that they may be of service for supporting the body while one is learning what is called the *stroke*, or that manner of drawing in and striking out the hands and feet that is necessary to produce progressive motion. "But," says he, "you will be no swimmer till you can place confidence in the power of the water to support you: I would therefore advise the acquiring that confidence in the first place, especially as I have known several who, by a little of the practice necessary for that purpose, have insensibly acquired the stroke, taught as it were by nature.

and of a quiring confiden

"The practice I mean is this. Choosing a place where the water deepens gradually, walk coolly into it till it is up to your breast: then turn round your face to the shore, and throw an egg into the water, between you and the shore; it will sink to the bottom, and be easily seen there if the water is clear. It must lie in the water so deep as that you cannot reach it to take it up but by diving for it. To encourage yourself in order to do this, reflect that your progress will be from deeper to shallower water; and that at any time you may, by bringing your legs under you, and standing on the bottom, raise your head far above the water: then plunge under it with your eyes open, throwing yourself toward the egg, and endeavouring, by the action of your hands and feet against the water, to get forward till within reach of it. In this attempt you will find that the water buoys you up against your inclination; and it is not so easy a thing to sink as you imagined; that you cannot but by active force get down to the egg. Thus you feel the power of the water to support you, and learn to confide in that power; while your endeavours to overcome it, and to reach the egg, teach you the manner of acting on the water with your feet and hands; which action is afterwards used in swimming to support your head higher above water, or to go forward through it."

Swimming a pleasant and useful exercise.

As swimming is a healthy exercise and a pleasant amusement, and as a dexterity in it may frequently put it in a man's power to save his own life and the lives of his fellow-creatures, perhaps of his dearest friends, it can neither be useless nor uninteresting to consider a few of the evolutions which a swimmer must be master of, that he move in any direction without difficulty, without danger, and without being unnecessarily fatigued.

How to turn to the right or left.

There are several different ways of turning one's self in swimming. You may do it in this way: turn the palm of the right hand outwards, extend the arm in the same manner, and make a contrary movement with the left hand and left arm; then, by a gradual motion, incline your head and whole body to the left side, and the evolution will be finished. There is another way, which is easier still. Bend your head and body toward that side to which you are going to turn. If you wish to turn to the left, incline the thumb and the right hand toward the bottom, bend the fingers of the right hand, stretch it out, and use it for driving away the water sidewise, or, which is the same thing, for pushing yourself the contrary way. At the same time, with your left hand, the fingers being close, push the water behind you, and all at once turn your body and your face to the left, and the manœuvre will be accomplished. If you wish to turn to the right, you must do with your right hand what you did with your left, and with your left what you did with your right. You must be careful when turning yourself never to stretch out your legs, and be sure that the water be so deep that you be in no danger of hurting yourself.

How to turn from the belly to the back.

When you are swimming on your belly, and wish to turn on your back, draw your feet in quickly, and throw them before you; stretch out your hands behind you, and keep your body firm and steady. When you wish to turn from swimming on your back, fold your feet at once under your body, as if you were throwing them to the bottom, and at the same instant dart your body forwards, that you may fall upon your belly.

The eyes ought to be turned towards heaven.

In swimming, the eyes ought to be turned towards heaven. This is a most important rule, and to the neglect of it many of the accidents which befall swimmers are owing. For when they bend their eyes downwards, they insensibly bend their head too, and thus the mouth being too deep in the water, may admit a quantity of it in breaking; besides, the more the body is stretched, it covers a greater part of the surface of the water, and consequently its specific gravity is less. Any person who will make the experiment will find it impossible to dive while he keeps his head erect and his eyes fixed on the heavens.[1]

How to swim on the back,

The easiest posture in swimming is lying on the back. When you wish to swim in this posture, lay yourself softly on your back, and raise your breast to the surface of the water, keeping your body extended in the same line. Put your hands easily over the upper part of your thighs, and throw out your legs and draw them in alternately, keeping them within two feet of the surface. In this way you may advance in any direction you please. You may perhaps not like having so much of your head under water; there is, however, no way of swimming so easy, so safe, and so little fatiguing. If you wish to swim with great rapidity, you may use your arms as well as your feet; and you will find this the easiest way of breaking the force of the waves.

and advance forward.

In swimming on the back, one may advance forward as well as backward. For this purpose the body must be kept straight and extended; the breast inflated, so that the hollow of the back may assume a semicircular form. The hands must recline over the upper parts of the thighs. It is also necessary to raise the legs one after another, and draw them in strongly towards the hams, and then leave them suspended in the water. This way of swimming is not only pleasant, but may serve to rest you when fatigued.

How to swim on one side.

When you are tired with swimming on your back and belly, you may swim on one side. When you wish to do this, sink a little your left side and raise your right; you will immediately find yourself on your left side. Move then your left hand without either raising or sinking it; you have only to stretch it and draw it back, as in a straight line, on the surface of the water. Independently of the pleasure which this kind of motion will give you, you will have the satisfaction of seeing both sides of the river.

How to swim on the belly without the assistance of the hands.

It is possible to swim on the belly without the assistance of the hands. For this purpose you must keep your breast erect, your neck straight, and fix your hands behind your head, or upon your back, while you move forward by employing your feet. This way is not without its advantages. It is an excellent resource when the arms are seized with a cramp, or with any indisposition which makes it painful to exert them. This in some cases may be preferable to swimming on the back; for while in that attitude, one cannot see before them without turning every instant. If one of your legs be seized with a cramp, take hold of it with the hand opposite to it, and use the other hand and leg to advance or support yourself.

How to swim with the hands joined.

A very ancient and graceful mode of swimming, is that of swimming with the hands joined. When you wish to put this in practice, join your hands, keeping the thumbs and fingers towards heaven, so that they may appear above the water; then draw them back and push them forwards alternately from your breast. This method of swimming may be useful in several circumstances, but above all if you are entangled with grass or weeds. Your hands will then open a passage for you.

With the hands elevated.

As a person may sometimes have occasion to carry something in his hand in swimming, which he is anxious to preserve from the water, he may swim easily with one hand and hold a parcel in the other, as Cæsar swam with his Commentaries at Alexandria; or one may swim with both hands elevated. To perform this well, the swimmer must raise his breast, and keep it as much inflated as he can, at the same time that he supports the arms above the water. It must not be concealed that this method of swimming is attended with some danger to one who is not dexterous at the art; for if one should imprudently draw in his breast when his arms are raised, he would immediately sink to the bottom.

---

[1] An interesting question occurs here, which deserves to be considered. Since the body, when spread upon the surface, can be supported with so little exertion, and frequently without any at all, as in swimming on the back, how comes it to pass that a person when drowned sinks and frequently rises again some time afterwards. The reason is this. In the act of drowning, the lungs are filled with water, and consequently the body, being specifically heavier, sinks. It is well known that the human body contains a great quantity of air. This air is at first compressed by the water; and while this is the case, the body remains at the bottom; but as soon as the air by its elasticity endeavours to disengage itself from the compression, the body is swelled and expanded, becomes specifically lighter than the water, and consequently rises to the top.

How to rise to the surface after diving.

When a man plunges into the water, and has reached the bottom, he has only to give a small stroke with his foot against the ground in order to rise; but an experienced swimmer, if he misses the ground, has recourse to another expedient, which is very pretty, and which has not been much considered. Suppose him at a considerable depth, when he perceives that he cannot reach the bottom. In such a case, he first puts his hands before his face, at the height of his forehead, with the palms turned outwardly; then holding the fore part of his arm vertically, he makes them move backwards and forwards from right to left; that is to say, these two parts of his arms, having the elbow as a kind of pivot, describe very quickly, both the hands being open and the fingers joined, two small portions of a circle before the forehead, as if he would make the water retire, which he in fact does; and from these strokes given to the water, there results an oblique force, one part of which carries the swimmer upwards.

SWINDON, a town of the hundred of Kingsbridge in Wiltshire, eighty-three miles from London. It is a neat, well-built town, with a market on Monday, and several fairs. The inhabitants amounted in 1811 to 1341, in 1821 to 1580, and in 1831 to 1742.

SWINESHEAD, a town in the hundred of Kirton and county of Lincoln, 120 miles from London. It is a place of inconsiderable trade, with a market on Thursday. The inhabitants amounted in 1811 to 1561, in 1821 to 1696, and in 1831 to 1994.

SWITZERLAND.

Ancient history.

Switzerland is situate in western Europe, having France on the west, Germany on the north, Austria on the east and south-east, and Savoy and Piedmont on the south-west. This country was anciently called Helvetia, from its first known inhabitants: its more modern name is supposed to be derived from the canton of Schwytz, the cradle of Swiss independence. Little is known of the inhabitants of Switzerland till about one hundred years before Christ, when the Cimbri, a race of barbarians inhabiting the northern regions now known as Friesland and Sweden, crossed the Rhine and extended their conquests into Gaul. Several of the Helvetian tribes, tempted by the immense spoils gained by the Cimbri, entered into an alliance with them, and carried their united ravages nearly to the mouths of the Rhone. In this extremity the Gauls applied for assistance to the Romans, who speedily sent a powerful army to their assistance, under the command of the consul Lucius Cassius. This force, however, was suddenly attacked on the banks of the lake of Geneva, by the Tigurini, a tribe of the Helvetii, led by a young general named Divico. The Romans were totally defeated, the consul and his lieutenant Piso left dead on the field, and the survivors only permitted to retreat after they had given hostages and marched under the yoke. Emboldened by this success, Divico rejoined the Cimbri, and with their united forces crossed the Alps and entered Italy itself, where, however, they were defeated by Marius with tremendous slaughter, and the few who escaped sought refuge among the fastnesses of the Helvetian mountains.

For nearly half a century after this decisive defeat, the Helvetii confined themselves to their own country. But the recollection of the rich pastures and fertile plains of Gaul outlived the terror of the Roman arms, and made them resolve once more to quit their rocky fastnesses. After spending three years in preparation, they set out with their wives and families, cattle and possessions, led by the same Divico who had commanded their fathers fifty years before. The number who marched out on this expedition is computed at 368,000 souls, of whom 92,000 were able-bodied warriors.

The Helvetii defeated by Cæsar.

The Roman province of Gaul was at that time under the government of Julius Cæsar, and that consummate general no sooner heard of the emigration of the Helvetians than he took effectual measures to defeat their plans. After some abortive attempts at negociation, he attacked and defeated them in two engagements with tremendous slaughter. Their strength and spirit were completely broken, and, overwhelmed with shame and grief, their numbers reduced to scarcely 110,000, they returned to their desolated country and rebuilt their ruined habitations. In order to watch and overawe them, Cæsar erected a fortress at Noviodunum (Nyon), on the banks of the lake of Geneva, and established several other garrisons in different parts of the country.

Helvetia subjected by the Romans;

The Helvetii were at first the allies of the Roman people, but in the reign of Augustus they were reduced to complete subjection, and their country remained in the condition of a Roman province for upwards of three centuries, and underwent various reverses of fortune, according to the prosperous or adverse fortune of the empire to which it was subject. When the innumerable swarms of barbarians issuing from the unknown regions of the north and east overran Italy and destroyed the Roman empire, Switzerland also became their prey. The Goths established themselves in that portion of the country which bordered on Italy; the Burgundians fixed their residence on both sides of the Jura, on the lake of Geneva, and in the lower Valais, as far as the Aar; and the Allemanni took possession of the country to the eastward of that country, and of great part of Germany.

and by th Franks.

After this state of affairs had continued about a century, a new swarm of adventurers obtained the ascendency. These were the Franks, another German race, who, after traversing the Netherlands, gained possession of the whole of Gaul, and pouring their resistless myriads into Switzerland, forcibly dispossessed the inhabitants, and at length, after various changes, succeeded in obtaining exclusive dominion over the whole of Rhætia and Helvetia. Rhætia and the country between the lake of Constance and the Rhine, the Aar and St Gothard, in which German was the current language, were united to Suabia, while Geneva, the Valais, Neuchâtel, and the present country of Berne, Soleure, Freyburg, and Vaud, the districts in which Romance was the prevailing language, were united to Savoy, under the denomination of Little Burgundy. The Franks introduced into Helvetia the feudal system and other peculiar institutions and laws of the Germanic tribes. To them also the inhabitants were indebted for the blessings of the Christian religion, which contributed powerfully to the progress of civilization, and the revival of the country from its waste and desolate state. Switzerland remained subject to the Franks till after the death of Charlemagne, when, in consequence of the feuds of that monarch's successors, the vast empire which he had founded was entirely dismembered, and Switzerland was portioned out among France, Italy, and Germany. But this arrangement was of short duration, for the disorders and confusion produced by the continued wars enabled the provincial governors to throw off all allegiance to their feudal superiors, or to secure real independence while yielding nominal obedience. Switzerland was thus divided into a great number of petty states, generally engaged in hostilities with each other, and seldom uniting among themselves unless when menaced by some great and common danger. Such a case presented itself in the reign

Divided i to petty states.

of the emperor Henry I. surnamed the Fowler. An immense horde of barbarians, known by the name of Hungarians, issued from the east and the shores of the Black Sea, and overran Italy and Germany, burning and destroying wherever they came. In order to protect the inhabitants from the fury of these ruthless invaders, Henry built walls around a number of defensible places, to which all, in case of need, might fly for the security of their lives and property. In this manner Zürich, St Gall, Basel, and various other places, rose from petty hamlets to towns of considerable strength and numerous population. About the same period the bailifs of the emperor built and fortified Berne, Freyburg, and various other towns. A ninth of the free and nobler class of inhabitants were required to occupy these national fortresses, and they received the same political organization and rights as the more ancient cities of Germany. This was the first foundation of the class of burghers, who in process of time came to be a third estate in the kingdom. In proportion as the wealth and importance of the towns augmented, the citizens were eager to extend their rights and privileges. They availed themselves of every opportunity to purchase their emancipation from the feudal dominion of the bishops, abbots, and monasteries, to whose authority they had long been subjected; and in a short time the burghers were able to bid defiance to the nobles, and even to balance the political weight of the clergy.

Subject to the house of Austria.

The affairs of Switzerland continued in this state without any material alteration until the year 1290, when Rudolp of Hapsburg, whose castle was situated in the canton of the Aar, and who, besides possessing manorial rights and great influence in Schwytz, had held the office of imperial bailif of several towns, was elected emperor of Germany. This prince, though inhabiting a distant country, continued throughout his life to be strongly attached to Switzerland. He conferred new honours on its nobles, and granted additional privileges to its towns, or confirmed those which they already enjoyed. Rudolp was succeeded by his son Albert, whose ambition and rapacity soon alienated the affections of both his German and his Swiss subjects. Two of the imperial bailifs, Herman Gessler and Beringuer of Landenberg, who were appointed over the Waldstätten (the three cantons of Schwytz, Unterwalden, and Uri), subjected the inhabitants to every species of insolence and oppression. Gessler, in particular, was guilty of so many acts of wanton cruelty that he was at length put to death by the famous William Tell, who thus paved the way for the deliverance of his countrymen. Three patriots, whose names are still revered throughout the republic, Werner from the canton of Schwytz, Walter Hurst from Uri, and Arnold from Unterwalden, formed a conspiracy against the Austrian governors; and their measures were concerted with such wisdom, and executed with so much courage and intrepidity, that they obtained possession of every fortress of any considerable strength or importance. The three cantons formerly mentioned having thus achieved their independence, held a meeting on the 7th of January 1315, and laid the foundation of the Swiss confederation. Shortly after this revolt of the forest cantons, the emperor Albert was murdered by his nephew and some other nobles; but his son Duke Leopold marched against the cantons with a powerful army. The Schwytzers waited his arrival at Morgarten, on the slope of the mountain Sattel, and, notwithstanding the disparity of their forces, routed the Austrians with great slaughter; and it was with no small difficulty that the duke himself escaped, leaving most of his officers and an immense number of his soldiers dead upon the field.

The Swiss revolt from the Austrians, A. D. 1315.

In 1332 the inhabitants of Lucerne formed a perpetual league with the Waldstätten; and in 1351 the citizens of Zürich, having thrown off the yoke of the aristocracy, joined the Swiss republic, and on account of the power and wealth of the town it was promoted to the chief rank. Zug joined the confederation in 1352, and Berne in the following year. To the latter, in consideration of its importance, was assigned the second place of precedence.

Duke Leopold III. of Austria viewed the extending confederation with jealousy and alarm, and various quarrels having taken place between him and the cantons, hostilities were at length commenced. The duke, with a numerous force, chiefly composed of cavalry, marched rapidly towards the interior of the country, and on the 9th of July 1386 encountered the Swiss in the neighbourhood of Sempech. The battle was long and fiercely contested, but at length the Swiss patriots gained a complete victory; the duke himself was slain, and more than 600 of the higher and lower nobility, with about 2000 of their less distinguished adherents, were left dead on the field.

Defeat Leopold, A. D. 1386.

Two years after the battle of Sempech, the Austrians stormed Naefels, a small town in the canton of Glaris. The garrison retreated from the town as far as Mount Rute, where they took up a strong position, and awaited the approach of the enemy. The Austrians maintained the fight for some time with great ardour, but were in the end overthrown and put to flight. The bridge of Weser was broken down by the weight of the fugitives, and above 3000 common soldiers, and 183 knights, were slain in the battle, or drowned in the lake and in the river. These defeats induced Duke Leopold IV. to enter into a truce with the cantons for seven years, during which the Swiss contrived by various means to extend their territory and to increase their power.

Again defeat the Austrians, A. D. 1388.

With the exception of the disputes which took place between the people of the canton Appenzell, and of the Valais and Rhætian Alps, with their lords, and of the civil war which arose between Zürich and Schwytz relative to the right to some lands, no event of much importance occurred in the history of Switzerland till the year 1474, when Louis XI. of France induced the Swiss to make a diversion in his favour, by falling on the territory of Charles the Bold, duke of Burgundy, who had advanced to the very walls of Paris, and threatened Louis with the loss of his throne. This unprovoked attack induced the duke to offer terms of peace to the king of France, and the emperor of Germany, with whom he was at the same time at war; and these monarchs accepted his offer, leaving their late allies to meet his whole vengeance as they best might. Peace was no sooner concluded, than Charles determined to inflict condign punishment on them for their unjustifiable aggression, and in the spring of 1476 crossed the Jura with an army of sixty thousand men. He encountered the army of the confederates near the town of Grandson, and after a desperate conflict was totally defeated with the loss of a thousand men. His camp, with an immense booty, fell into the hands of the Swiss. A few months after, he was defeated, with prodigious slaughter, in a second action, near the little town of Morat; and two years later, when the duke was slain in the battle of Nancy, the Burgundians paid the confederates the sum of 150,000 florins to make peace with them.

Twice defeat the Duke of Burgundy.

These repeated victories procured for the Swiss the reputation of being the best soldiers in Europe; and a considerable number of them were hired to fight the battles of foreigners. The sudden wealth acquired by plunder and pensions excited its possessors to profusion and extravagance; their morals became corrupted, and the simple republican spirit almost disappeared. A spirit of cupidity and pride displayed itself among the rulers, and dissipation and love of plunder among the people; and the Swiss became notorious throughout Europe as the hirelings of any potentate who had battles to fight and gold to squander. Domestic troubles and feuds generally prevailed; the peace and security of the country were disturbed to such a degree by an armed and desperate banditti of disbanded soldiers and idle vagabonds, that in 1480, during the short space of three months, nearly 1500 assassins and robbers were condemned to death.

The confederation strengthened.
A. D. 1481.

The confederates had been faithfully supported in their wars by the towns of Freyburg and Soleure, and in 1481 these requested to be admitted into the confederation. Their request was warmly supported by the town cantons; but the mountaineers of the forest cantons objected to it, and the dispute ran so high, that at a general congress of all the confederates, the deputies were at the point of coming to blows, and the confederation was threatened with dissolution. This catastrophe was happily averted by the eloquent remonstrances of a pious hermit, called Nicholas Lavenbrugen. His simple but pathetic appeal had the effect of removing their differences, and Soleure and Freyburg were received into the Swiss confederation.

Independence of Switzerland acknowledged by the emperor.
A. D. 1499.

In the year 1497, the Grisons entered into a treaty offensive and defensive with the confederate cantons. This alliance gave great offence to the emperor Maximilian, who immediately collected his troops, and marched both against the Grisons and their Swiss allies. Battle after battle took place, in all of which the Austrians were defeated; and the emperor having lost 20,000 of his troops in eight months, and finding further exertions useless, concluded a peace with the Swiss at Basel in September 1499, by which he acknowledged their unconditional independence as a nation. This war, called the Suabian war, was the last the Swiss had to sustain for their independence. For three centuries after this date no farther attempts were made against the liberties of the Swiss cantons, which assumed their station as an independent power in Europe. The towns of Basel and Schaffhausen were received into the confederation in 1501, and Appenzell was added in 1513, and completed the number of thirteen cantons, which have constituted the Helvetic body till within our own times, namely, Zürich; Schwytz, Uri, Unterwalden, the three Waldstätten or forest cantons; Lucerne, Glaris, Zug, Berne, Freyburg, Soleure, Basel, Schaffhausen, and Appenzell. Besides these, there were various confederates and associates who were in alliance with the cantons, and entitled to assistance in case of foreign attack. These were the abbot of St Gall, the city of the same name, the towns of Mulhausen and Bienne, the Grisons and the Valais, the republic of Geneva, and the county of Neuchâtel.

Thirteen cantons.

Reformation.

Switzerland had scarcely obtained rest from her political wars, when religious disputes arose among the cantons, and converted into fierce enemies those who had lately fought side by side in defence of their liberties. The unscrupulous sale of indulgences by the agents of Pope Leo X. in Germany, Switzerland, and the other countries, led to a searching inquiry into the whole of the papal system, and caused vast multitudes to renounce altogether the authority of the church of Rome. In no country did the doctrines of the Reformation create a greater excitement, or meet with more zealous supporters, than in Switzerland. The inhabitants of Zürich, Berne, Schaff hausen, Basel, St Gall, and the Grisons, as well as of many parts in the neighbourhood of Geneva and Neuchâtel, eagerly adopted the opinions of Calvin and Zuinglius, while the people of the Waldstätten, and of Soleure and Freyburg, being more secluded and ignorant, and more under the control of the priests, continued staunch in their support of the papal authority. Fierce animosities speedily arose between the reformed and the popish cantons, and various sanguinary wars were carried on for many years. During these internal broils, the territory of the confederation was violated and their rights infringed without remonstrance; and such was the divided state of the cantons, that Austria, their ancient enemy, might easily have subdued them, but for the jealousy of the other great powers. To prevent this danger, they, in concluding the treaty of Westphalia in 1648, formally recognised the independence of the Swiss confederation. But though Switzerland was thus secured against the invasion of any of the greater powers, it continued to be torn by internal dissensions.

Insurrection of th peasants.

The arbitrary manner in which the large towns levied taxes upon the people of the country, and of the smaller towns and villages, caused great dissatisfaction, especially in the territories of Berne and Lucerne, and at length the peasantry rose up in rebellion against their rulers; and it was not until after considerable bloodshed that the revolt was quelled, and several of the chiefs who were taken alive were tried, condemned, and executed. Scarcely had this insurrection terminated when religious quarrels again broke out between the Protestants and the Romanists. Till near the close of the seventeenth century, Switzerland was distracted by the dissensions arising from this cause; and in 1703, the whole of the Protestant and of the Catholic cantons were openly arrayed against each other, and a civil war of several years' duration ensued. The immediate cause of the war was a quarrel between the people of Toggenburg and their superior the abbot of St Gall, who had endeavoured in a fraudulent manner to deprive them of their privileges. Zürich and Berne took part with the people, while the Catholic cantons espoused the cause of the abbot. Several battles were fought, and at length an army of Catholics, 12,000 in number, encountered 8000 Bernois at Villmergen. The conflict lasted six hours, and in the end the Catholics were completely routed, leaving 2000 of their number dead upon the field. A peace was soon after concluded on terms advantageous to the victors.

Civil war.
A. D. 170

From this period till towards the close of the eighteenth century, the state of Switzerland underwent no material alteration; and their internal discord paved the way for external aggression, and rendered them an easy prey to the grasping ambition of the French republic. In 1797, the French government, which had previously interfered in the affairs of Switzerland, manifested a determination to take possession of that country, and evidently sought for a pretence to come to an open rupture. The Swiss government placed their only hope in a passive neutrality, which in the end proved their ruin. For the sake of peace they submitted with the utmost servility to the imperious and insulting demands of the directory; but their humiliation did not save them from destruction. The emissaries of France laboured but too successfully to incite dissensions among the people, and the French rulers made these dissensions a pretext for their interference with the constitution of the country. In this way the bailiwicks of Valtelina, Chiavenna, and Bormio, which had been for centuries dependent on the Grisons, were incorporated with the Cisalpine republic. Insurrections broke out in several of the cantons, and were rendered triumphant by the assistance of the French arms. The inhabitants of Berne, Soleure, Freyburg, and especially of the Waldstätten, made a brave but ineffectual stand in defence of their rights and liberties. The most horrible excesses were committed by the French soldiers; the towns were successively rifled of their public property, and great part of the country was laid waste, and many of the inhabitants reduced to utter destitution. A new constitution was framed by the French directory, which provided that Switzerland should form a single republic, one and indivisible, under a central government to be established at Aarau. The country was divided into twenty-two cantons, and the supreme authority was committed to two councils and an executive directory, in whom was vested the appointment of prefects and other authorities for the various cantons, which were thus transformed into departments, with the loss of their independence as separate states. After this new constitution was established, a treaty was made with France, by one of the articles of which the Swiss republic was bound to furnish to its new ally a force of 18,000 men; and thus all the miseries of the conscription

Excesses of the French.

Independence of the republic.

Act of mediation. A. D. 1803.

were made familiar to the Swiss, as they had previously been to the French population. Great miseries were suffered by the people, from the excesses of every kind committed by the French troops, and their heavy requisitions and exactions. The small canton of Unterwalden refused to swear fidelity to the new constitution of the Helvetic republic, but after a desperate struggle it was subdued; the inhabitants were massacred without distinction of sex or age; and that district, once peaceful and happy, was left a scene of horrible desolation. During the campaign of 1799, Switzerland was the theatre of the struggle between the great powers of Austria, Russia, and France. The mountain cantons were in consequence utterly ruined, a considerable part of the country rendered uncultivated, and the population reduced to little short of actual starvation. The Helvetic directory was suppressed in 1800, and an executive commission substituted in its room; and about seven months after, this commission dissolved the councils and convoked a new legislature. A general diet was called in September 1801, for the purpose of re-organizing the constitution of the country. Meanwhile the treaty which was signed at Luneville between France and Austria, guaranteed the independence of the Helvetic republic, and the French troops were consequently ordered to evacuate Switzerland. Their departure was the signal for a general revolt. All the old factions were awakened afresh. The Pays de Vaud formed itself into a single republic; Uri, Schwytz, and Unterwalden took up arms against the Helvetian government; and the towns of Zürich, Basel, and Schaffhausen renounced their allegiance. A civil war appeared inevitable, when Napoleon Bonaparte offered himself as arbitrator between the contending parties, and ordered Marshal Ney to advance with a body of troops to the frontiers of Switzerland to enforce compliance with his mandates. The existing government was dissolved, a provisional government established, and deputies from all the cantons were ordered to assemble at Paris to deliberate upon a constitution for their country. Several months were spent in debates; and Napoleon, after he had heard and reflected on their representations, promulgated an act of mediation, which appears to have been drawn up with a view of reconciling opposite factions, and of fairly meeting various interests. It restored the old federative system, but introduced very considerable improvements. The act of mediation was promulgated 19th February 1803; and the Helvetic general government having been dissolved, and the new constitution put in force, the French troops finally evacuated the country.

New constitution. A. D. 1815.

From that time till 1814 Switzerland enjoyed internal peace; and during the gigantic wars which at that momentous period raged throughout Europe, this country rested in security amid the din of battles and the crash of falling empires, and made rapid progress in the arts of industry, and in the career of intellectual and social improvement. On the downfall of Napoleon the act of mediation was dissolved. The integrity of the country was guaranteed by the congress of Vienna in 1815. The territories formerly dependent on the bishop of Basel, which had been annexed to France, together with Valais, Neuchâtel, and Geneva, were ceded to it as new cantons, and a constitution, based on the act of mediation, was framed for the whole cantons, now amounting to twenty-two. On the 7th of August 1815 the federal compact was finally signed by all the deputies in the diet assembled at Zürich. The deputies then repaired in procession to the cathedral, where they bound themselves by a solemn oath, and in the name of their constituents, to the faithful observance of its enactments.

Recent history.

During the fifteen years which elapsed from 1815 to 1830, Switzerland enjoyed profound tranquillity. The general condition of the country was prosperous, and education was improved in several districts; but the civil and criminal laws remained in a defective state; the press was under a strict censorship, and various anomalies existed in the institutions of many of the cantons. Petitions were from time to time presented for the revision of the constitution of 1814, but were everywhere rejected by the councils. The first alteration of this state of things took place in the canton of Ticino in May and June 1830, and the example was speedily followed by all the other representative cantons of Switzerland. The new constitution established equality of political rights among all the citizens of the state; the direct system of electing all the members of the legislature, the elections to take place every four years; separation of the three powers, legislative, executive, and judicial; publicity of debates; liberty of the press, subject to fixed laws against libels; inviolability of person and property, and the right of petition. No tax can be imposed unless it is sanctioned by a majority of two thirds in the great council. The present constitution cannot be modified until twelve years shall have elapsed from its enactment, and then any alterations proposed in it must be submitted to the approval of the primary assemblies of the people. These alterations in their constitution were peaceably adopted by the most of the cantons; but in some of them popular tumults arose, which however were speedily suppressed by the firmness and prudence of the diet.

In 1834 the tranquillity of Switzerland was endangered by a considerable body of Polish, German, and Italian refugees, who had taken up their residence in Switzerland. In the month of January, some hundreds of these refugees made a sudden attack on the dominions of the king of Sardinia, in expectation of combined attacks and insurrections in other parts of the Sardinian monarchy. The Sardinian government made strong remonstrances to the confederation concerning this violation of the neutrality of the Swiss territory; and the courts of Austria, Prussia, and other German states, whose territories border on Switzerland, joined in these remonstrances. After some negociations, the matter was brought to an amicable termination by the Swiss governments promising in future to send away from their territory all those who should attempt to disturb the tranquillity of the states.

An attempt was made in the diet of 1832, and again in that of 1834, to procure a revision of the federal pact, but it terminated without any result. The last eight years have been years of severe trial for Switzerland, but she has safely passed through them, and has succeeded in maintaining both her internal tranquillity and her external independence.

Statistics. Extent.

Aspect of the country.

Mountains.

Switzerland lies between 45° 50′ and 47° 40′ north latitude, and 6° and 10° 30′ east longitude. Its extent from east to west is about 210 miles, and from north to south about 130 miles. Its area is estimated to contain about 11,000 square geographical miles. Switzerland forms part of the high land of central Europe. It rises above the plains of Lombardy on the south, and the plains of Dijon or Burgundy on the west. On the east it is connected by the Alps with the high lands of Tyrol and Bavaria, and on the north it adjoins the elevated plain of Suabia; from which it is separated only by the bed of the Rhine. It is bounded by mountains on the west, south-west, and east, but is open to the north on the side of Germany. The lower parts of Switzerland are generally more than 1200 feet above the level of the sea, and nearly 1000 feet higher than the plains of Lombardy, but the greater part of the surface is much higher. In point of romantic and picturesque scenery, Switzerland is reckoned the finest country in Europe. It is a singular assemblage of high mountains, deep valleys, rivers, and lakes. Two distinct ranges of mountains traverse Switzerland; the chain of the Jura, which stretches from south-west to north-east, and is about 240 or 250 miles in length, and from thirty-five to forty in breadth; and the chain of the Alps, which is much more extensive, and covers the greater part of the country with its numerous branches. The former occupies the western part of Switzerland, stretching from near the western extremity of the lake of Geneva along the boundary between France and the Pays de Vaud, and then enters the canton of Neuchâtel, which it almost entirely covers, as well as the north-west part of Berne and the greater part of Soleure and Basel, and the north-west part of Aargau. The range of the Jura is divided from the mountains of the Black Forest by the vale of the Rhine; and its eastern boundary is marked by the lakes of Neuchâtel and Bienne, and the valley of the Lower Aar from the confluence of the Thiele to the junction of the Aar with the Rhine. The Jura consists of several parallel ridges, of which the most eastern is generally the highest. It is precipitous and abrupt towards Switzerland, but becomes gradually lower on the side of France. It does not attain above one third of the height of the Alps, its principal summit in Switzerland being from 5500 to 5300 feet high, but in proportion to its height it is colder than the region of the Alps. The valleys formed by the Jura run parallel with the direction of the chain, are narrow and short, and some of them very elevated and cold. The Jura is principally formed by calcareous rocks of a grayish ash or bluish colour, and in some places mixed with marble.

The great chain of the Alps forms the highest part of the continent. The main ridge, called the Pennine Alps, forms the boundary between Switzerland and Italy, and separates the basin of the Upper Rhone on the north from that of the Po on the south. To the south of Mont Blanc the Alps consist of a single chain, with many lateral projections or spurs, chiefly on the west side. Eastward they are divided into two great ranges, which enclose the valley of the Upper Rhone, and meet at Mount St Gothard, which may be regarded as the centre of the Alpine system of Switzerland. Four ranges diverge from this point; the Bernese Alps to the west; the Alps of Glaris; and the northern Grisons to the north-east; the south-east branch, which forms the southern boundary of the Grisons on the side of Italy; and the south-west branch, which connects the St Gothard with the Pennine Alps. Between these ranges there are four large valleys, those of the Rhone, the Reuss, the Upper Rhine, and the Ticino. To the north-east of the group of St Gothard is the country of the Grisons, the whole surface of which is studded with elevated ridges and peaks. In this Alpine region there are not less than sixty deep valleys. The mean breadth of the highest portion of the Alps does not exceed 100 miles, but it widens considerably as they proceed eastward. (For an account of these mountain masses, their geology, climate, and natural history, see Alps.)

Table-land. North of the Alpine region and east of the Jura lies the table-land of Switzerland, which is the finest and most productive of the whole. It slopes from south to north, from the foot of the Alps to the Rhine and the lake of Constance, and includes the cantons of Vaud and Freyburg, the greater part of Berne, Lucerne, and Aargau, the whole of Zürich, Zug, Thurgau, and part of St Gall. The elevation of the table-land varies from 1200 to 1800 feet above the sea. Its surface is furrowed by numerous valleys, which generally run from south-east to north-west. Each of these valleys is divided by its river, and various ranges of wooded hills follow the course of the streams.

Rivers. The Rhine, the chief river of Switzerland, is formed by the streams which rise in the Alps of the Grisons, and receive the waters of all the glaciers of that lofty region. After leaving the country of the Grisons, it receives on its left bank the Tamina from the canton of St Gall, and on its right bank the Ill from the Austrian territory. It then flows through or rather forms the lakes of Constance and Untersee. On issuing from the latter, at the town of Stein, it flows in a general west direction, but by a tortuous course, as far as Basel, forming the natural boundary of Switzerland on the north side for a direct distance of about seventy miles. By means of the Thur, the Aar, and the Birs, it receives the waters of three fourths of Switzerland. At Basel the Rhine is about 500 feet broad; here it turns to the north, and soon after leaves the Swiss territory. The Rhone is formed by different streams from Mount Furca, at the north-eastern extremity of the Valais, at the height of 5500 feet above the sea. Descending rapidly to Oberwald, it proceeds in a south-west direction as far as Martigny, where it turns abruptly to the north-west, and continues in that course to its entrance into lake Leman. It issues out of this lake again at Geneva, below which it receives the Arve from the valley of Chamouny, and quits the Swiss territory near Chanci, the last village of the canton of Geneva. The Inn descends from Mount Bermina. The Adda rises from the base of Mount Gallo, and falls into the lake of Como. The Ticino issues from Mount Gries, and traverses the lake Maggiore in Italy. The Aar flows through the lakes of Brientz and Thun, and forms lofty cataracts before its junction with the Rhine. The Limmat, a rapid stream, which rises in the Alps of Glaris, flows through the lake of Wallerstadt: after marking the limits between the Schwytz and St Gall it forms the lake of Zürich, and, flowing through part of the cantons of Zürich and Aargau, enters the Aar below the confluence of the Reuss. The Thur rises in the mountains of High Toggenburg, in the canton of St Gall, and enters the Rhine below Rheinau.

Lakes. The Leman lake, or lake of Geneva, the great reservoir of the Rhone, spreads in the form of a crescent, its northern bank being about fifty-four miles in length, and its southern bank about forty-six. Its breadth near the middle is about nine miles, but it becomes much narrower towards Geneva. The surface of the lake is 1200 feet above the level of the sea. Its greatest depth is about 1800 feet, and its area 340 square miles. It receives several streams, the principal of which are the Dranse from the Alps of Savoy, and the Vevayse and Venoge from the Swiss side. Lake Leman is known to have been frozen over only twice, in A. D. 762 and 805. The lake of Constance, or Boden See, is about forty-five miles long and ten miles wide. Its area is about 290 square miles, and its greatest depth is 1800 feet. One or two steam-boats run upon the lake of Constance. The Waldstätten See, or lake of the four cantons, is about twenty-six miles in length. The southern part of it, called the lake of Uri, is a sheet of deep water, eight miles long and between one and two broad, running from south to north between two ranges of mountains almost perpendicular; a narrow channel unites it with the middle basin, which is about nine miles in length and about two wide. Another narrow strait leads from the middle into the western basin, called the lake of Lucerne, which is the widest and finest of the three. The lake is about 1400 feet above the level of the sea, and its greatest depth is 1000 feet. The country around the Waldstätten See is the cradle of Swiss independence, and is full of recollections of the exploits of its heroes. A steam-boat plies between Lucerne and Fluellen, the port of Altorf. The lake of Zürich, formed by the Limmat, is twenty-four miles long, and from one mile to two miles wide. Its greatest depth is 600 feet, and its surface is about 1300 feet above the level of the sea. A steam-boat plies on this lake between Zürich and Rapperswyl. The lake of Neuchâtel is about twenty-five miles in length, and five miles broad throughout one half of its length. It is about 1400 feet above the sea, and its greatest depth is about 350 feet. A steam-boat plies daily on this lake. Besides these there are several other lakes of considerable dimensions, such as the lake of Wallerstadt, formed by the Limmat, eleven miles in length, and the lakes of Brientz and Thun, both formed by the Aar; the latter thirteen miles long, its greatest depth 800 feet, and more than 1900 feet above the sea. A steam-boat plies on this lake, which is much visited by tourists from Berne. The fish which these lakes contain are pike, trout, salmon, lato, and umber, a very delicate fish, occasionally exported to Paris, and sold at a very high price.

inerals. The minerals and metals most abundant in Switzerland are porphyry, marble, and alabaster; iron, lead, zinc, cobalt, and bismuth. Arsenic and antimony are found in veins and in masses, rock-crystals are very common, sulphur is collected in many places, and particles of gold are found in the sands of some rivers, as the Rhine, the Aar, the Adda, and the Reuss; strata of bituminous wood are worked in several valleys, and the inhabitants use it for fuel.

ineral rings. Switzerland contains a greater number of mineral springs than any other country in Europe. The most frequented of these are the springs at Pfeffers and Leuk. The acidulated springs of St Maurice, in the canton of the Grisons, the baths of Gurnigel in Berne, and those at Baden, are also well known.

ifferent ces of in-abitants. Switzerland is the central point where three great European races and languages meet, and is not more remarkable for the variety of its physical features, than for the moral and religious diversities of its population. The Deutsch or German Swiss occupy the cantons of Zürich, Lucerne, Uri, Schwytz, Unterwalden, Glaris, Zug, Appenzell, St Gall, Thurgau, Schaffhausen, and Aargau, a great part of Basel and Berne, a considerable portion of Soleure, Freyburg, Valais, and Grisons, some communes of the canton of Vaud, and the commune of Bosco in the canton of Ticino, forming about two thirds of the whole population of Switzerland. The French Swiss occupy the cantons of Neuchâtel and Geneva, nearly the whole of Vaud, part of Freyburg, Soleure, and Valais, and the Jura portions of Basel and Berne, and form about one fifth of the entire population. The Italian Swiss inhabit the canton of Ticino, some valleys of the Grisons, and a few places in the Valais. To these are to be added the Romans or Rhætians, who are found in small numbers in the Grisons, the Oberland, towards the sources of the Rhine, and the upper part of the Engardine. Their language more nearly resembles Latin, or ancient Roman, than that of their Italian neighbours.

Before 1798 Switzerland consisted of a confederation of states of three very different kinds: 1. Thirteen cantons; 2. the subjects or vassals of these cantons; and, 3. the allies of these cantons. The federal bond which united the various cantons and their allies was very loose. There was not in Switzerland any permanent sovereign body, or central government, or standing federal magistrate, equally acknowledged by all. No important question could be decided in the general diets, unless it had been previously debated and decided on in the councils of each of the cantons. The cantons were not even allied to all; the three forest cantons alone were allied to every one of the other cantons. The subjects of the Swiss were either subjects of certain particular cantons, or common bailiwicks subject to all the cantons. **opulation.** The whole population of the thirteen cantons at the close of last century was about 1,000,000; that of their subjects was about 250,000; and that of their associates and confederates, and the subjects of these confederates, amounted to nearly half a million more. Altogether the territory belonging to the Helvetic federal body contained a population of about 1,700,000.

Form of overn-nent. Switzerland now forms a confederation of twenty-two cantons, united for the defence of their common liberty and independence, and security against attacks from abroad, as well as for the preservation of order and tranquillity in the interior. They guarantee each other reciprocally their respective territories. For these purposes a contingent of troops is furnished by each canton when required, in the proportion of one to fifty of its population; and a pecuniary quota, for defraying the military and other general expenses of the confederacy, is paid by each canton in proportion to its property and resources. A war-fund is also formed to meet exigencies; and for this purpose a federal duty is levied on foreign goods imported into Switzerland which are not articles of first necessity. The diet fixes the tariff as well as the rates to be paid by each canton. **Army.** The united federal contingents of all the cantons, which must be disciplined and furnished with clothes and arms, ready to march when required, amount to about 34,000 men, and the reserve, in case of need, to as many more. The general affairs of the confederation are intrusted to a council or diet, composed of deputies from the cantons, who vote according to the instructions of their respective governments. Each canton has only one vote, although it may send more than one deputy to the diet. The diet meets for two successive years by turns, at the capital of each of the directing cantons of Lucerne, Zürich, and Berne, the burgomaster or avoyer of which acts as president for the turn, with the title of Landmann. The diet usually meets on the first Monday of July, at the capital of the directing canton, and has the power of making war and peace, alliances with foreign powers, appointing diplomatic agents, and disposing of the military force. The ordinary sessions of the diet last about five weeks. Before closing its yearly session, it gives its instructions to the directing canton, to which the management of the general affairs is intrusted when the diet is not sitting. The directing canton is assisted in its duties by a federal chancery, consisting of a chancellor and secretary, both appointed by the diet. An extraordinary meeting of the diet may be convoked by the directing canton, whenever urgent circumstances may require it, or simply on the demand of five cantons.

The provisions of the federal pact are liberal and equitable in their spirit. One of them states, that "the enjoyment of political rights can never in future be the exclusive privilege of any one class of citizens in any one canton. Free importation and exportation of provisions, or merchandise, or cattle, shall be allowed from one canton to another without any import or export duties. The property of chapters and convents which exist in several cantons is guaranteed, but at the same time it is liable to the public charges and taxes, like any other private property." It will be seen by the above statements that the federal government of Switzerland has, properly speaking, no permanent executive, and the diet is merely an assembly of delegates from the various cantons, who decide according to the instructions given by their respective governments. Many attempts have been made to give more influence to a central authority; but the resistance to any system of centralization and unity has been so strong, and the apprehensions of encroachments on the part of any general government upon the sovereign independent authority of the different cantons so widely spread, that all proposals for modifying the federal convention have hitherto failed. The independence of the different cantons has been singularly preserved. Revolutions which have completely changed the constitution and the laws of one district have had little or no influence upon another. The boundary of a canton has bounded the most marked and violent political commotions. Civil war itself has not spread beyond the narrow sphere of local interests. Though in the different cantons the inhabitants enjoy an almost absolute equality of rights and privileges, yet these advantages cease as soon as they pass the narrow local territory to which they belong; and the general character of a Swiss citizen has no immunities spreading over the whole of Switzerland.[1]

---

[1] Bowring's Report, p. 5.

Twenty-two cantons.

The constitutions of the twenty-two cantons may be ranged into three classes. The first class is that of the pure democracies, consisting of the old mountain cantons, Schwytz, Uri, Unterwalden, Glaris, Zug, and Appenzell. To these may be added the Grisons and the Valais, which at first were only allies of the Swiss, but are now integral parts of the confederation. The second class of cantons consists of those in which aristocratic privileges had been enjoyed for centuries by the principal town of the canton. These cantons are Zürich, Berne, Freyburg, Soleure, Lucerne, Basel, and Schaffhausen; but their constitutions underwent a thorough change in 1830, and the country districts were then admitted to the enjoyment of equal privileges with the towns. The third class is that of the new cantons formed since 1803, out of the former bailiwicks; namely, Aargau, Thurgau, Vaud, Ticino, and St Gall. The constitutions of these cantons were also rendered more popular in 1830, and framed on the principle of equality of rights among all classes of the citizens. Two cantons have not been enumerated in any of the above classes, Geneva and Neuchâtel. The institutions of the former at one time resembled those of the aristocratic cantons, but they have now been established on a popular basis. The latter is a constitutional monarchy, of which the king of Prussia is prince. In the representative cantons of Berne, Lucerne, Aargau, Ticino, and Geneva, a property qualification is required for members of the legislature.

Agriculture.

The different branches of agriculture are well understood in Switzerland. The extent and fertility of the pastures are favourable to the breeding of cattle. The oxen are remarkable for their size; and the cows, particularly the short-horned breed in the valleys of Gruyêres, are much prized in different countries. The horses are strong and hardy, but the mule is the most common beast of burden in the mountains. The central and south-eastern cantons are chiefly dependent on their agricultural productions.

Manufactures.

The commercial relations of Switzerland are of great importance, and her manufactures have gradually forced their way into all the markets of the world, however remote or seemingly inaccessible. This result is the more remarkable, as Switzerland neither produces the raw material which she manufactures, nor, when manufactured, has she any port of outlet, except on such conditions as her maritime neighbours impose upon her; and yet, in spite of these obstacles, her progress has been almost unexampled in manufacturing prosperity. Capital is rapidly increasing, through the influence of unrestricted industry. Activity is everywhere visible both in the trading and the agricultural districts. Wages are comparatively low in many of the departments of industry, the necessary result of the general cheapness of most of the articles of consumption; a cheapness which again is the cause and consequence of the free egress and ingress of all commodities. The land is for the most part released from tithes and taxes, and the people subject to very trifling fiscal burthens. The great secret of the commercial prosperity of Switzerland is,—industry has been left to itself. Capital has not been diverted by legislative interference from its natural tendencies. The consumer has been allowed to go to the cheapest market, the producer to the dearest; and the present position and prospects of Swiss industry furnish abundant evidence of the wisdom of this policy. The prohibitory system adopted by the surrounding states excited at first some alarm among the manufacturers of Switzerland; but their anxieties on this subject have now ceased, and the narrow policy of their neighbours has only had the effect of forcing the Swiss into a wider and more profitable field, which they have been able successfully to explore to the extent of their capitals and their means of production. Many of the manufacturers, who had formerly been strenuous advocates for heavy custom-house duties on foreign articles, are now convinced by experience that their views were erroneous.

The various forms of government in Switzerland have proved to some extent a cause of embarrassment and difficulty to her national commerce. No prohibition is laid by any of the states on the import, export, or transit of any article; but each canton maintains the right to stipulate the conditions of ingress and egress, and the transport of merchandise is necessarily impeded by the collection of tolls at the different frontiers. Many attempts have been made by the most intelligent merchants to equalize the transit-duty, and to remove the charges and embarrassments of so many local administrations, by some general plan; but as the tolls are one of the main sources of local revenue, the cantons have been unwilling to abandon them for any national and general object.

Foreign trade.

A very considerable amount of trade is carried on between France and Switzerland, the frontier territory being extensive, the language in those districts identical, and the customs of the adjacent provinces substantially the same. On an average of fourteen years the annual imports into France from Switzerland amount to L.454,345, the annual exports from France to Switzerland to L.1,094,554. The principal articles imported from France are wine, oil, madder, brandy, alcohol, salt, fruit, sugar, coffee, and colonial produce, silk, woollen, and cotton manufactures, and articles of fashion in great variety. There is no duty, except a nominal one, on any of these articles, while France receives from Switzerland some horned cattle and cheese, both of which pay enormous duties; and ribbands, linens, and threads, all subject to large custom-house imposts. There is also a considerable export of watches and jewellery, which is principally in the hands of contraband traders. The unfriendly and hostile tariff of France has naturally produced much discontent in Switzerland, while it is a notorious fact, that the protection afforded to French manufactures, by highly raised or prohibitory tariffs, has not produced its intended results; that no manufacturing industry has suffered such violent shocks, or seen such terrible reverses, as the industry of France.

The Prussian commercial league caused at its origin a considerable alarm, and appeared to menace Switzerland with a serious reduction of exports to Germany. But time and experience have diminished these apprehensions.

The imports from England are cast iron, steel, pewter, tin, fine hard ware, a small quantity of printed cottons, woollen stuffs, tea, pottery, India and China silk, dyeing ingredients, and colonial productions, when they are cheaper in England than in the continental ports of Europe. Switzerland, on the other hand, furnishes very few articles to England; and these principally consist of embroidered muslins, Turkey-red calicoes, and a few printed goods upon the same red ground.

After the peace of 1815, the Swiss merchants, finding themselves precluded, by the prohibitive system, from almost the whole of the European markets, directed their attention to the United States of America, and gradually extended their relations with the southern parts of that continent. Throughout the whole of that hemisphere, the consumption of their manufactures has increased from year to year. Besides this new market for the sale of their goods, they have made some experiments in the East Indies, and these have now acquired some importance. They have likewise a few consumers in the states of Barbary, Egypt, Illyria, Greece, Turkey, and Persia.

The Swiss cantons which are the most distinguished for their wealth and industry, and for their general prosperity, are Zürich, Basel, Geneva, St Gall, Neuchâtel, Appenzell, and Aargau. The canton of Appenzell has manufactories of muslins, cottons, and silks, and receives a considerable quantity of cotton yarns from England. Neuchâtel exports considerable quantities of wines and cheeses, and has very extensive manufactories of watches and jewellery, lace and printed cottons. Within these few years the making of sparkling wine has been greatly extended. The principal manufactures are watches, printed cottons, and lace. The probable production of printed cottons in Neuchâtel is now about 80,000 pieces per annum, each containing about thirty-two English yards. Watch-making is carried on to an immense and increasing extent in the mountainous districts of this canton, in the French portion of the canton of Berne, and in the town and neighbourhood of Geneva. It has been a source of wealth and comfort to many thousands of the inhabitants, who, in the remote villages of the Jura, have gathered around them a large portion of the enjoyments of life. Switzerland has long furnished the markets of France; and though the names of certain French watchmakers have obtained a European celebrity, yet an examination into this trade has elicited the fact, that not ten watches are made in Paris in the course of a year, the immense consumption of France being furnished from Switzerland, and the Swiss works being only examined and rectified by the French manufacturers. The contraband trade into France was immense, but they are now admitted into that country at six per cent. for gold, and ten per cent. for silver watches; and a considerable quantity pays regularly this moderate duty. The Jura Mountains have been the cradle of the most exquisite productions of the mechanical arts. During the winter, which lasts from six to seven months, the inhabitants are almost imprisoned in their dwellings, and occupy themselves in those works which require the utmost development of skilful ingenuity. Nearly 120,000 watches are produced annually in the elevated regions of Neuchâtel. The largest proportion of these is exported to the United States of America. It is not easy to state the exact number of workmen who are engaged in watchmaking, because nearly the whole of the population are more or less occupied in this branch of industry, which they carry on in their own houses and amidst their own families. The manufactures of Neuchâtel are admitted into Prussia on diminished duties. Watches and such articles pay only one half of the duty stipulated by the tariff.

The main source of the trade in the canton of Thurgau is the manufacture of cotton, flax, and silk, with their various establishments for weaving, printing, and dycing. The exports are principally wine, fruit, and cider, oats, brandy, linen, cattle, &c. The imports principally consist of iron, iron-wares, and metal manufactures, salt, woollen goods, fine cloths, sugar, coffee, chicory, madder, drugs, and dye-stuffs, tobacco, wheat, fine cotton yarns, &c.

The canton of Schaffhausen possesses a considerable transit trade, which is facilitated by the navigation of the Rhine. This canton has suffered more than any other from the Prussian commercial league, its principal export being wine, of which the German markets were the main seats of consumption. Nature has blessed this small district with a fertile soil, which places it in the class of the agricultural rather than that of the commercial cantons of Switzerland.

Basel is almost entirely a commercial and manufacturing territory; its industry is principally engaged in the production of ribbands and some silks. The former are exported to the value of about 10,000,000 of French francs. About one half of these goes to the United States, the remainder is sent to Germany, France, Holland, Denmark, Sweden, &c. Since 1814, and particularly within a few years, the progress of Basel has been very great, both as regards the quantity and the quality of its manufactures.

The manufactures of Zürich are of ancient date. The silk manufacture of this town dates as far back as the thirteenth century, and it still forms a very important article in the trade of this canton. The silk manufactures of Zürich consist of florentines, gros de Naples, gros de Berlin, marcelines, taffetas, serges, levantines, silk handkerchiefs, a few shawls, &c. The number of looms at present employed in the silk trade may be reckoned at 10,000; and the total annual produce of the silk manufacture of Zürich has been estimated at L.600,000 sterling. The silk manufacture of Switzerland is constantly increasing, and it is in the town and canton of Zürich that it is most extensively carried on. Great improvements have been made, and are constantly making, in this branch of industry. Zürich also possesses some cotton manufactures. About 800,000 pieces of cotton are manufactured yearly. The imports of Zürich consist mainly of cotton yarns from England, woollen cloths, bark, straw hats, linens, furs, glass, stationery, wheat principally from Suabia, wine from France, Neuchâtel, and Vaud, brandy, fruits, tobacco, fir-wood, cotton and silk, wool and colonial cattle, butter and cheese, minerals, &c.

The principal manufacture of Aargau is cotton in its various branches; the second in importance is that of silk. The exportation of these articles is principally to Italy, Piedmont, the northern states of Germany, Turkey, and North and South America. The principal articles of import are wheat, wine, salt, and leather, iron and other metals, hard ware, tobacco and snuff, hemp and flax, chicory, oil, raw cotton, cotton twist, fine cotton manufactures from England, woollen cloths, raw silk, spices, drugs, dye-stuffs, dry goods, indigo, &c.

The canton of Geneva, for its small extent of surface, presents a remarkable scene of manufacturing industry. Jewellery, watches, and musical boxes, are three of the most important branches of trade, employing a great number of hands, and imparting the utmost activity to a commerce which conveys these productions to all quarters of the globe. The watchmakers of Great Britain buy largely both in Geneva and Neuchâtel. The average annual export to England is from 8000 to 10,000 watches, and the average price about L.10 sterling. The jewellery sent from Geneva to England represents a value of about L.60,000 per annum. In an article of such small bulk as a watch, it has been found impossible to guard against illicit introduction; the contraband trade is consequently very large, and scarcely a single watch pays the duty of twenty-five per cent. The smuggling is carried on almost wholly by French houses, who reap the profits of the smuggling premium, and who, it appears by the small amount of seizures, really run scarcely any risk. The English consumer pays the gains of the French smuggler, and pays too for that damage, delay, and risk which accompany fraudulent transactions. Of other sorts of merchandise Geneva exports annually about 120,000 quintals. The amount of British manufactures sold in the canton is estimated at about L.200,000 per annum. One half of this is supposed to be consumed in the town and neighbourhood, the other half is smuggled into France.

Labouring classes.

There are several striking peculiarities in the condition and employments of the labouring classes of Switzerland. There are few weaving factories or buildings in which the labouring weavers are congregated together. Their looms are in their own abodes, which are scattered over the country. They receive from the manufacturer the chain and the woof, and return to him the woven article. Weaving can hardly indeed be called a manufacturing industry; it is a sort of domestic labour, associated with, and often subordinate to, agricultural employment. It is in fact but one of two means of existence, the labouring population being only in part dependent on it. It is very common to find many looms in the cottage of a small farming labourer, the whole of which may be worked by its members when the weather, or the seasons, or other circumstances, withdraw them from the field. In the common apartment of the family of the country people, one or two members of the family may be seen weaving, and carrying on at the same time their household occupation; sometimes working in their gardens, and contributing in turns their assistance in the cultivation of their fields, and the labour of agriculture in general. The quality and neatness of the articles produced are evidently rendered inferior by this custom; but, on the other hand, it is more economical, and during a slackness of trade the workman who possesses a garden and a little ground suffers less. In almost every part of Switzerland, with the exception of those mountain heights which are incapable of cultivation, agricultural labour affords resources when wages fall or markets are glutted, so that the pressure of want is generally light and temporary.

The working classes in Switzerland are divided into four different sections, viz. manufacturers, weavers, winders, and embroiderers. There are manufacturers of every order and description, from the individual who only manufactures the quantity which himself and his family can weave, up to those who employ a hundred weavers or embroiderers; for the manufacturer who employs embroiderers does not engage in weaving. These manufacturers, who either sell their goods unbleached to the traders at home, or bleached to foreigners, breakfast upon coffee and milk, butter, honey, or green cheese. Their dinner is composed of soup and bouilli, potatoes, or porridge. Their beverage is cider or milk. Many of them sup upon coffee, and they seldom drink wine. This class is in general very economical. They take a great interest in public affairs, and pride themselves particularly upon their probity and honour. They furnish the greatest number of magistrates, and from among them are principally chosen all the parochial authorities.

The weaver, as soon as it is possible for him to do so, purchases a piece of ground, or at least a small house; and very frequently the manufacturer furnishes him with the means. The acquisition of landed property is greatly promoted in Switzerland, by the facility with which money may be borrowed upon mortgage. This class of working proprietors forms the great mass of voters in the popular assemblies.

Rate of wages.

All the weavers in Switzerland make use of coffee, milk, oatmeal, and potatoes, which compose their principal food. They work from thirteen to fourteen hours a day. They earn from 1s. 10d. to 9s. 2d. a week; but the greatest number only earn from 3s. 8d. to 5s. per week. The winders, many of whom are old people of both sexes, earn from 1d. to 3d. sterling a day. The embroiderers, who are generally women or young lads, earn on an average about 6½d. a day. In Neuchâtel the ordinary rate of wages is, for male domestics, from L.8 to L.12 sterling, and for females, from L.4 to L.6 sterling, per annum. The average wages of agricultural labourers are from 1s. 1d. to 1s. 8d. per day. The wages of artisans vary extremely, the lowest being about 9d. and the highest 11d. per day. The wages of watchmakers may be calculated at from L.55. 10s. to L.83. 5s. per annum; but workmen are generally paid by the job.

Price of provisions.

Provisions are very cheap in Switzerland. In the canton of Appenzell, a pound of bread weighing 20 ounces is worth 4 kreutzers, rather less than 1½d. In Neuchâtel, the loaf of white bread is from 2d. to 2½d.; meat, from 4d. to 5¼d.; butter, from 9½d. to 10d. the pound of 17 ounces. The measure of potatoes weighing from 33 to 34 pounds, is worth from 10d. to 1s. 1¼d.; milk, 1¼d.; and wine from 3d. to 6d. the bottle.

Clergy.

In Switzerland the clergy are supported by the state. The cost of the church establishment in Zürich is L.8000 per annum, being 9d. for each individual. The clergy amount to 271. In Neuchâtel the maximum salary of a clergyman is L.121, the minimum L.72, and the average L.83. There are 34 clergymen in this canton, which gives one to every 1647 persons. The Protestant religion is professed by the cantons of Basel, Berne, Vaud, Schaffhausen, Zürich, Geneva, and Neuchâtel. Soleure, Freyburg, Lucerne, Zug, Schwytz, Unterwalden, Uri, Ticino, and Valais, have continued Romanists. The cantons of Aargau, Glaris, Thurgau, St Gall, Appenzell, and the Grisons, contain a mixture of Romanists and Protestants.

Education.

Education is very generally diffused throughout Switzerland. In Appenzell every one is instructed; and for many years past the law does not allow any person to be admitted to the sacrament who cannot read; and the greater part of the population can also write, and have acquired the rudiments of arithmetic and singing. In Neuchâtel a considerable sum is paid by the state for the purpose of education. Every commune is required to provide a schoolmaster, and education is made obligatory throughout the principality. There is no person under the age of forty who is unable to read and write; and it is extremely difficult to find a person who does not also know how to calculate, and who is not well acquainted with his civil and political rights. To religious instruction much attention is paid. Before being admitted to the sacrament, the young men are obliged to attend for a certain number of years on the public ordinances, as well as to receive private lessons from their own pastors. In Basel both the primary and superior schools are good; and for many years the poor have been obliged to send their children to school for a course of elementary instruction, which occupies them until their tenth or twelfth year. The means for educating them are furnished by the poor-fund. In this manner children are prevented from entering too young into the factories, or from being employed in too laborious occupations.

At Hofwyl, in the canton of Berne, the establishments of Mr de Fellenberg for the maintenance and education of poor children, and his institution for the instruction of schoolmasters, have been attended with that success which might have been expected from efforts prompted by pure benevolence and guided by sound judgment.

In Aargau every district of 120 children must have at least one primary and one superior school. In every circle, the population being from 15,000 to 20,000 souls, there are from five to six secondary schools, and in the capital a gymnasium and a school of art. Besides this, there is a normal school for the instruction of teachers. The cost of these establishments is paid partly by the communes, and partly from the state funds. In Thurgau, every child, on reaching the age of five years, must be sent to school. Of the whole proceeds of the land-tax, two fifths have been applied to the purposes of education. A model-school for the education of teachers, established at Krutzlingen in 1833, under the superintendence of Mr Wehrlea, a pupil of Fellenberg, has had great success. Funds are cheerfully and liberally voted by the legislature. In 1834 more than one fifth of the whole population was attending the schools.

Poor-laws.

The poor in Switzerland are supported by a poor-law, greatly assisted however by voluntary contributions. The general law is that each parish shall take care of its own poor, but the arrangements in the different parishes respecting paupers are very various.

Administration of justice.

The administration of justice in Switzerland is prompt and economical. In Neuchâtel, for example, a verdict obtained in the Court of First Instance, might be pressed through all its stages, even to the confiscation of property to any amount, at a cost of less than 6s. 8d. sterling, and with a delay of only three weeks, there being three stages of appeal, each one allowing of a week for appearance and answer. While the cost to suitors is small, the cost to the public is equally so. In the district of Valangin, consisting of 6104 souls, the expenses for the administration of civil justice for 1834 amounted to less than five sixths of a farthing per individual; yet there are 122 trusteeships of minors, lunatics, &c., committed to the charge of the civil tribunals. There are on an average seventy causes per annum, the average cost of which to the suitors was about 4s. 6d. per suit. The cost of the criminal tribunals of the same district was about L.140 sterling.

Taxes.

The taxes in Switzerland are extremely light. In Neuchâtel they amount on an average to about 4s. 8d. per inhabitant yearly; in Aargau, to 2s. 6d.; in the canton of Vaud, to 4s. 8d. The whole amount of taxes paid per individual in Thurgau, is not more than one fifth of what is paid in England per individual for the poor-rates alone. In Zürich the poor-rates are less than 2½d. per annum for each inhabitant. The civil expenditure is little more than 10d. and the military expenses less than 6d. for each.

Savings banks.

Savings banks are very generally established in Switzerland, but the working classes seldom deposit in them any of their earnings. They are principally made use of by the children, for whom their parents deposit their savings, in order to purchase for them an equipment when their first attendance at the Lord's Supper gives them the rights of citizens. Servants and artists also place their savings in these banks; but the ambition of the workmen is to invest the fruits of their economy in the acquisition of a house, or of a small portion of land.

Population.

In 1817 the population of Switzerland amounted to 1,687,900, in 1827 to 1,916,000, in 1836 to 2,177,420, of whom 130,500 were Protestants, 870,000 Roman Catholics, about 3000 Jews, and a few Moravians and Anabaptists. German is spoken by about 1,560,000 people, French by 450,000, Italian by 124,000, Rumonsch and Ladin by about 42,000 in the Grisons. The following table exhibits an account of the population, &c. in 1838. (B. Q.)

Cantons.	Area in Square Geographical Miles.	Citizens of the Cantons.	Citizens of other Cantons.	Strangers.	Total Population. 1838.	Roman Catholics.	Protestants.	Contingent to the		Capitals.

SWORD, an offensive weapon worn at the side, and serving either to cut or stab. Its parts are, the handle, guard, and blade; to which may be added the bow, scabbard, pummel, &c.

Sword of State, which is borne before the king, lords, and governors of counties, cities, or boroughs, &c. For or before the king, it ought to be carried upright; the hilt as low as the bearer's waist, the blade up between his eyes. For or before a duke, the blade must decline from the head, and be carried between the neck and the right shoulder. For or before an earl, the blade is to be carried between the point of the shoulder and the elbow; and for or before a baron, the blade is to be borne in the bend of the arm.

SYDABAD, a town of Hindustan, province of Agra, 20 miles south by east from the city of Agra. Long. 77. 57. E. Lat. 27. 30. N.

SYDAPORUM, a town of Hindustan, in the Carnatic, 90 miles N.N.W. from Madras. Long. 79. 45. E. Lat. 14. 11. N.

SYDENHAM, Thomas, an excellent English physician, was the son of William Sydenham of Winford Eagle, in Dorsetshire, and was born there about the year 1624. He studied at Magdalen Hall, Oxford, but left that university when Oxford was garrisoned for King Charles I., and went to London, where, becoming acquainted with Dr Cox, an eminent physician, that gentleman persuaded him to apply himself to the study of physic. Accordingly, after the garrison was delivered up to the parliament, he retired again to Magdalen Hall, entered on the study of medicine, and in 1648 was created bachelor of physic. He was soon afterwards made a fellow of All-Souls College, and continued there several years. On leaving the university he settled at Westminster, became doctor of his faculty at Cambridge, grew famous for his practice, and was the chief physician in London from the year 1660 to 1670, at which period he began to be disabled by the gout. He died in 1689. His works, written in the Latin language, are highly esteemed both at home and abroad. They have often been reprinted, and have been translated into various languages. Sydenham was famous for his cool regimen in the small pox, for giving the bark after the paroxysm in agues, and for his use of laudanum. He regulated his practice more by his own observations and inquiries, than by the method either of his predecessors or contemporaries.

---

[1] Switzerland being both a German and a French country, most of the principal places have both a German and a French name. Sometimes, however, there is also an Italian name, as *Bellinzona*; and some of them have even three forms, as *Chiavenna*, *Cleven*, *Cleves*, the first of which is the Italian, the second the German, and the third the French form of the same name.

SYDNEY, the capital of the British settlements in New South Wales, situated about seven miles from the mouth of Port Jackson, in a cove of the same name, which is a most capacious natural basin, having a depth of water to allow the approach of the largest ships to the very sides of the rocks, and being perfectly secure against any wind. Sydney Cove is formed by two ridges running out into the harbour; the one to the left terminating in Bennilong's Point, on the low extremity of which stands Fort Macquarrie, with its castellated martello towers; and that to the right in Dawe's Point, with a fort bearing that name, which in like manner occupies its extremity. Down the hollow between these ridges a small rill trickles slowly into the head of the cove, in the rocky sandstone bed of which tanks have been cut to retain the water during the summer droughts, which insures a supply during that dry season. Along this hollow, for upwards of a mile, in a westerly direction, extends the main thoroughfare, George Street, which all the other streets either run parallel to or intersect; the town thus occupying the whole of the hollow, and creeping up the gradual ascents on each side. Near the harbour, where the ground is valuable, the houses are usually contiguous; but, generally speaking, the better houses in Sydney are built in the cottage style, of white freestone, or of brick plastered and whitewashed, one or two stories high, with verandahs in front, and enclosed by a neat wooden paling lined occasionally with geranium hedges, and having generally a commodious garden behind. The streets are wide and well lighted. Until the administration of Governor Macquarrie, little or no attention had been paid to the laying out of the streets. He succeeded however, in establishing a more perfect regularity; and the town is now on the whole regularly built, and has a light and airy appearance. It contains the parish churches of St Philip and St George; also a Presbyterian kirk, a Methodist and a Catholic chapel, a male orphan school endowed by the government, and a benevolent asylum supported by individuals. It has two steam flour-mills, three water-mills, and four wind-mills in the immediate vicinity; while numerous breweries are scattered through the town. There are several hotels, which are elegant and well kept.

The ridge on the left is successively crowned by the lofty-looking buildings of the horse-barracks, the colonial hospital, the convict-barracks, and a fine Gothic Catholic chapel; beyond which lies the promenade of Hyde Park, flanked towards the town by a row of pretty cottages, and towards the country by a high brick-walled garden appertaining to the government. On the ridge to the right of the cove, rows rising above rows of neat white cottages are seen, overlooked by Fort Philip with its signal-post and telegraphic appendages; also in the same line the military hospital and wind-mill, St James's Church, the Gothic Presbyterian kirk; and beyond these the military barracks, forming three fourths of a large square, and opening to George Street with an extensive green plot in the centre for the purposes of parade. The convict-hospital, with the officers' apartments and store-rooms, perched upon the most prominent ridge to the left of the cove, consists of three two-story buildings of freestone ranged in a line, and surrounded by a high wall. At the colonial dock-yard on the right of the cove, all the government-vessels load and unload, and are repaired. The timber-yard is a range of workshops forming a square to the left of George Street, near the guard-house, where are employed the government carpenters, blacksmiths, and other mechanics. A few hundred yards from the head of the cove, towards the left, stands the governor's house, with its beautiful domain in front ornamented by large trees of the finest foliage, with a fine shrubbery in the back-ground; the whole occupying a space from beyond the head of the cove to near Bennilong's Point. Between the domain and the cove an agreeable walk has been formed, chiefly in the solid rock, which has become a favourite Sunday walk. A commodious market-house stands upon the right of George Street, beyond the military barracks, which is abundantly supplied with provisions of every description, with butcher-meat and poultry, besides maize, wheat, potatoes, pease, carrots, turnips, cabbages, and fruit. Fish are also abundant, being caught with hooks and lines by the natives, and disposed of to retailers. Oysters abound on all the tide-rocks, and are sold at a shilling a quart. Crayfish, lobsters, and prawns are commonly found, while the little bays swarm with crabs. The whole is placed under the charge of the clerk of the market, under whose authority good order is maintained. On the market-days all kinds of showy wares are displayed for sale.

Sydney is divided into six police districts, with a lock-up-house, and a nightly watch, by whose vigilance great quietness is maintained. There are delightful promenades and drives in the vicinity of the town, and abundance of gigs and riding-horses may be hired at 15s. and 10s. a day. A four-horse coach runs twice a day, and a caravan once, between Sydney and Paramatta, a distance of fifteen miles; and another thrice a week to Liverpool, twenty-one miles; while a third proceeds from Paramatta to Windsor, twenty-three miles, three times a week. Sydney contains several good public schools for the youth of both sexes, and other seminaries for those more advanced, which are well attended to, and in which education may be obtained on reasonable terms. The population is rapidly increasing with the progress of the colony. About the year 1810 it amounted to 7000. The following is the census in 1836, as laid before parliament:—Males 9179, convicts 2932; females 7032, convicts 586; total, 19,729. Long. 151. 25. E. Lat. 33. 15. S. (F.)

SYENE, an ancient city of Egypt, situated, according to Mr Bruce, in north latitude 24° 0′ 45″. Pliny and Strabo both say that it lay directly under the tropic of Cancer. Syene is remarkable for being the place where the first attempt was made to measure the circumference of the earth. This was done by Eratosthenes, whom Ptolemy Euergetes had invited from Athens to Alexandria. In this attempt two positions were assumed, namely, that Alexandria and Syene were exactly 5000 stadia distant from each other, and that they were precisely under the same meridian. Both these positions are denied by Mr Bruce, who on this subject has made many observations which our limits will not allow us to notice. He states that there is at Asum an obelisk erected by Ptolemy Euergetes, the patron of Eratosthenes, without hieroglyphics, directly facing the south, with its top first cut into a narrow neck, then spread out like a fan into a semicircular form, with pavements curiously levelled to receive the shade, and make the separation of the true shadow from the penumbra as distinct as possible. This is supposed by Mr Bruce to have been constructed with a design to vary the experiment of Eratosthenes with a larger radius; and the inquiry concerning the dimensions of the earth, in our author's opinion, was the occasion of many obelisks being erected in this kingdom; a demonstration of which is, that the figure of the top is varied; being sometimes very sharp, and sometimes a portion of a circle, in order to get rid of the great impediment arising from the penumbra, which makes it difficult to determine the length of the shadow with precision. It is now called *Assouan.*

SYLAH, a large fortified town of Hindustan, in the province of Gujerat. It belongs to a Hindu chief, who is tributary to the Guicowar.

SYLLA, Lucius Cornelius, a Roman memorable for his vices and cruelties, and for relinquishing the dictatorship two years after he had compelled the people to elect him. See Roman History.

SYLLABLE, in *Grammar*, one or more letters pronounced by a single impulse of the voice, forming a complete sound, and constituting a word or a part of a word. No single letter except a vowel can form a syllable. The longest syllable in the English language is the word *strength*. The most natural way of dividing words into syllables is, to separate all the simple sounds of which any word consists, so as not to divide those letters which are joined close together according to the most accurate pronunciation.

SYLLABUS, in matters of literature, denotes a table of contents, or an index of the chief heads of a book or discourse.

SYLLOGISM, in *Logic*, an argument or term of reasoning, consisting of three propositions, of which the first two are called *premises*, the last, the *conclusion*.

SYMBOL, a sign or representation of something moral, by the figures or properties of natural things. Hence symbols are of various kinds; as hieroglyphics, types, enigmas, parables, fables, &c.

SYMMACHUS, Quintus Aurelius, a Latin writer of high reputation during his own time, was born at Rome, being the son of Lucius Avianus Symmachus, who became prefect of the city in the year 364. The son was carefully initiated in the learning of the age, and soon distinguished himself by his talents and eloquence. He became proconsul of Africa in 370, and prefect of the city in 384. He likewise appears to have filled the office of *pontifex*. While he held that of prefect, he addressed to Valentinian II., Theodosius, and Arcadius, an elaborate epistle, urging the restoration of the pagan rites and observances. This application produced no effect, but his zeal for the ancient superstition was still unabated; and in 388 or 389, when congratulating Theodosius, he again, in the name of the senate, entreated him to restore the altar of Victory to the senate-house. But the emperor, who had a more personal reason for being dissatisfied with his conduct, on account of his favourable sentiments towards the usurper Maximus, sent him into exile at a great distance from Rome. His disgrace does not however appear to have been lasting; for he was nominated consul in the year 391. He survived Theodosius, and was employed by his sons Arcadius and Honorius.

Symmachus is chiefly known to posterity as the author of ten books of Epistles, which reflect some light on the history of that era. He seems to have chosen Pliny as his model; but he belongs to a very inferior age of Latinity, and has a due share of the quaintness and affectation by which it is generally characterized. His *relatio* in favour of paganism (lib. x. epist. lxi.) produced a refutation from Ambrose bishop of Milan, who on that subject addressed two epistles to Valentinian. He was likewise assailed by Prudentius, who composed a poem in two books "Contra Symmachum Præfectum Urbis." Of the literary merit of his adversary, the Christian poet has expressed the highest admiration:

> O linguam miro verborum fonte fluentem,
> Romani decus eloquii, cui cedat et ipse
> Tullius, has fundit dives facundia gemmas.
> Os dignum æterno tinctum quod fulgeat auro,
> Si mallet laudare Deum, cui sordida monstra
> Prætulit, et liquidam temeravit crimine vocem.

The *Epistolæ* of Symmachus are said to have been printed before the close of the fifteenth century, and other very early editions are mentioned. Only 317 epistles appear in the edition printed by J. Schott, Argent. 1510, 4to. The subsequent impressions include 965, divided into ten books. The next edition was printed by Froben, Basil. 1549, 8vo. An edition, illustrated with notes, was afterwards prepared by Juretus, Paris. 1580, 1604, 4to. To the annotations of this editor, Lectius added his own, Genev. 1587, 1599, 8vo. The text of Lectius is preferable to that of Juretus. Another edition, accompanied with notes, was published by Scioppius, Mogunt. 1608, 4to. These notes he was accused of having pilfered from the papers of Giphanius.[1] The next editions of Symmachus were those of Pareus, Neapoli Nemetum, 1617, 1628, Francof. 1642, 8vo. He added a "Lexicon Symmachianum," and "Electa Symmachiana." We have only to mention another edition, Lugd. Bat. 1653, 12mo. Of the orations of Symmachus some fragments were discovered in the Ambrosian Library at Milan by the indefatigable Angelo Mai, and by him have been communicated to the public, under the title of "Q. Aurelii Summachi, V. C. octo Orationum ineditarum partes. Invenit notisque declaravit Angelus Maius, Bibliothecæ Ambrosianæ a Linguis Orientalibus. Accedunt additamenta quædam." Mediolani, 1815, 8vo. (x.)

SYMPATHY, an agreement of affections and inclinations, or a conformity of natural qualities, humours, and temperaments. Sympathy also denotes the quality of being affected by the affection of another, and may subsist either between different persons or bodies, or between different parts of the same body. It is either similar or dissimilar; similar when the affection or action in the sympathiser is similar to the affection or action in the sympathant, and dissimilar when these are different. Sympathy, too, is often an imitative faculty, sometimes involuntarily, frequently without consciousness. Thus we yawn when we see others yawn, and are made to laugh by the laughing of another.

SYMPHEROPOLE, the capital city of the Russian province of Krimea. It stands on the southern part of the peninsula, about twenty miles from the sea, in a fine valley at the base of the Tauridan Mountains, on the small river Salghir. It was the residence of the khans or chiefs of the peninsula till it was seized by the Russians. It now consists of two parts; the European part, built since 1783 by the Europeans, and the Tartar or Asiatic part, which, till very lately, consisted of structures in the peculiar fashion of the natives. The new town displays wide streets; and, besides the crown buildings, the houses of the governor and vice-governor, the police, the hospital, and the barracks, there is a considerable number of handsome edifices. The cathedral is yet unfinished, though a large sum has been expended on it. It is on the spot where Suwarof gained a great victory over the Turks. The city is now said to contain about 10,000 inhabitants, its prosperity having increased within the last twenty years.

SYMPHONY (Ital. *Sinfonia*). Anciently this word had various musical meanings. It now usually signifies a piece of instrumental music for an orchestra, consisting of several movements, and generally performed in a concert-room. The overture differs from the symphony chiefly in the smaller number of its movements, seldom containing more than a short, slow, introductory movement, and an allegro, and being used at the beginning of an opera or a ballet. The word symphony is also used to signify an instrumental passage which usually introduces a piece of vocal music, or is brought in at its close, or occurs during some pause of the voice. Haydn, Mozart, and Beethoven have produced the finest models of the orchestral symphony in point of originality, beauty, ingenious construction, and skilful instrumentation. For clearness of design and breadth of effect, Haydn's symphonies still remain unrivalled.

---

[1] Fabricii Bibliotheca Latina, tom. iii. p. 208. edit. Ernesti.

SYMPLOCE, συμπλοκή, in *Rhetoric*, a figure, where the same word is repeated several times in the beginning and end of a sentence, including the *Anaphora* and *Epitrophe*. Thus, "Quis legem tulit? Rullus. Quis majorem populi partem suffragiis privavit? Rullus. Quis comitiis præfuit? Idem Rullus."

SYMPOSIARCH, in *Antiquity*, the director or manager of an entertainment. This office was sometimes performed by the person at whose charge the entertainment was provided, sometimes by another named by him; and at other times, especially in entertainments provided at the common expense, he was elected by lot, or by the suffrages of the guests.

SYNÆRESIS, CONTRACTION, in *Grammar*, a figure by which two syllables are united in one; as *vemens* for *vehemens*.

SYNAGOGUE, among the Jews, is a place where that people met to worship God. Authors are not agreed about the time when the Jews first began to have synagogues. Some suppose them as old as the ceremonial law, and others fix their beginning to the times after the Babylonish captivity. They erected synagogues not only in towns and cities, but also in the country, especially near rivers, that they might have water for their purifications and ceremonial washings. No synagogue was built in any town unless there were ten persons of leisure in it; but there might be many in one town, or in one quarter of a town, provided it was very populous. Jerusalem is said to have contained 480. The chief things belonging to a synagogue were, 1. the ark or chest, made after the model of the ark of the covenant, containing the Pentateuch; 2. the pulpit and desk in the middle of the synagogue, in which he that was to read or expound the law stood; 3. the seats or pews for the people; 4. the lamps to give light at evening service, and the feast of dedication; 5. rooms or apartments for the utensils and alms-chest. The synagogue was governed by a council or assembly, over whom was a president, called the Ruler of the Synagogue. These are sometimes called Chiefs of the Jews, the Rulers, the Priests or Elders, the Governors, the Overseers, the Fathers of the Synagogue. Their business was to punish the disobedient, by censures, by excommunication, or by penalties, such as fines and scourging; to take care of the alms, which are frequently called by the name of righteousness. The chief ruler, or one of the rulers, gave permission to read and expound the law, and appointed who should do it. In every synagogue there were several ministers, who had different offices assigned to them. Service was performed three times a day, namely, in the morning, in the afternoon, and at night. At the time of morning sacrifice, evening sacrifice, and after the evening sacrifice on Monday, Thursday, and Saturday, there was a more forcible obligation upon the people to attend than upon the other days.

SYNALOEPHA, in *Grammar*, a contraction of syllables, performed principally by suppressing some vowel or diphthong at the end of a word, on account of another vowel or diphthong at the beginning of the next. As, *ill' ego*, for *ille ego*, &c.

> Conticuer' omnes intentiqu' ora tenebant. VIRGIL.

It is called by the Latins *collisio*.

SYNCELLUS, or SINCELLUS, an ancient officer in the family of the patriarchs and other prelates of the eastern church. The word, in the corrupt Greek, σύγκελλος, signifies a person who lies in the chamber with another; a *chamber-fellow*, or *chum*. The syncellus was an ecclesiastic, who lived with the patriarch of Constantinople, to be a witness of his conduct; whence it is that the syncellus was also called the *patriarch's eye*, because his business was to observe and watch. The other prelates had also their syncelli, who were clerks living in the house with them, and even lying in the same chamber, to be witnesses of the purity of their manners. The office afterwards degenerated into a mere dignity; and there were made syncelli of churches. At last, it became a title of honour, and was bestowed by the emperor on the prelates themselves; whom they called *pontifical syncelli*, and *syncelli Augustales*.

SYNCHRONISM denotes the happening of several things at the same time.

SYNCOPATION, in *Music*. See SLUR.

SYNCOPE, FAINTING; a deep and sudden swooning, during which the vital functions are suspended.

SYNCOPE, in *Grammar*, an elision or retrenchment of a letter or syllable out of the middle of a word, as *caldus* for *calidus*.

SYNDIC, an officer, in divers countries, intrusted with the affairs of a city or other community, who calls meetings, makes representations and solicitations to the ministry, magistracy, &c. according to the exigency of the case.

SYNECDOCHE, in *Rhetoric*, a kind of trope frequent among orators and poets.

SYNECPHONESIS, in *Grammar*, a coalition, by which two syllables are pronounced as one; being much the same as SYNALOEPHA and SYNÆRESIS.

SYNOD, in *Astronomy*, a conjunction or concourse of two or more stars or planets, in the same optical place of the heavens.

SYNOD signifies also a meeting or assembly of ecclesiastical persons to consult on matters of religion.

SYNODALS, or SYNODIES, were pecuniary rents (commonly of two shillings), paid to the bishop, or archdeacon, at the time of their Easter visitation, by every parish priest. They were thus called, because usually paid in synods. For the same reason, they are sometimes also denominated *synodalica*; but more usually, *procurations*.

SYNODICAL, something belonging to a synod. Thus, synodical epistles are circular letters written by the synods to the absent prelates and churches; or even those general ones directed to all the faithful, to inform them of what had passed in the synod.

SYNOECIA, in Grecian antiquity, a feast celebrated at Athens in memory of Theseus's having united all the petty communities of Attica into one single commonwealth, the seat of which was at Athens, where all the assemblies were to be held. This feast was dedicated to Minerva; and, according to the scholiast on Thucydides, it was held in the month *Metagitnion*.

SYNONYMOUS is applied to a word or term that has the same import or signification with another. Several works have been composed for the express purpose of explaining synonymous words. In 1777 a work was published on the Latin synonymes at Paris by M. Gardin Dumesnil. The Abbé Girard published one on the synonymous terms of the French language many years ago. Another was published on the same subject in the year 1785 by the Abbé Roubaud. An account of the English synonymes was published by an anonymous author in 1766. This work is a close imitation, and in some parts a literal translation, of Girard's "Synonymes François." A rambling work, abounding with errors, was published by Mrs Piozzi, under the title of "British Synonymy." Lond. 1794, 2 vols. 8vo. A much better book, more recently published, by Mr Crabb, is entitled "English Synonymes explained." Lond. 1816, 8vo. Lond. 1826, 4to.

SYNTAX, in *Grammar*, the proper construction or due disposition of the words of a language into sentences and phrases.

SYNTHESIS, in *Logic*, denotes a branch of method, opposite to analysis. In the synthesis or synthetic method, we pursue the truth by reasons drawn from principles before established or assumed, and propositions formerly proved;

thus proceeding by a regular chain, till we come to the conclusion. Such is the method in Euclid's Elements, and most demonstrations of the ancient mathematicians, which proceed from definitions and axioms, to prove propositions, &c. and from those propositions proved to prove others. This method we also call *composition*, in opposition to *analysis* or *resolution*.

SYRA, an island in the Grecian archipelago, classed among the Cyclades, anciently called Syros. The south-west point of the island is north-east from Serpho-Poulo about five leagues, and the summit of its high land, which is towards the east, is in longitude 24° 55′ 13″ east, and latitude 37° 28′ 56″ north. It is three leagues long from north to south, and about one league and a half in breadth. It is mountainous and destitute of wood; but being well watered and well cultivated, produces barley, wine, figs, cotton, olives, and a small portion of wheat. There is a good harbour on the eastern side, very secure for vessels of an easy draught, and where two or three frigates might find shelter. The land has a very picturesque appearance from this harbour, near to which is the town, reaching half way down the side of a conical hill. The whole inhabitants are calculated to be about 2000, mostly adhering to the Roman Catholic church.

t what me built.

SYRACUSE, a celebrated city of Sicily, and once the capital of the island. According to Thucydides and Strabo, it was built by Archias, one of the Heraclidæ, who came from Corinth into Sicily in the second year of the 11th Olympiad, and derived its name from a neighbouring marsh named *Syraco*. What form of government first prevailed in the city, is not known. Many have supposed it originally to have been governed by kings: but if this was the case, the monarchical government continued only for a very short time; since Aristotle, Diodorus Siculus, and Justin, mention it as being very early subject to a democracy. The history is obscure and unimportant till the time of Gelon, when Syracuse first began to make a conspicuous figure.

elon seizs on the overeigny.

Gelon was born in the city of Gela in Sicily, of the family of Telines, who had been created priest of the infernal gods. He signalized himself in a war carried on against the Syracusans, by Hippocrates, tyrant of Gela, whom he defeated in a pitched battle. Having thus become very powerful among his countrymen, he soon found means to seize on the sovereignty for himself. In a short time, having put himself at the head of some Syracusan exiles, he marched towards that place, where he was received with loud acclamations, and obtained possession of the city.

In order to people the capital of his new dominions, Gelon first demolished the neighbouring city of Camarina, and transplanted the inhabitants to Syracuse. Soon afterwards, entering into a war with the Megareans, he defeated them, took and razed their cities, and in like manner transplanted the people. Syracuse thus became powerful, and full of inhabitants; and the friendship of Gelon was courted both by Athens and Lacedæmon at the time of the Persian invasion. In the mean time the Carthaginians had entered into a treaty with the Persians; by which it was agreed, that the former should attack those of the Greek name in Sicily and Italy, in order to divert them from assisting each other. Sicily was accordingly invaded by the Carthaginians with a vast army; but they were utterly overthrown by Gelon, as is related under the article Carthage. After this victory, the people out of gratitude obliged him to assume the title of king, which till that time he had refused. A decree also passed by which the crown was settled on his two brothers Hiero and Thrasybulus after his death. The new king, instead of keeping his subjects in greater awe, studied to make them happy, and was the first man who became more virtuous by being raised to a throne. He was particularly famous for his honesty, truth, and sincerity; is said never to have wronged the meanest of his subjects, and never to have made a promise which he did not perform.

Defeats the arthaginians, and akes the itle of ing.

His excellent reign.

Gelon dies, and is succeeded by Hiero. B. C. 471.

Gelon died in the year 471 B. C. after having reigned three or four years; and was succeeded by his brother Hiero, whose character is differently drawn by different historians. He is highly celebrated in the odes of Pindar; and it is certain that his court was the resort of men of wit and learning, to whom he behaved in the most courteous manner and with the greatest liberality.

Thrasybulus, a tyrant.

In 459 B. C. Hiero was succeeded by Thrasybulus; who proving a tyrant, was in ten months dethroned, and a popular government restored, which continued for the space of fifty-five years.

The Siculi subdued.

About this time the Syracusans entered into a war with the Siculi, which terminated in the total subjection of the latter; after which Syracuse became so powerful, that it in a manner gave law to the whole island. The Greek cities indeed enjoyed a perfect liberty, but they all acknowledged Syracuse as their metropolis. By degrees, however, the latter began to assume such an authority over them as was totally inconsistent with liberty; and this occasioned many wars, which involved them in much distress and danger. They began with the Leontines, whose territory they laid waste, and reduced their city to great straits. Leontini was an Athenian colony; and this furnished the Athenians, who had already meditated the conquest of Sicily, with a pretence to attack the Syracusans with their whole force. Under colour of assisting their countrymen, therefore, they sent a fleet of 250 sail to Sicily; but the Leontines, sensible that their pretended allies aimed at nothing less than the conquest of the whole island, concluded a peace with Syracuse; and the disappointed Athenians vented their rage on those who had advised and conducted the expedition.

Syracuse invaded by the Athenians without success.

New invasion by the Carthaginians.

During the continuance of the popular government, the Syracusans took part in the long war between Athens and Sparta. This war was scarcely ended, when a new and formidable invasion by the Carthaginians took place; but the event of that expedition was as unfortunate to the Carthaginians as the former had been. In the mean time, a considerable revolution had happened in Syracuse. The city of Agrigentum had been taken by the Carthaginians; and of the few inhabitants who escaped, some fled to Syracuse, where they accused the Syracusan commanders of having betrayed the city into the hands of the enemy. Dionysius, a man of great valour and address, but who had become very obnoxious to the populace, took this opportunity of attempting to retrieve his credit. He therefore supported the accusations brought against his countrymen by the Agrigentines, and even impeached the magistrates as having a secret intelligence with the enemy, and attempting to introduce an oligarchy. As his speech was entirely levelled against the more wealthy, it was very agreeable to the poorer citizens: the commanders were instantly degraded; and others, among whom was Dionysius, were appointed. Having once gained this point, he began to consider how he might effect the dismission of his colleagues. For this purpose, he never joined in any council of war with the other commanders, nor imparted to them his resolutions, giving out that he could not trust them, and that they had more regard for their own interest than the welfare of their country. But while he was proceeding in this manner, the more prudent part of the citizens, perceiving what he aimed at, complained of him to the senate and magistrates, and fined him as a disturber of the public peace. According to the laws, the fine was to be paid before he could speak in public, and the circumstances of Dionysius did not allow him to discharge it. In this dilemma he was assisted by Philistus the historian, a man of great wealth, who not only paid this fine for him, but encouraged him to speak his

Rise of Dionysius.

mind freely, as it became a zealous citizen to do, promising to pay all the fines which should be imposed upon him.

Being extricated out of this difficulty, Dionysius next proceeded, with all the eloquence of which he was master, to inveigh against those who by means of their power or interest were able to oppose his designs, and by degrees brought them into discredit. His next scheme was to get those exiles recalled whom the nobility had banished at different times; as thinking that they would support him with all their power, as well out of gratitude, as out of hatred to the opposite party. Having likewise gained this point, he next found means to ingratiate himself with the soldiery to such a degree that, under pretence of taking proper measures for resisting the Carthaginians, he was chosen commander in chief, with absolute and unlimited power. This was no sooner done than, pretending his life was in danger, he selected 1000 men for his guard, whom he attached to his interest by great promises. As no person durst now oppose him, he possessed himself of the capital, where all the arms and provisions were kept; after which he publicly took the title of king of Syracuse in the year 404 B. C. The Syracusans did not tamely submit to their new master; but Dionysius managed matters so well, that their frequent revolts answered no other purpose than more certainly to entail slavery on themselves; and he was allowed to possess the throne without much opposition till his death, which happened in the year 366 B. C.

who becomes king of Syracuse. B. C. 404.

Dionysius II. B. C. 366.

On the death of Dionysius, he was succeeded by his son, likewise called Dionysius. He was naturally of a mild and peaceable temper, averse to cruelty, and inclined to learning; but his father, to whom all merit, even in his own children, gave umbrage, stifled as far as possible his good qualities by a mean and obscure education. He no sooner ascended the throne, than Dion, brother to Aristomache, wife of the elder Dionysius, undertook to correct the faults of his education, and to inspire him with thoughts suitable to the high station in which he was placed. For this purpose he sent for the philosopher Plato, under whose care he immediately placed the young king. This instantly produced a reformation on Dionysius; but the courtiers, dreading the effects of the philosopher's instructions, prevailed on him to banish Dion, and to keep Plato himself in a kind of imprisonment in the citadel. At last, however, he set him at liberty; and Plato then returned to his own country.

Put under the care of Plato by his uncle Dion, whom he banishes.

Dion, in the mean time, visited several of the Grecian cities, and at last took up his residence in Athens; but the honours which were everywhere paid him raised such jealousies in the breast of the tyrant, that he stopped his revenue, and caused it to be paid into his own treasury. In a short time Dionysius again sent for Plato; but, finding it impossible to dissolve the friendship between him and Dion, disgraced, and placed him in a very dangerous situation, in the midst of assassins who hated him. Not daring, however, to offer him any violence, he allowed him soon after to depart; revenging himself on Dion, whose estate he sold, and gave his wife Arete in marriage to Timocrates, one of his flatterers.

Dion raises troops for dethroning the tyrant.

Dion now resolved to revenge himself on the tyrant for the many injuries which he had sustained, and at once to deliver his country from the oppression under which it groaned. He began with raising foreign troops privately, by proper agents, for the better execution of his design. Many Syracusans of distinction entered into his scheme, and gave him intelligence of what passed in the city; but of the exiles, of whom there were upwards of 1000 dispersed up and down Greece, only twenty-five joined him; so much were they awed by the dread of the tyrant. The troops were assembled at the island of Zacynthus, in number only about 800; but who had all been tried on many occasions, were well disciplined, and capable of animating by their example the forces which Dion hoped to find in Sicily. When they were about to sail, Dion acquainted them with his design, the boldness of which at first occasioned among them no small consternation; but he soon removed their fears, by telling them that he did not lead them as soldiers, but as officers, to put them at the head of the Syracusans and all the people of Sicily, who were ready to receive them with open arms. Having then embarked in two small trading vessels, they arrived in twelve days at Cape Pachynum, near Syracuse. They at length reached the port of Minoa, not far from Agrigentum, and here they received intelligence that Dionysius had set sail for Italy, attended by a fleet of eighty galleys. Dion now resolved to take advantage of the tyrant's absence, and immediately proceeded to Syracuse. On his march he prevailed on the inhabitants of Agrigentum, Gela, Camarina, and other cities, to join him. As soon as he entered the territories of Syracuse, multitudes flocked to him; and as nobody appeared to oppose him, he boldly entered the city, where he quickly found himself at the head of 50,000 men. As soon as he had landed in Sicily, Timocrates, to whom his wife Arete had been given by Dionysius, and to whom the care of the city had been left, despatched a courier to let the tyrant know the danger to which he was exposed. Dionysius was, however, accidentally prevented from receiving a timely account of Dion's arrival; so that when he entered the citadel by sea, seven days after Dion's arrival, he found his affairs in a desperate situation. Upon this he had recourse to artifice; and having amused the Syracusans by a feigned negociation, until he observed that they kept a negligent guard, he attacked them all at once with such fury, that he had almost taken the city. But Dion encouraged the soldiers by his example so much, that he at last obtained a complete victory; for which they presented him with a crown of gold. It was not long, however, before the ungrateful Syracusans began to think of conferring quite different rewards on their benefactor. Dionysius had the address to render him suspected by the multitude; at the same time that Heraclides, an excellent officer, but a secret enemy to Dion, did all that lay in his power to sink his credit. Dionysius was soon obliged to fly into Italy, but left Heraclides to oppose Dion.

Enters Syracuse without oppositio

Dionysiu arrives, is totally defeated

Ingratit of the S racusans Dion.

Dion at length obtained possession of the city, and Heraclides having submitted to him, was received into favour; but as his seditious and turbulent behaviour still continued, Dion at last gave orders to put him to death. This action, however necessary, so affected the mind of Dion, that he became melancholy; and ever after imagined himself haunted by a frightful spectre, resembling a woman of gigantic stature, with the haggard looks and air of a fury. In a short time after he lost his life, through the treachery of Calippus, or Gylippus, who pretended to be his intimate friend, and who immediately after caused his wife and sister to be carried to prison. Calippus having removed Dion, soon made himself master of Syracuse, where he committed all manner of cruelties; but he was driven out, and forced to fly to Rhegium, where he was murdered by the same dagger which had killed Dion. In 350 B. C. Dionysius again made himself master of Syracuse; and being exasperated by his past misfortunes, became more tyrannical than ever. The Syracusans first had recourse to Icetas, tyrant of Leontini; but as the Carthaginians took this opportunity to invade them with a powerful fleet and army, they were obliged to apply to the Corinthians. By them Timoleon, a celebrated commander, was sent to the assistance of the Syracusans, whom he found in a very distressed situation; Icetas being master of the city, the Carthaginians of the harbour, and Dionysius of the citadel. As all parties were equally the enemies of Dionysius, he found it impossible to resist, and therefore surrendered himself to Timoleon, by whom he was sent to Corinth; where at last he was reduced to the necessity of teaching a school for his support.

Dion be comes n lancholy and is n dered.

Cowardice of the Carthaginians.

After the expulsion of the tyrant, Timoleon withdrew to Catana, leaving only 400 Corinthians, under the command of an experienced officer named Leon, to guard the citadel. These were immediately besieged by Icetas and the Carthaginians, but Timoleon found means to relieve them in spite of all opposition; and having dispersed emissaries through the army of Mago the Carthaginian general, exhorting the mercenary Greeks to forsake him, he was so much intimidated, that in spite of all the remonstrances which Icetas could make, he set sail for Africa, leaving his colleague to carry on the war in the best manner he could.

Citadel of Syracuse and other forts demolished by Timoleon.

He repeoples the city.

Dies, and is honoured as a god.

The day after the departure of Mago, Timoleon assaulted the city so fiercely, that the troops of Icetas were driven from the walls, and the Corinthians became masters of the place. Timoleon, by sound of trumpet, invited the inhabitants to come and assist in demolishing the citadel and other castles, which he called the *nests of tyrants;* after which he caused edifices for the administration of justice to be erected in the place where the citadel had stood. He found the city in a most miserable condition; for many having perished in the wars and seditions, and others having fled to avoid the oppression of tyrants, Syracuse, once so wealthy and populous, was now become almost a desert; insomuch that the horses were fed on the grass which grew in the market-place. Timoleon supplied the city with inhabitants from Corinth and other cities of Greece, at the same time that great multitudes from Italy and the other parts of Sicily resorted thither. Timoleon distributed the lands among them; but sold the houses, and with the money arising from the sale established a fund for the support of the poor. Having thus restored Syracuse, he next delivered all the Greek cities of Sicily from the tyrants who had taken possession of them, all of whom he put to death. After this he resigned his authority, and led a retired life, venerated in the highest degree by the Syracusans, and by all the cities in Sicily. After his death he was honoured as a god; the expense of his funeral was defrayed by the public; sports, with horse-races and gymnastic exercises, were held annually on the day of his death; and it was decreed, that whenever the Syracusans were at war with the barbarians, they should send to Corinth for a general.

Syracuse again falls under the power of tyrants.

Pyrrhus king of Epirus invited into Sicily.

Syracuse harassed by the Mamertines.

For twenty years the Syracusans enjoyed the fruits of Timoleon's victories; but new disturbances arising, in a short time another tyrant started up, who exceeded all that had gone before him in cruelty and other vices. This was the celebrated Agathocles, of whose exploits against the Carthaginians a full account is given under the article CARTHAGE. He was poisoned by one Mœnon in the year 289 B. C., after having reigned twenty-eight and lived ninety-five years. A succession of tyrants followed, till at last the city, being held by two rivals, Tœnion and Sosistratus, who made war within the very walls, Pyrrhus king of Epirus was invited into Sicily, in order to put an end to these distractions. He willingly complied with the invitation, and was everywhere received with loud acclamations, as the deliverer, not only of Syracuse, but of all Sicily. As he had a fine army of 30,000 foot and 5000 horse, with a fleet of 200 sail, he drove the Carthaginians from place to place, till he left them only the two strong posts of Eryx and Lilybæum. The former of these he took by assault, and was himself the first man who mounted the walls, after having killed a great number of Africans with his own hand. The Mamertines, likewise, who had conquered a considerable part of the island, were everywhere defeated and driven out, till at last they were shut up in the city of Messana. The Carthaginians, alarmed at the rapidity of his conquests, sent ambassadors with proposals of peace upon very advantageous terms; but Pyrrhus, elated by the expectation of reducing the whole island, refused to hearken to any terms unless they would instantly abandon it. So sanguine were his anticipations, that he caused his son to assume the title of king of Sicily; but in the mean time, having displeased the Sicilians by his arbitrary behaviour, they deserted from him in such numbers that he was glad to set out for Italy, for which retreat the embassies he received from the Samnites, Tarentines, and other Italians, furnished him with an honourable pretext. He embarked in the ships which he had brought with him from Italy, but was met at sea by the Carthaginians, who sunk seventy of his vessels, and dispersed or took the rest, so that he saved himself in Italy with only twelve vessels, the poor remains of a fleet of 200 sail. No sooner were the Mamertines apprised of his departure, than they despatched a body of 18,000 men to harass him after his landing. These having passed the straits before him, posted themselves on the road which Pyrrhus must take in marching by land to Tarentum, and concealing themselves among woods and rocks, attacked him unexpectedly, and with great resolution. But Pyrrhus behaved on this occasion with his usual bravery. The attack being made on his rear, he hastened thither, and made a dreadful slaughter of the enemy, till a wound in the head obliged him to retire.

Hiero chosen general of the Syracusan forces.

Is elected king of Syracuse. B. C. 265.

After the departure of Pyrrhus, Hiero the son of Hierocles, a descendant of Gelon, the first king of Syracuse, was chosen general of the forces, along with another named Artemidorus. The two generals had nothing more at heart than to put an end to the confusion and disorder which reigned in the city; and with this view they entered it at the head of their forces. On this occasion Hiero discovered extraordinary talents for government. By mere dint of insinuation and address, without shedding blood or hurting a single citizen, he calmed the minds of the people, reconciled the factions, and so gained the affections of all, that he was invested with the whole civil as well as military power in the state. He soon afterwards married the daughter of one of the first citizens; and having distinguished himself by his exploits against the Mamertines, was unanimously elected king of Syracuse in the year 265 B. C.

Some time after Hiero's accession to the throne, he again defeated the Mamertines, and reduced them to such straits that they were obliged to call in the Romans to their assistance. The consequences of this have been fully related under the articles ROME and CARTHAGE. Hiero, who had allied himself with the Carthaginians, being himself defeated by the Romans, and finding his allies unable to protect him against the power of that republic, concluded an alliance with them, and continued faithful to them even in the time of the second Punic war, when they were in the greatest distress. In his reign flourished the celebrated mathematician Archimedes, whose genius he employed in fortifying the city of Syracuse, by innumerable machines, in such a manner as rendered it absolutely impregnable to every method of attack known at that time.

Hieronymus.

Syracuse invested.

Hiero died about 211 B. C. and was succeeded by his grandson Hieronymus; but he imprudently forsook the counsels of his grandfather, and entered into an alliance with the Carthaginians. He was soon afterwards murdered, in consequence of his tyranny and cruelty; and the greatest disorders took place in the city, which Hannibal, though then in Italy, found means to foment, in hopes of keeping the Syracusans in his interest. This indeed he effected; but as his own affairs in Italy began to decline, he could not prevent Marcellus from landing in Sicily with a formidable army, which the Sicilians had no means of resisting. Syracuse was soon invested; but the machines invented by Archimedes baffled all attempts to take it by assault. The immense preparations which the consul had made for taking the city by storm, could not have failed to accomplish his purpose, had the place been otherwise defended than by the genius of Archimedes. The Roman fleet consisted of sixty quinqueremes, besides a far greater number of other ships. The decks were covered with soldiers armed with darts, slings, and bows, to drive the besieged from the ramparts, which on one side were washed by the sea, and to facilitate the approach to the walls. But a machine of Marcellus's own invention, called a *sambuca*, was that on which he placed his chief reliance. The consul's design was to bring his sambuca to the foot of the walls of Acradina; but while it was at a considerable distance (and it advanced very slowly, being moved only by two ranks of rowers), Archimedes discharged from one of his engines a vast stone, weighing, according to Plutarch's account, 1250 pounds, then a second, and immediately after a third, all which, falling upon the sambuca with a dreadful noise, broke its supports, and gave the galleys upon which it stood such a violent shock that they parted, and the machine which Marcellus had raised upon them with immense labour and expense was battered to pieces. At the same time, several other machines, which were not visible without the walls, and consequently did not lessen the confidence of the Romans in the assault, played incessantly upon their ships, and overwhelmed them with showers of stones, rafters, and beams pointed with iron, insomuch that Marcellus found it necessary to retire with all possible haste, and sent orders to his land forces to do the same; for the attack on the land side was attended with no better success, the ranks being broken and thrown into the utmost confusion by the stones and darts, which flew with such noise, force, and rapidity, that they struck the Romans with terror, and dashed all to pieces before them.

Incredible effects of the machines of Archimedes.

Marcellus, surprised, though not discouraged, at this artificial storm, which he did not expect, held a council of war, in which it was resolved, the next day before sunrise, to advance close to the wall, and remain there. They were in hopes by this means to secure themselves against the terrible storm of stones and darts which fell on the ships when at a distance; but Archimedes had prepared engines which were adapted to all contingencies. When the Romans therefore had brought their ships close under the wall, and thought themselves well covered, they were unexpectedly overwhelmed with a new shower of darts and stones, which fell perpendicularly on their heads, and obliged them to retire with great precipitation. But they had no sooner removed to some distance, than a new shower of darts overtook them, which made a dreadful havock of the men, while stones of an immense weight, discharged from other machines, either disabled or broke in pieces most of their galleys. This loss they sustained without being able to revenge it on the enemy; for Archimedes had placed most of his engines behind the walls, and not only out of the reach, but even out of the sight, of the enemy; so that the Romans were repulsed with a dreadful slaughter, without seeing the hand that occasioned it. What most harassed them in the attack by sea, was a sort of crow with iron claws, fastened to a long chain, which was let down by a lever. The weight of the iron made it fall with great violence, and drove it into the planks of the galleys. Then the besieged, by a great weight of lead at the other end of the lever, weighed it down, and consequently raised up the iron of the crow in proportion, and with it the prow of the galley to which it was fastened, sinking the poop at the same time into the water. After this the crow letting go its hold all of a sudden, the prow of the galley fell with such force into the sea, that the whole vessel was filled with water, and sunk. At other times, the machines, dragging ships to the shore by hooks, dashed them to pieces against the points of the rocks which projected under the walls. Other vessels were quite lifted up into the air, there whirled about with incredible rapidity, and then let fall into the sea, and sunk, with all that they contained. How these stupendous works were effected, few, if any, have hitherto been able to comprehend.

The troops under the command of Appius suffered no less than the fleet in this second attack. In the whole space of ground which the army occupied when formed, the last files as well as the first were overwhelmed with showers of darts and flints, against which they could not possibly defend themselves. When they had with infinite trouble brought the mantlets and covered galleries, under which they were to work the rams, near the foot of the wall, Archimedes discharged such large beams and stones upon them as crushed them to pieces. If any brave Roman ventured to draw too near the wall, iron hooks were immediately let down from above, which, taking hold of his clothes or some part of his body, lifted him up in the air and dashed out his brains with the fall. Marcellus, though at a loss how to proceed, could not however forbear expressing himself with pleasantry. Shall we persist, said he to his workmen, in making war upon this Briareus, upon this giant with an hundred hands? But the soldiers, if they saw upon the walls only a small cord, or the least piece of wood, were so terrified, that they immediately turned their backs and fled, crying out that Archimedes was going to discharge some dreadfil machine upon them.

The siege turned in a blockad

The consuls, finding themselves thus defeated in every attempt, turned the siege into a blockade, reduced most of the other places in the island, and defeated the forces which were sent against them; and at last Marcellus made himself master of Syracuse itself. He took the opportunity of a festival, when the soldiers and citizens had drunk plentifully, to make a detachment scale the walls of Tyche, in that part of it which was nearest to Epipolæ, and which was ill guarded. He speedily possessed himself of Epipolæ; and the inhabitants of Neapolis, as well as Tyche, then sent deputies to offer their submission. Marcellus granted life and liberty to all of free condition, but gave up those quarters of the city to be plundered. The soldiers had orders to spare the lives of the citizens; but they were cruel in their avarice, slew many of them, and among the rest the incomparable Archimedes. He was very intent on a demonstration in geometry, and calmly drawing his lines, when a soldier entered the room, and applied a sword to his throat. "Hold!" said Archimedes, "one moment, and my demonstration will be finished." But the soldier, equally regardless of his prayer and his demonstration, instantly put him to death. Of the manner of his death there are different accounts, but all agree that Marcellus regretted it extremely, and showed a singular favour to his relations for his sake.

Account the takin of Syracuse.

The city plundere and Arch medes ki ed.

Syracuse destroye by the S racens.

The city of Syracuse continued subject to the western empire till its declension, when the island of Sicily being ravaged by different barbarians, the capital also underwent various revolutions, till at last, in the ninth century, it was so destroyed by the Saracens that very few traces of its ancient grandeur are now to be seen. The ancient city of Syracuse was of a triangular form, and consisted of five parts or divisions. The circuit, according to Strabo, amounted to 180 stadia, or twenty-two English miles and four furlongs. This account Mr Swinburne once suspected of exaggeration; but after spending two days in tracing the ruins, and making reasonable allowances for the encroachments of the sea, he was convinced of the exactness of Strabo's measurement.

The modern city is the capital of an intendancy of its own name. It is situated on a noble harbour, with an excellent bottom, and a plentiful supply of fresh water; but though well adapted for a naval station, or for an extended commercial port, it is only visited by a few polaccas or other small coasting vessels. Lord Nelson, when in pursuit of the French expedition in 1798, was here enabled to water and provide his fleet with fresh meat in five days. The city is now fortified, and has a strong citadel. The streets are confined and narrow; the public buildings, though numerous, have little to recommend them. There is a museum and a public library, as well as some private cabinets. The country around, being abundantly irrigated, is highly fertile, producing wheat, oil, hemp, tobacco, fruits, and several kinds of delicious wines. The antiquities of this, formerly one of the most populous cities of Europe, are very numerous, and call to remembrance some of the most striking events of the history of the ancient world. The lighthouse is in long. 15. 16. 50. E. and lat. 37. 2. 58. N.

SYRIA.

SYRIA, a beautiful and extensive country of Asia, extending along the shore of the Mediterranean, is estimated to be 200 miles in length, and 100 in breadth. It is bounded on the west by the Mediterranean, and is divided from Asia Minor on the north by Mount Taurus and its branches; while on the east it has a vast and trackless desert, which stretches northwards from Arabia, and which separates it, though not by any distinct boundary, from the countries of Kurdistan and Irak Arabi. On the south it is bounded by Palestine. In ancient history the boundaries of Syria were never accurately defined. They have frequently extended so far south as to comprehend Palestine; while towards the east also, they were made to range indefinitely over the desert, or as far as the Euphrates. The stricter geography of modern times has assigned more definite and narrower limits to this country. The geographical features of Syria are chiefly formed by the great mountain chain of Lebanon or Libanus, and the minor chain of Anti-Libanus, which, branching off from Mount Taurus, on the frontier of Asia Minor, stretch southward along the whole length of the country in an irregular line, and interlock with the mountains of Judæa. The great chain of Libanus rises to its height at the distance generally of 60 or 70 miles from the shore of the Mediterranean; the intervening country consisting of luxuriant and fertile valleys, diversified with lower ranges of hills; the land rising, however, gradually, until it reaches its height. The ascent is extremely rugged; the road narrow, and often over craggy rocks; and the cold is intense, the mountains rising above the level of perpetual snow, which lies here to an unknown depth. Mr Buckingham found great difficulty in ascending the heights of Lebanon. The horses sunk deep in the snow, from which they could hardly be extricated. From the united effects of the constant glare of the snow, the lightness of the air, and the fatigue of the ascent, he experienced a giddiness as if he were intoxicated, and found it difficult to walk in a straight line. It occupied the party four hours from the cedars to the summit, and they were so fatigued that they were obliged to stretch themselves on the snow to recover breath. The prospect which the travellers enjoyed when they reached the top was grand and magnificent. On the west they had a view of the lower plain, and beyond, the boundless ocean; while to the east was seen the lower range of Anti-Libanus, still high, and covered with snow at its summit, which overlooks the Syrian desert. Burckhardt also mentions, that when he was near the summit he had an extensive view of the sea near Tripoli on the west; and to the east the Anti-Libanus range, with the intervening lakes. In this manner the country is everywhere diversified, in its interior, with mountains varying in their levels, situation, and appearance; and it may be divided into the higher and the lower regions, namely, those tracts which lie between the great mountain ranges of Libanus and Anti-Libanus; those, again, which lie eastward of this last interior range, extending southwards from Aleppo, and also from Damascus, and which are bounded to the eastward by other districts rocky and mountainous, and finally by the Syrian district; and, lastly, the lower tract, which descends from the mountains of Lebanon to the sea, which is still interspersed with lower ranges of hills.

The coast is generally low and flat; and where it is of any breadth between the Lebanon mountains and the Mediterranean, the country is blessed with extreme fertility. The valleys are productive, and yield abundantly the most valuable grains, as well as fruits, in great variety. The oranges of Tripoli, the figs of Beirout, and the pistachios of Aleppo, are held in particular esteem. The coast from Acre to Sidon, through which the road runs, presents a rich tract overgrown with thorns and thistles. The shore is abrupt, and the water deep; the villages thinly scattered, and the population apparently small, though this fine plain is capable of the highest fertility. The immediate neighbourhood of Sidon is a fine district; the plain at the foot of the hills, which is not above two miles wide, being entirely appropriated to extensive and shady groves and gardens, with lanes between them. The hills are also fruitful, and of a lower level than those farther to the south and to the east of the plains of Tyre. From Tripoli to Beirout the whole coast appears to be formed of sand accumulated by the prevailing westerly winds, and hardened into rocks, where, in order to form an artificial shelter, recourse must have been had to excavation. The plains in the vicinity of most of the towns along the coast have a pleasing and picturesque aspect, being generally covered with olive groves, and fine gardens filled with fruit-trees. This lower country is also well watered, numerous streams flowing down from the mountains, and supplying the means of irrigation, and of fertilizing the ground.

In ascending the sloping sides of Lebanon, all the varieties of European climate are experienced; and it is remarkable how successfully the industry of the inhabitants has triumphed over the inequalities of the ground, and other natural difficulties. Burckhardt mentions, that at Bshirrai, which is on a very elevated situation on Mount Lebanon, not far from its summit, and where nature seems to afford nothing for the sustenance of the inhabitants, numerous villages flourish, and every inch of ground is cultivated.[1] The town is surrounded with fruit trees, mulberry plantations, vineyards, fields of dhourra and other grain, though there is scarcely a natural plain twenty feet square. But the inhabitants meet this difficulty by building terraces, and thus, with singular industry, securing a portion of level ground to prevent the earth from being swept down by the winter rains, and retaining at the same time the water requisite for the irrigation of their crops. Water is abundant, and streams from numerous springs descend on all parts of the mountain country, and refresh the ground. Volney concurs in the same description. "By dint of skill and labour," he observes, "they have compelled a rocky soil to become fertile. Sometimes, to avail themselves of the waters, they have made a channel for them by means of a thousand windings on the declivities, or have arrested them in the valleys by embankments. At other times they have propt up the earth that was ready to roll down, by terraces and walls;" so that the mountains present the appearance of a staircase, or of an amphitheatre, each tier of which is a row of vines or mulberry trees, of which Volney mentions that he had counted from 100 to 120 tiers from the bottom of the valley to the top of the hill. This elevated and craggy region also presents singular appearances, and is often the scene of fatal accidents. Here a rock pierced by a torrent forms a natural cascade; another assumes the appearance of a natural wall; ledges of stones washed down by the waters resemble some of the fine ruins which abound in the country. In other places, the waters, undermining the rocks, have formed caverns or subterranean channels. At other times, rocks loosened, or thrown off their equilibrium, have been known to fall on the adjacent dwellings, and to crush the inhabitants. Such dangers, however, which are common to Alpine countries, do not deter the inhabitants from their elevated residences; the comparative security which they enjoy from Turkish oppression being accounted a compensation for these evils.

---

[1] Burckhardt's Travels in Syria and the Holy Land, p. 20.

The higher Libanus presents a steep and barren ascent, on which the traveller toils for two hours till he reaches the summit. The lower Libanus is a more wooded country, fit for cultivation. The far-famed cedars are visible from the top, standing at the foot of the steep declivities of the higher division of the mountain. They form a small wood, which stands on the uneven ground of the mountain. Burckhardt mentions that he counted nearly 400 trees of all descriptions. Of the oldest and best-looking trees there are about eleven or twelve, distinguished by having the foliage and small branches at the top only, and by four, five, and even seven trunks springing from one base. They were covered with the names of travellers, one of which was dated in the seventeenth century. The trunks of the oldest trees were apparently dead. There were twenty-five large trees, about fifty middling ones, and 300 smaller and young trees.

The country that lies between the two ranges of Libanus and Anti-Libanus is inhabited by an industrious race of cultivators; and throughout its whole extent are scattered small towns, with from 100 to 200 houses, and everywhere the most splendid remains of antiquity, which have drawn to this unfrequented region a numerous concourse of European travellers. It is a plain, which is divided into the territory of Bekaa (signifying a mulberry tree, from the number of those trees which grow on it, and which form the wealth of the natives), and the territory of Baalbec. On the eastern side it comprises the mountain of Anti-Libanus to its top, and on the western side the Libanus range, also to its summit. Northward the valley widens considerably, as the range of Anti-Libanus takes an eastern direction, where it terminates. This valley is fertile; and Burckhardt mentions that, twelve years before his arrival, the plain and a part of the mountain were covered, to the distance of half a league from the town, with grape plantations; but, owing to the oppressions of the government, they are now destroyed, and the inhabitants, in place of eating their own grapes, are obliged to import them from other parts.[1] Wherever they are treated with ordinary humanity and justice, which is the case in some parts, they are industrious, and, though not rich, independent. They live in houses of mud, supported with beams of pine-wood and earth, with which the flat roofs of the houses are covered, but which are so feeble, that deep snow, which falls in winter, would break through, if it were not carefully removed by the inhabitants every morning. They generally depend for subsistence on the cultivation of their vineyards and a few mulberry plantations, or on their fields, in which grain is produced; and partly on a trade which they carry on in Kourdine sheep; also on their shops, and on some trifling manufactures in cotton cloths, which they use as shirts, or as gowns when dyed blue. They likewise fabricate woollen mantles. This hilly district is abundantly watered by rivulets: almost every village has its spring, all of which descend into the valley, where they generally lose themselves, or join the Liettani, between Baalbec and Zahle, which is one of the most considerable towns in this territory, containing about 5000 Catholic Greeks, with a few Turkish families. There are several other towns scattered over the country; and to these the oppressed inhabitants sometimes fly from the exactions of the pacha of Damascus, or other petty tyrants who have at different times ruled over most parts of Syria.

The land in this valley of Bekaa, between the two great mountain ranges of Libanus and Anti-Libanus, is not so well cultivated as on the opposite or western declivity of the mountain, probably because the industrious cultivator is not so sure to reap what he may industriously sow. About one sixth of the land only is cultivated, the remainder being left for pasture to the wild Arabs. The proprietors of the soil are mostly noble families of Damascus, which lies about sixty or a hundred miles to the east, or of the Druse mountains, by whose exorbitant demands the peasant cultivators are scarcely left a bare subsistence. The whole of this valley, with occasional rocky spots, is fertile and productive. The inhabitants consist of various races; the majority are Turks; one fifth are Catholic Christians, with an intermixture of Arabs, who migrate along with the season, in order to find pasture for their flocks; and also of Druses and others. In other districts, the greater part of these mountaineers are Christians. In Bshirrai, near the northern termination of the range, they are all Christians; and in other parts three fourths are Christians, mostly of the Greek church. The Arabs generally pass the winter months on the sea-shore about Tripoli, Jebail, and Tartous, though they have no fixed habitations. They have the true Bedouin features, and they have the general propensity of their tribe to thieving. Their property, besides camels, consists in horses, cows, sheep, and goats. The country in many parts, from its abundant springs and the heavy dews which fall, produces a luxuriant pasturage; and here the various wandering tribes, the Arabs, Turkmans, and Kourdines, pasture their cattle. These latter bring annually into Syria from 20,000 to 30,000 sheep from the mountains of Kourdistan, the greater part of which is consumed in Aleppo, Damascus, and the mountains, as Syria does not produce a sufficient number for its own consumption. The Kourd sheep-dealers first visit with their flocks Aleppo, then cross the Anti-Libanus mountains, Hama, Homs, and Baalbec; and what they do not sell on the road they bring to pasture on the Syrian mountains, whither the inhabitants of the neighbouring towns repair, and buy up thousands of them, which they afterwards sell in retail to the peasantry. The country produces in abundance the mulberry, the vine, and the olive. The silk-worm thrives remarkably well, and the inhabitants rear a large produce of silk. Tobacco of a very fine quality is also produced on Mount Libanus; as also honey throughout the whole of this mountain district. Fruit trees succeed remarkably, and walnuts and other fruits form an article of export. Oaks, pines, the spreading palm, and other trees, flourish; and Burckhardt mentions that he had seen the former more than sixty feet high. Galls and medicinal plants are also produced in these mountains, and are exported from Tripoli and other ports. The mineralogy of this country has been little explored. Burckhardt, from whom we derive most of our knowledge, mentions, that on digging he found several pieces of a metallic substance, which he took to be native amalgam of mercury. He also inferred from what he heard that cinnabar was to be found. The ground all around the village of Hasbeya he discovered to be impregnated with iron. Here are also numerous wells of bitumen, situated on a chalky hill, below the surface of which bitumen is found in large veins.

---

[1] Burckhardt's Travels in Syria and the Holy Land, p. 10.

The pits are from six to twelve feet in diameter, into which the workmen descend by a rope and wheel; and in hewing out the bitumen they leave columns of that substance at different intervals, as a support to the earth above. There are upwards of twenty-five of these pits, most of which have been abandoned, and are overgrown with shrubs. It is only in the summer months that they are worked, on account of the emir, who monopolizes the produce, and sends it to the merchants of Damascus, Beirout, and Aleppo. The wild animals found here are the wild boar, the wolf, the ounce, and some say the lion, on the banks of the upper Jordan. Hares are seen in abundance.

The number of Christian sectaries which exist in this rude country is not more remarkable than their virulence against each other. Greeks, Catholics, Maronites, Syrians, Chaldeans, and Jacobites, have all their respective parishes and churches. They are furious against each other; and each sect has the folly to believe that its church would flourish on the ruins of its heretic brethren. The principal hatred subsists between the Catholics and the Greeks. Of the latter many thousands have been converted to the Catholic faith; all Catholics, the Maronites excepted, having formerly been of the Greek church in Aleppo, Damascus, and in all the intermediate country. Communities of the original Latin Christians are only found around Jerusalem and Nablous. The Catholic bishop resides at Zahle; and his diocese comprises the whole Christian community in the Bekaa, or valley between the two great Libanus chains, and the adjoining villages of the mountain.

Towards the north the mountains of Syria approach nearer the sea, and leave scarcely any intervening plain. The city of Antioch, on the Orontes, is surrounded by mountains of great height, the different ranges from the interior terminating in this quarter, and leaving open before it a valley from ten to fifteen miles wide, presenting the appearance of an elevated plain, which is said to continue eastward all the way to Aleppo. The southern boundary of this valley is the mountain range of Jebel Okrah, the steep sides of which seem to rise abruptly from the sea, and continue their ascent until they terminate in its gray and bare peak at the height of perhaps 5000 feet from its base. Its northern boundary is the mountain range called Jebel Moosa, the western extremity of which slopes down into a cape, at the distance of about six miles north of the discharge of the river Orontes into the sea, and its even summit runs along eastward from the coast until it loses itself among irregular ranges of hills. The inner and eastern points of these different ranges gradually approach each other till they seem to meet, leaving a triangular valley or plain between them, its base-line being the sea-line, and its whole length from eight to ten miles. It is nearly in the centre of this valley that the Orontes takes its course; and its northern bank is occupied by corn-fields, mulberry grounds, gardens of fig-trees, and detached cottages all excellently built, and mostly of two stories, with sloping and tiled roofs. The upper valley, through which this river flows, is also thickly wooded and highly cultivated, the stream distributing fertility along its winding way. Buckingham celebrates the beauty of the country on the banks of the Orontes, and in the vicinity of the town of Homs. "Our ride," he says, "was through one continued park of indescribable beauty; and although chiefly over a level ground, yet, by the profusion of its wood, and here and there some gentle eminences, the landscape varied at every point of view. The state of agriculture here, too, was more perfect and more flourishing than we had hitherto seen it elsewhere. The fields were free from weeds and stones, and many of them were enclosed with light fences of twig-work. Some of the barley was nearly ripe for the perennial harvest; and other grounds were tilling by four ploughs in succession, each followed by a sower distributing the grain from a basket for the autumnal one. Fine fat cattle were seen in numerous herds, with some few buffaloes among them, and all wore an appearance of wealth, activity, and abundance."[1] Towards the north of Syria, on the coast, there is a great change from the mountain districts, in the appearance, dress, and manners of the inhabitants. "All," says Buckingham, "was now decidedly Turkish. The peasants were of a different physiognomy as well as dress; and one marked peculiarity of contrast was their wearing long boots reaching to the knees, of black leather, and shaped like European ones, without drawers; while the Arabs of Syria all wear long full drawers, and either red shoes, or, as often happens, go barefooted."[2] The language also is Turkish instead of Arabic. The country thence eastward, as far as Aleppo, is mountainous, with intervening valleys. Southward, the mountain range of Libanus recedes from the coast, leaving champaign country, diversified with lower hills. From Aleppo, as far south as Damascus, the hilly region prevails, being the eastern declivity of the Libanus mountains.

The immediate neighbourhood of Damascus is known under the name of El Ghautta, which comprehends a district of about thirty square miles; it contains upwards of eighty villages, and is one of the most fertile districts in Syria. In the south is a rocky district called the Ledja, which is from two to three days' journey in length by one in breadth, and is inhabited by several tribes of Arabs, who breed a vast number of goats, which easily find pasturage among the rocks. A few of them also keep sheep and cows, and cultivate the soil in some parts of the Ledja, where they sow wheat and barley. This district is divided between the inner and the outer Ledja. The inner consists of a labyrinth of rocks, through which the Arabs alone have a clue; some of them are twenty feet high, and the country is full of hills. Trees are numerous among the rocks. The most common are the oak, and the bitter almond tree, from the fruit of which is extracted an oil which is in great request among the inhabitants. There are no springs in any part of this stony district; but water collects in great quantities in the hollows and in the cisterns, where it is kept through the summer. Millstones are cut horizontally out of the rocks, and are carried to be finished at Ezra, and the other towns in this district. The camel is commonly met with in the Ledja, and walks with a firm step over the rocky surface. In summer he feeds on the flowers or dry grass of the pasturing places. This district, like all the rest of the country, is full of ruined towns and cities, containing the remains of large edifices and innumerable inscriptions, with columns, pillars, and all the finest remains of ancient architecture.

To the south-west of this barren and rocky territory lies the extensive district of the Haouran, which is bounded on the south-west by the mountain chain which is prolonged southward, and here spreads out into a mass of mountains, which extend still farther southward into Palestine. On the south-east, where the farthest inhabited villages are Bosra and El Remtha, the Haouran borders on the desert. It lies between different ranges of lofty mountains, and is a plain diversified with gentle elevations, the same levels being nowhere of long continuation, though still not so much above or below each other as to destroy the general character of an irregular and undulating plain, in which there is nothing that deserves to be called a hill on its whole surface. The eminences that occasionally break the continuity of the surface, are mostly small veins of rock projecting above the surface; and these appear in all cases to have been selected for the sites of towns, for the sake of securing a commanding position, a freer air, and a drier soil. This plain is fertile in corn, and is considered as the granary of Syria. But it is liable to severe droughts, under one of which calamities it was suffering when it was visited by Buckingham in 1824. In the eastern hills among the Druses, and in the mountains of Jordan, both rain and snow had fallen; and thither many distressed families had taken refuge from the prevailing distress. Buckingham, when he was in this country, had a view of this extensive district from the hills to the west; and he could perceive, that though lower than the elevated country of Belkah, it was a table-land on a high level, measuring from the surface of the lake of Tiberias, as the tops of the lofty hills which form the eastern boundary of that lake appeared but on a level with the surface of this plain, so that the lake must have been much lower. To the east a range of hills, inhabited by the Druses, bounds the plain. These hills are of an unbroken outline, and not much elevated from the plain, although their summits penetrate the line of perpetual snow. To the north-east the land gradually rises, and is lost in an even horizon of high plains. To the north the view is bounded by another range of snow-clad mountains, called also the Mountains of the Druses. On the north-west there is a still higher range, called Jebel-el-Tely, covered with snow, and extending north-east and south-west; and in this last direction the northern points of the Asswete and the Adjeloon ranges show patches of snow amidst thick forests of evergreen wood. Beyond these, again, is another great plain or table-land, on a higher level, to the eastward, and said to be in all respects equal to the Haouran in the fertility of the soil and the abundant remains of a numerous population.

[1] Buckingham's Travels in Syria, p. 507.

[2] Buckingham's Travels among the Arab Tribes, chap. xxvi. p. 541.

Buckingham laments that so fine a country should be in the possession of such barbarous inhabitants, and abandoned, from their negligence and tyranny, to sterility and desolation. "On the mountains and plains," he adds, "of these districts of Belkah, Adjeloon, and Haouran, extending from the Dead Sea to the sources of the Jordan north, and from the banks of that river to the extreme limits of the cultivable land on the east, there would be room for a million of human beings to form a new colony, who would enrich every country that was on their borders, and would form a centre from which industry, arts, science, and morals, might extend their influence, and irradiate regions now the prey of ignorance, rapine, and devastation."[1] Among the hills, horses, mules, and asses, are bred as beasts of burden; but in the plain of Haouran numerous herds of camels are to be seen.

To the west of the Haouran the country becomes mountainous, but is still extremely fertile, and interspersed with numerous valleys. To the east of the river Jordan, from the lake of Tiberias to the Dead Sea, and from Oom Kais to Heshbon, its fertility is great. In the mountain districts of Belkah and Adjeloon, the woody scenery can scarcely be surpassed in beauty. The valleys abound with corn-fields and olive-grounds; the upland slopes of the hills are planted with vines, and the summits of the mountains are clothed with trees of the coldest regions. "The climate," says Buckingham, "is really delightful; a clear, deep, blue sky, a pure air, a warm summer in the valleys and plains, a snowy winter on the mountain tops, with all the finest shades of gradation between these two extremes, furnish every variety of temperature and atmosphere that can be desired by man. Indeed this portion of the country, included in the districts of Belkah and Adjeloon, on the east of the Jordan, is as superior to the promised land on the west of that stream, as the most romantic and beautiful parts of Devonshire are to the bleak hills and barren heaths of the adjoining county of Cornwall."[2]

Syria is inhabited by a mixture of various races, with their peculiar manners and modes of faith. The coast and the seaport towns, more especially towards the north, and Aleppo and Damascus, exhibit a population chiefly Turkish, with Turkish manners, costume, and language. But the mountain regions, the countries on the Libanus and the Anti-Libanus range, the intervening valleys, the eastern declivity towards Aleppo and Damascus, and to the south the districts of Ledja, the Haouran, and the countries to the west of the Jordan, are inhabited by Turks, Druses, Christians, and Arabs, some wanderers and robbers, and others following the pastoral life, or enacting alternately the shepherd and the robber as opportunity offers. Civil order or law is but very imperfectly maintained in those unsettled countries. Some districts purchase an exemption from Arab robbery, by paying a contribution, on the same principle as the Scotish Lowlanders formerly paid the contribution of black mail to the mountain robbers of their country. Under the former dominion of the Turkish pachas no regular police was established: there was no security to the traveller, either for life or property; and in the mountain districts, and to the eastward of them, traders, in journeying to Aleppo or Damascus, were forced to associate in large caravans in order to repel the herds of robbers with which the roads were infested. Since the country has come under the dominion of the pacha of Egypt, it has been the scene of rebellion, owing to his oppressions; and the disorders which have ensued cannot fail to encourage the trade of robbery and violence. It is not possible that the condition of the country can be improved when civil war continues to rage within its borders.

The Druses, who are spread over all Syria, more especially in its mountain tracts, are a very peculiar race; and little has yet been discovered of their religion and its occult rites. Their priests maintain an impenetrable silence on these subjects; and when strangers question any of the lay-members of this curious sect, they relate numberless fables, which find their way into books of travels, and thus errors are propagated. A very curious remnant of Egyptian superstition is said to prevail in Mount Libanus, among those Druses who assume the name of okkals, namely, divine honour paid to a calf; and the worship of Venus by the most licentious rites is reported to be practised among them. They are indifferent to all the outward forms of religion, and admit into their temples as objects of adoration whatsoever has been venerated by heathens, Jews, Christians, or Mahommedans. They are reported to worship all the prophets, especially Isaiah and Jeremiah, as well as Christ and Mahommed; and at set times the okkals, who cultivate mysteries, elevate within their places of worship a molten idol made of gold, silver, or brass, which has the form of a calf. According to the report, prostrations are made before this idol, and these are followed by a promiscuous intercourse of the different sexes. That they are not so indifferent as has been reported to different systems of religion, appears from their hatred and contempt of Mahommedanism, while they behave with great benevolence and friendship to Christians, whose faith they respect. The okkals or akauls, the priests of the Druse religion, are distinguished by a white turban, and the peculiarity of the folds in which they wear it. They are subjected to self-denial; they are not permitted to smoke tobacco; they never swear, and are reserved in their manners and conversation. They pray in their chapels, but not at stated periods. These are built in some sequestered spot, and none but Druses are allowed to enter them. They affect to follow the doctrines of Mahommed; few, however, pray according to the Turkish forms. They fast during Ramadan in the presence of strangers, but eat at their own houses even of the flesh of the wild boar, which is frequently to be found in the mountain districts which they inhabit.[1] They are industrious cultivators, and live comfortably where they are not oppressed by Turkish extortion. Buckingham mentions, that where he was entertained by one of them at supper, they had a chimney, as in England, blazing with an excellent fire. The men were all stout, handsome, clean, and well dressed, and the children among the best-looking he had seen in Syria.[2] They speak the Arabic language, but in every thing else they are a distinct race. Their physiognomy is particularly marked; and from the visible difference, Dr Clarke was enabled to select one of the Druses from the midst of a party of Arabs. According to the testimony of this traveller, they are distinguished by a certain nobleness and dignity of feature, a marked elevation of countenance, and superior deportment, accompanied by openness, sincerity, and engaging manners. They are much esteemed for their probity and mildness of disposition.[3]

[1] Buckingham's Travels in Syria, p. 228.

[2] Buckingham's Travels among the Arab Tribes, chap. viii. p. 141.

The Bedouin Arabs wander over all Syria. They are of two classes; those who do not fix their habitation to any district, but who range over the whole country; and those whose wanderings are confined within certain bounds. The Bedouins of the Haouran were formerly bound to join the troops of the Turkish pacha when that country was under the dominion of the Porte; but they were in general guided entirely by the advantage which they were likely to derive from the contest. The Arab tribes were formerly subject to an annual tribute, which was levied on each tent, according to the wealth of its owner. It was often refused by the poor or refractory Arabs. Those of the Ledja, the district already described, on the north of Damascus, often withheld the tribute, in the confidence that the recesses of their abodes could not be forced. But they were often reduced by the want of water; when, their own springs failing, they were obliged to approach the perennial springs of other districts. The Arabs of the Haouran act as shepherds for the people of the plains, who intrust to them in summer and winter their flocks of goats and sheep, which they pasture during the latter season among the rocks of the mountains. In spring they account for the flocks to their owners, who sell a part of them at Damascus. They receive for their trouble one fourth of the lambs and kids, and a like proportion of the butter. Casual losses in the flocks are borne by both parties. These are the Arabs who are comparatively stationary. The wandering Arabs cover the whole of the plain of Haouran, whither they come in swarms from the desert in May, and remain until September. On their arrival, the resident Arabs who may happen to be at war with them conceal themselves in the mountains, with all the recesses of which long experience has made them familiar. Till within a few years these Arabs were the constant carriers for the Hadji pilgrims on their road to Mecca, and made yearly contracts with the pacha, by which they were considerable gainers, as well as by the fixed tribute which they levied on the pilgrim caravans, and by the nightly plunder of stragglers and loaded camels on the march.

The Arabs are generally of a short stature, thin visage, scanty beard, and brilliant black eyes; while the Druses are taller and stouter, with a long beard, and a less piercing look. The Turks and Christians of the Haouran live and dress alike, and religion seems no source of difference between them. The Christians, as they recede from the sphere of supreme authority, enjoy a degree of boldness and freedom unknown in the Turkish cities or in their vicinity, or throughout the lower and more populous districts. When quarrels arise in these mountain regions, a Christian fears not to strike a Turk, or to execrate his religion; a liberty which, in the Syrian towns, would expose the offender to the penalty of death, or to a heavy pecuniary fine. This liberty which Christians enjoy in the Haouran and in other remote and less frequented districts, is supposed by Burckhardt to arise from the common sufferings and dangers which they encounter in defence of their property; and it is strengthened by the Druses, who show equal respect to both religions. Buckingham ascribes this diminution of religious bigotry and intolerance to the nearly equal mixture of Mahommedans and Christians. The prohibition of the Christians and Jews to wear the same gay colours as the Mahommedans, to use the salutation of peace, or to employ the oaths and ejaculations peculiar to the faith of Islam, which is enforced wherever the authority of Arab or Turkish governors extends, does not take effect in the mountain districts of Syria, where the two religions are on a footing of equality.

There is little distinction between the richest and the poorest of the Druses in their mode of living. In newly-built villages the whole family, with all its household furniture, cooking utensils, and provision chests, is commonly huddled together in one apartment; but where the ancient buildings, which were raised by the more civilized race that inhabited the country in the age of the Romans, are occupied, they afford spacious and convenient dwellings of three or four apartments for each family. The country, as has been already mentioned, is covered with these dwellings, constructed very curiously of stone, and with other wonderful memorials of ancient grandeur. Granite pillars, hewn blocks, excavated sepulchres, Roman theatres and temples, and other works of masonry, all testify the great works of former days. The houses are all built of solid stone; and from the scarcity of wood a singular kind of masonry has been restorted to, the stones being interlocked into each other by a kind of dove-tailing, and thus very strongly united without cement. They have small windows, both of the square and circular form in the same range. In many of these dwellings there were massy folding doors of stone, which were moved on stone hinges, and of which the remains are still to be seen. Some are fastened by horizontal bars of stone, and others by perpendicular ones in the inside of them, and lodging each end in the massy framework of the door on either side, or above and below, as the position of the bar required. The want of wood for building rendered it necessary to use very large stones for some parts of the edifices, such as beams for the roofs and doors. These houses are large, having several spacious apartments; and they are still used by the inhabitants, being constructed of such durable materials as to resist decay.

The Turkmans are a barbarous race, with pastoral habits, who range over the plains west-north-west of Aleppo, and the mountains by which it is bounded on the west; the average breadth of which, including the numerous valleys which intersect them, may be estimated at from fifteen to twenty miles. They lose themselves in the plain of Antioch, which is bounded on the opposite side by the chain of high mountains that extends along the southern coast of the gulf of Scanderoon. The plain of Antioch is watered by the river Afrin, which is full of carps and barbles; but the Turkmans have no implements for fishing. The valleys among the mountains are besides watered by numerous other rivers; and here is a small lake formed by the river Goul, which is so full of fish that the boys kill them by throwing stones at them. Here are also warm springs, which were seen by Burckhardt, strong-

ly impregnated with sulphur, in which the thermometer rose to 102°. Those tribes of the Turkmans appear in their winter-quarters in the plain of Antioch at the end of September, and depart towards the middle of April, when the flies of the plain begin to torment their horses and cattle. They then begin to direct their march towards Marasch, and remain in the neighbourhood of that place for about a month; thence they reach the mountains to the east, where they pass the hottest summer months; and in autumn they return by the same route towards Antioch. They live in tents and in huts. Those tents are always surrounded by four others, in which live the Fellah families, who cultivate the land. These are the remaining peasants of abandoned villages, or some poor stragglers from the mountains of Kurdistan, who live wretchedly; and when they succeed in scraping together a small pittance, their Turkman masters contrive to take it from them under pretence of borrowing it.

Syria is a country of ancient renown, and connected with many interesting historical recollections. In the early periods of the Jewish history, it was a powerful state, of which Damascus was the capital. Phœnicia, the great commercial state of those ancient times, flourished in Syria, and sent out colonies to other countries. Syria was, after the death of Alexander, erected into an extensive monarchy under Seleucus, one of his lieutenants. It comprehended the whole west of Asia, and under Antiochus maintained a long and doubtful conflict with the Roman power. Under the Roman emperors Syria was the seat of luxury and wealth, and Antioch, the capital, was, next to Rome and Alexandria, one of the first cities in the empire, famed for its riches and splendour. Syria, during the decline of the Roman empire, was overrun by barbarous hordes, and fell under the dominion of the Saracens. It was the great theatre of contention between the crusading armies and those of the Moslems; and a long and bloody contest, signalized by deeds of valour on both sides, terminated in the triumph of the infidels; when Syria was finally absorbed in the Turkish empire, of which it formed one of the richest and most valuable provinces. It was ruled by the provincial authority of the pachas, several of whom, in the increasing weakness of the Turkish sway, set up the standard of independent power. Among the earliest of these was Fackerdin, the emir of the Druses, who made himself master of Beirout, and successively of all the towns on the Syrian coast. He was at last defeated and slain by the Turkish force sent against him; and his posterity continued to administer the affairs of the Druses as vassals of the Porte. Daher, a powerful Arabian scheik, contended for independent power so successfully with the sultan, that for a long time he was obliged to grant him an annual lease of his dominion. He was also subdued by a powerful army sent against him by the Porte, and was put to death. He was succeeded by the well-known Dsjezzar Pacha, who acquired a power almost equally independent, but who, unlike the former pacha, whose administration was mild and just, was a fierce and savage tyrant. His reign was rendered remarkable by the invasion of Syria by Bonaparte, and by his memorable defence of Acre, along with the British under Sir Sidney Smith. After the death of Dsjezzar, Soleiman was appointed pacha; and it was about this period that Syria was first threatened with an invasion by the Wahabis, whose power had been extending for some years, and who would no longer permit the great armed caravans to proceed to Mecca from Damascus. Yussuf Pacha succeeded, and was equally unsuccessful in repelling the incursions of the Wahabis, who, advancing through the Syrian desert, spread terror to the gates of Damascus. The important task of crushing the rising power of this formidable sect was at length undertaken by Mehemet Ali, the present pacha of Egypt, who sent Ibrahim with a numerous force, and a vast retinue of camels and other beasts of burden, with large supplies, and succeeded, after many bloody conflicts, in taking their capital, and Abdallah their chief, who was sent prisoner to Constantinople, and there beheaded.[1] Syria, after the extinction of the Wahaby power, was ruled as before by Turkish pachas, the vassals of the Porte, who oppressed the country by exactions, and left the poor peasantry scarcely a bare subsistence. When a just administration, with which they are occasionally blessed, left them the produce of their fertile soil, they were prosperous and happy, as they were proportionably miserable under those cruel tyrants, in whose hands power was only used for extortion.

But a new era was now approaching, when Syria, in the progressive decline of the Turkish dominion, was to pass under the yoke of a new and even more severe task-master. The pacha of Egypt, Mehemet Ali, had been long aspiring at independent power; and having collected and disciplined a powerful army, he at length threw off the mask, and in October 1831 invaded Syria by El Arish, and after taking possession of Gaza and Jaffa, he laid siege to St Jean d'Acre, the memorable scene of so many sanguinary conflicts. The place was strong, and resolutely defended by Abdallah Pacha. The siege had continued three months, during which the town was reduced to a heap of ruins. The Egyptian army had also suffered severely. In the mean time, Osman, the bey of Tripoli, having collected a force of 5000, proceeded to the attack of Tripoli, on the sea-coast. Ibrahim hastened with 5000 troops and six pieces of artillery to this new scene of action, and on the 31st of March 1832 succeeded in putting Osman to flight after a severe engagement. He retired across the mountains to Hamah; and Ibrahim following, encamped on the plains of Homs, where he was attacked on the 15th of April by a Turkish force, and after a drawn battle, retired on Baalbec. In the mean time Mehemet Ali, impressed with the importance of gaining possession of Acre, sent reinforcements from Candia; and Ibrahim resuming the command, pressed the siege with redoubled vigour, and on the 15th of May the place capitulated after a severe struggle, Abdallah and the garrison being made prisoners of war. Mehemet Ali, following up his success, advanced on the 8th of June on Damascus, which he entered on the 14th. He was joined by the Christian population of Mount Lebanon, and by their aged emir with 5000 men. The victorious army resumed its march northwards for Aleppo; and at Homs, on the head streams of the Orontes, he was encountered by a Turkish force of 20,000 men, which was completely routed, with the loss of tents, provisions, ammunition, and thirty-one pieces of cannon. Ibrahim now divided his force, sending one detachment to Antioch, and advancing with the other towards Aleppo. Hearing that the Turkish army had now entered Syria under Husseyn Pacha, he proceeded to meet the enemy. The Turkish position was one of great natural strength, accessible only by a defile. Troops were posted along all the heights, which were besides crowned with artillery. The Egyptian army reached the pass on the 28th of July; and the following morning, having silenced the enemy's batteries by his superior fire, Ibrahim carried the heights by main force. The victory was complete; the loss of the Turks amounted to 13,000 men, and forty pieces of cannon were left on the field. The fruit of this victory was the surrender of Antioch, and the submission of the whole north-eastern portion of Syria. Another battle was fought on the 21st of December 1832, when the Turkish army, amounting to 40,000 men, with sixty pieces of cannon, was entirely routed and dispersed.

---

[1] See article ARABIA in this work.

The sultan was now completely humbled; and after various delays and negociations with Russia, a treaty was finally concluded, which ceded the dominion of Syria to Mehemet Ali.

Syria has been ruled by Mehemet Ali with the most tyrannical cruelty. The conscriptions both for the army and for his military works have been enforced with the most unheard-of brutality. At Damascus the houses were surrounded in the night by troops, and every man capable of bearing arms was carried off. Still greater outrages took place at Beirout, where the inhabitants, Turks, Jews, and Christians, were seized or knocked down in the streets; the houses broken open, and all dragged indiscriminately to prison, and there plundered and otherwise maltreated. His conscriptions and rigorous exactions produced insurrection in various quarters of the country. These were soon suppressed, and were followed by severe vengeance. The Druses were decimated, and their villages burned. The Ansaries, who were driven to resistance by oppression, were indiscriminately slaughtered, though they implored forgiveness. Towards the close of 1837, the Druses again rose in arms to resist the intolerable cruelty of Mehemet Ali. They gained a signal victory over a force of 20,000 troops under Achmet Pacha, who was driven back with great loss by the Druses, advantageously posted on the mountains. But new armies being sent, the Druses were finally defeated, and compelled to seek refuge in the recesses of the mountains.

In the mean time the Porte, stung by recent humiliation and the loss of Syria, was preparing for a new war; to which the hesitation of Mehemet Ali in paying his tribute, and his threatened declarations of independence, afforded a sufficient motive. Mehemet Ali on his part reinforced his armies; and although the European powers, namely, Great Britain, Russia, France, and Austria, interposed to maintain peace, the armies at length encountered, when victory again declared in favour of Mehemet Ali, whose way was now open to Constantinople, when the vigorous interposition of the European powers enforced an armistice, with a view to establish a lasting peace. Since this period the combined influence of the same powers has been exerted to settle these eastern disputes, and, as is understood, to maintain the integrity of the Turkish empire by the cession of Syria to the Porte. Mehemet Ali refuses to yield the hereditary sovereignty of this country, the fruit of victory and his right by conquest. The European powers are engaged in anxious discussions to effect a settlement of these disputes, and numerous fleets are assembled in the Mediterranean to give weight to their interference.

How far the interest or honour of those powers, and more especially of Great Britain, is so directly concerned in the integrity of Turkey as to warrant such actual interference, and the maintenance of expensive armaments, may well be questioned. The Turkish empire has been long verging to decay; and can no longer maintain supreme rule over its subordinate governors, who, taking advantage of its weakness, assume independent power. This is a necessary step in the natural progress of decay which no foreign aid can avert; nor is it easy to perceive any rational ground for the interference of Great Britain, by means of expensive armaments, in those distant disputes, the result of which cannot affect her safety. The rise of an independent power in the east, such as Egypt, cannot possibly be prejudicial to European interests; and for what purpose therefore set in motion such expensive political machinery to arrest the natural progress of events? Even if Turkey were to fall under the extending sway of Russia, of which there is no immediate prospect, it is doubtful whether this accession of territory would add to her solid strength; whether it would render her a more formidable enemy, held as it would be by the uncertain tenure of recent conquest; and whether therefore it is not the wiser policy to remain quiet, watching the course of events, than to provide by expensive preparations against dangers which may only exist in the fancies of speculative politicians. It is this system of watchful anticipation, and of chimerical anxiety about the balance of power, which has plunged Great Britain into so many useless wars, and has overwhelmed her with debt; and the danger is, that the same course followed in a season of profound peace will increase her burdens, until she sink at last under the accumulating load. (F.)

SYRIAM, a town of the Birman empire, in the province of Pegu, on the banks of the Appoo river, where were formerly situated several factories of the Europeans. The British factory was destroyed during the wars between the Birmans and the Peguers. Long. 96. 17. E. Lat. 16. 49. N.

SYRINGE, a well-known instrument, serving to imbibe or suck in a quantity of fluid, and to squirt or expel the same with violence. The word is formed from the Greek *σύριγξ*, *a pipe*. A syringe is only a single pump, and the water ascends in it on the same principle as in the common sucking-pump.

SYSTEM, in general, denotes an assemblage or chain of principles and conclusions, or the whole of any doctrine, the several parts of which are bound together, and follow or depend on each other; in which sense we say a system of philosophy, a system of divinity, &c. The word is formed from the Greek *σύστημα*, *composition*.

SYSTEM, in *Music*, signifies an exposition of all the sounds employed in composition, considered theoretically and practically, melodically and harmonically. The ancient Greek melodic system was divided into tetrachords; the modern melodic and harmonic system is divided into octaves. The Guidonian system was divided into hexachords. The most modern system of harmony, which originated in the sixteenth, seventeenth, and eighteenth centuries, is founded upon a system of tonality different from that employed prior to these periods, as will be shown under the article TONALITY. For some account of harmonic systems, see MUSIC.

SYSTYLE, in *Architecture*, that manner of placing columns where the space between the two shafts consists of two diameters or four modules.

SYZYGY, SYZYGIA, in *Astronomy*, a term equally used for the conjunction and opposition of a planet with the sun. The word is formed from the Greek *συζυγία*, which properly signifies *conjunctio*. On the phenomena and circumstances of the syzygies a great part of the lunar theory depends. See ASTRONOMY.

SZARVAS, a large town of the Austrian kingdom of Hungary, of the circle of the Farther Theiss, and the district of Bekesch. It stands on the river Koros. It is chiefly inhabited by the Saxon race, who have there a Lutheran church, and several institutions for education, chiefly on subjects relating to the knowledge and promotion of arts, manufactures, and agriculture. It contains 820 houses, with 8600 inhabitants. Long. 20. 26. 19. E. Lat. 46. 52. 30. N.

SZEGEDIN, a large city of the kingdom of Hungary, in the province of the Farther Theiss, and circle of Songrab, of which it is the capital. It stands on the river Theiss, where that stream is joined by the Maros. It is well built and strongly fortified, is the seat of a Greek propope, of a Piarist college, and of a Catholic gymnasium.

From its situation on a great river, it carries on extensive trade both upwards and downwards, but chiefly in the products of its soil. Here they build numerous boats and barges, which are loaded with tobacco, corn, wood, and some manufactured goods both of wool and cotton. The tobacco raised near the city is highly valued in all the Austrian dominions, and the quantity annually exported is said to exceed 60,000 quintals. The public buildings have nothing remarkable, but the city contains 4600 dwellings, and the inhabitants now amount to 32 500 having increased to that number from 25,690 since the year 1817. Long. 20. 4. 57. E. Lat. 46. 15. 15. N.

SZIGETH, a town of the kingdom of Hungary, in the province of the Farther Theiss, the capital of a circle of the same name. It stands at the influx of the river Itza to the Theiss. It contains a Catholic college, and churches for that sect, one for the Lutherans and one for the Unitarians, with 6850 inhabitants. The greater part of the kingdom is supplied with salt from this place. Long. 24. 16. 25. E. Lat. 47. 56. 8. N.

T.

T, or t, the nineteenth letter and sixteenth consonant of our alphabet; the sound of which is formed by a strong expulsion of the breath through the mouth, upon a sudden drawing back of the tongue from the fore-part of the palate, with the lips at the same time open. The proper sound of *t* is expressed in most words beginning or ending with that letter; as in *take, tell, hot, put*. *Ti* before a vowel has the sound of *si*, or rather of *shi*, as in *creation*, except when *s* precedes, as in *question*; and derivatives from words ending in *ty*, as *mighty, mightier*. *Th* has two sounds; the one soft, as *thou, father;* the other hard, as *thing, think*. The sound is soft in these words, *then, thence*, and *there*, with their derivatives and compounds; and in the words *that, this, thus, thy, they, though;* and in all words in which *th* comes between two vowels, as, *whether, rather;* and between *r* and a vowel, as *burthen*.

In abbreviations, among the Roman writers, T. stands for *Titus, Titius*, &c.; Tab. for *Tabularius;* Tab. P. H. C. *Tabularius Provinciæ Hispaniæ Citerioris;* Tar. *Tarquinius;* Ti. *Tiberius;* Ti. F. *Tiberii filius;* Ti. L. *Tiberii libertus;* Ti. N. *Tiberii Nepos;* T. J. A. V. P. V. D. *tempore judicem arbitrumve postulat ut det;* T. M. P. *terminum posuit;* T. M. D. D. *terminum dedicavit;* Tr. *trans, tribunus;* Tr. M. or Mil. *tribunus militum;* TR. PL. DES. *tribunus plebis designatus;* TR. AER. *tribunus ærarii;* TRV. CAP. *triumviri capitales;* T. P. or TRIB. POT. *tribunicia potestate;* Tul. H. *Tullus Hostilius*. Among the ancients, T, as a numeral, stood for *one hundred and sixty;* and with a dash at top, thus T̄, it signified *one hundred and sixty thousand*. In music, T stands for *tutti*, "all, or altogether."

TA, a city and fortress of China, of the second rank, in Sechuen. Long. 107. 15. E. Lat. 36. 55. N. Also the name of a river which falls into the Eastern Seas. Long. 121. 34. E. Lat. 36. 55. N.

TAAWIRY. There are two islands of this name, situated within the reef of the island of Otaheite.

TAB, a river of Persia, the ancient Arosis, which, rising in the mountains of Fars, divides that province from Khusistan, and falls into the Persian Gulf near Endian.

TABA ISLANDS, four small islands in the Eastern Seas, near the east coast of Borneo. Long. 118. 12. E. Lat. 2. 6. N.

TABABELLA, a town of Hindustan, in the province of Malwah, thirty-two miles west from Oojain. Long. 75. 20. E. Lat. 23. 16. N.

TABAS, a city of Persia, in the province of Khorassan. It is situated on the road from Herat to Yezd, 337 miles from the former, and 150 from the latter. It stands within a range of mountains, and contains 20,000 inhabitants. Tabas is also the name of a village in Anatolia.

TABBY, in *Commerce*, a kind of rich silk which has undergone the operation of tabbying.

TABBYING, the passing a silk or stuff under a calender, the rolls of which are made of iron or copper variously engraven, which bearing unequally on the stuff, renders the surface of it unequal, so as to reflect the rays of light differently, and to exhibit a representation of waves.

TABELLIO, in the Roman law, an officer or scrivener, much the same with our notaries public, who are often called *tabelliones*.

TABERNA, a city of Spain, in the province of Valencia, about six miles north-east from the capital, on the great road leading to Catalonia. It is on the sea-shore, in a district of great richness and fertility, and contains about 4500 inhabitants.

TABERNACLE, among the Hebrews, a kind of building, in the form of a tent, set up, by express command of God, for the performance of religious worship, sacrifices, &c. during the journeying of the Israelites in the wilderness; and, after their settlement in the land of Canaan, used for the same purpose till the building of the temple of Jerusalem. It was divided into two parts; the one covered, and properly called the *tabernacle;* and the other open, called the *court*. The curtains which covered the tabernacle were made of embroidered linen, of several colours. There were ten curtains, twenty-eight cubits long and four in breadth. Five curtains fastened together composed two coverings, which covered up all the tabernacle. Over these there were other two coverings; the one of goats' hair, the other of sheeps' skins. The holy of holies was parted from the rest of the tabernacle by a curtain fastened to four pillars, standing ten cubits from the end. The length of the whole tabernacle was thirty-two cubits, that is, about fifty feet; and the breadth twelve cubits or nineteen feet. The court was a spot of ground 100 cubits long, and fifty in breadth, enclosed by twenty columns, each twenty cubits high and ten in breadth, covered with silver, and standing on copper bases five cubits distant from one another; between which there were curtains drawn, and fastened with hooks. At the east end was an entrance, twenty cubits wide, covered with a curtain hanging loose.

TABERNACLES, FEAST OF, a solemn festival of the Hebrews, observed after harvest, on the fifteenth day of the month Tisri, instituted to commemorate the goodness of

Tablas Isle || Tabor.

God, who protected the Israelites in the wilderness, and made them dwell in booths, when they came out of Egypt. On the first day of the feast they began to erect booths of the boughs of trees, and in these they were obliged to continue seven days. The boughs were placed in the open air, and were not to be covered with cloths, nor made too close by the thickness of the boughs, but so loose that the sun and the stars might be seen, and the rains descend through them.

TABLAS Isle, one of the Philippines, situated due north of Luzon, thirty miles in length by three in average breadth.

TABLATURE (Ital. *Tabulatura*, or *Intavolatura*), an old species of musical notation by means of letters of the alphabet applied to a staff of four or more lines and their spaces, and most usually employed in music written for the guitar, or for instruments of the lute kind. It has long been disused, and is now generally unintelligible. For some explanations of Tablature, see Graham's Essay upon Music.

TABLE, a moveable piece of furniture, usually made of wood or stone, and supported on pillars or the like, for the commodious reception of things placed upon it.

TABLE Island, a small island in the South Pacific Ocean, so called by Captain Wilson. Long. 181. 54. W. Lat. 18. 54. S. This is also the name of several small islands in the Eastern Seas. Table Point is the southern extremity of Bali Island, in the Eastern Seas. Long. 115. 11. E. Lat. 8. 45. S.; also the eastern boundary of the south entrance into Bali Straits.

TABOO, a word used by the South Sea islanders, and nearly of the same import as prohibited or interdicted. It applies equally to persons and things, and is also expressive of any thing sacred, devoted, or eminent.

TABOR, a celebrated mountain of Palestine, situated to the south-west of Lake Tiberias, over which, and all the surrounding country, it commands an extensive prospect, about two leagues south-east from Nazareth, and nearly the same distance from Jordan. In shape it resembles a truncated cone. It is entirely calcareous, and is covered to the top with a forest of oak, and wild pistachio, and other trees, and a variety of plants. It is completely insulated from any of the neighbouring mountains, none of which is of equal height. It is estimated by Buckingham to be about 1000 feet above the adjacent country. It is covered in the morning, and during a great part of the day, with thick clouds, which disperse towards midday. A strong wind blows on it during the day; and Burckhardt mentions that more copious dews fall in the night than he had seen in any other part of Syria. Here this traveller found a single family of Greek Christians, who had resided on the top for several years. They rented the oval plain into which the summit is extended for about a quarter of a mile, at fifty piastres, and had retired to this remote spot to avoid paying taxes. Here are found the remains of a large fortress, the thick wall of which may be traced quite round the summit. The area of the plain is overspread with ruins of private dwellings, built of stone, of great solidity, and with the vestiges of churches, grottoes, and other ancient relics. There are no springs; but numerous reservoirs have been cut in the rock, two of which are still of service in supplying water. Mount Tabor is celebrated as the Mount of Transfiguration.

Tabor, a city of the Austrian kingdom of Bohemia, the capital of the circle of the same name, which extends over 1137 square miles, and contains 171,270 inhabitants. The city is situated on a hill near the river Luschnitz. It contains a very curious collegiate church, a monastery of Augustins, and 430 houses, with 3430 inhabitants. It is remarkable from having been founded in 1420, by the first Protestants, then called Hussites, and sometimes Taborites. At Tabor there are some manufactures of linens and woollens. Long. 13. 48. E. Lat. 49. 24. 23. N.

Tabriz.

TABRIZ, or Tabreez, a city of Persia, and capital of the province of Azerbijan, and for a considerable time the residence of Abbas Mirza, the heir-apparent of the Persian crown. It is seated in an immense plain at the foot of a mountain, on the banks of a small river whose waters are applied to the cultivation of the land. Tabriz was formerly a magnificent city, and, according to Chardin's account, contained, when he visited it in 1686, 15,000 houses, as many shops, 300 caravanserais, 250 mosques, magnificent domed bazaars, and 550,000 inhabitants, though this last appears rather an exaggerated estimate. At present, Morier does not consider it to be more than one tenth of its former magnitude. All the large buildings have been destroyed by earthquakes. Two of these occurred during the last century, and were particularly fatal: 100,000 inhabitants perished, having been swallowed up in the yawning abyss of the earth, with their houses; and others crushed under masses of falling ruins. Notwithstanding these calamities, a new city has arisen amid the desolation of the old; and on all sides are to be seen the ruins of houses, streets, &c., which afford some idea of the extent and magnificence of the former city. Tabriz is at this day three miles and a quarter in circumference. Morier, who visited this place in 1809, mentions that it is surrounded by walls built of sun-burnt bricks, and by towers of kiln-burnt bricks placed at irregular distances from each other. After his second visit in 1811, he mentions that, four years before, Abbas Mirza had made Tabriz his capital, and that he had repaired and beautified the walls, and otherwise improved the city. Sir R. K. Porter, by whom Tabriz was visited in 1817, also says that it had been lately re-fortified by order of the prince Abbas Mirza, who then resided in it. It is now surrounded with a thick wall, protected by towers and bastions, with the addition of a very deep dry ditch, the whole embracing a circumference of 6000 yards. The object of the prince is not so much to adorn as to strengthen the city; and, besides the fortifications, a maidan or square has been laid out by him, and surrounded with barracks for the troops which he is organizing according to European tactics. He was also building a palace for his own residence, which possessed, however, none of that pomp which distinguished the royal residences of former days. Beyond this boundary to the north and east extend the suburbs, which rise amid the ruins and broken ground which formerly composed the city. Four gates of no very imposing appearance open into the new city. They are surmounted by turrets, and ornamented with slight minarets covered with chequer-work of blue and green tiles, collected from the remains of the ancient vaulted mosques. Out of the 250 mosques mentioned by Chardin, the ruins of only three are visible. The most considerable is that of Ali Shah, erected nearly 600 years ago by Ali Koja, which still presents lofty arches and the mouldering vaulted work of splendid domes. This building, both within and without, has been cased over its whole surface with lackered tiles of porcelain, adjusted with singular taste and ingenuity into a variety of intricate and elaborate figures of green, dark, and light blue, interspersed with Arabic sentences in letters of gold; and a broad band of rich legends formed in white upon this beautifully varied ground, and interwoven with flowers in green and gold, winds round the whole extent of the building. This fine ruin is within the new fortifications of the city, where are also the remains of the ark or citadel. The latter building comprehends within its limits the remains of a mosque, which is a very finely constructed mass of brick-work, about eighty feet in height; at the top of which three small chambers have been constructed, whence the town and the surrounding country are seen as if laid out on a chart. The prince at one time intended to reside in this place; but it was sub-

Tabriz.

sequently converted into an arsenal and manufactory of arms, which was visited by Morier, and in which he saw stores of guns, artillery, and the other materiel of war, and numerous carpenters, wheelwrights, and others, with European tools, and a blacksmith's forge at work. To the southeast of the city, at the foot of a sloping hill, is a powder-mill, worked by water, and erected entirely by a Persian. It is, says Morier, by far the best structure at Tabriz, being built of brick, stone, and marble. The remains of this structure that still exist, after repeated shocks of earthquakes, prove the original solidity and excellence of the workmanship. About two miles to the south-west of the new walls of the town, but far within the remnants of the old boundaries, stand the magnificent remains of the sepulchre of Sultan Kazan. The intervening ground is marked with shapeless ruins, even stretching beyond the sepulchre to a great extent. The tomb itself has the appearance of a huge mound of mingled lime, dust, tiles, and bricks, surrounded, however, with spacious arches of stone, the remains of its former grandeur. Beyond the eastern gate of the town, the ruins of the ancient city reach for more than three miles over the valley, and on the adjoining heights which skirt the base of the hills. On one of the most commanding of these subordinate acclivities stands the vast and venerable structure of an ancient fortress, which from its position and strength must have commanded the whole valley. At what period this vast structure was first built, is entirely unknown; but the thickness of the walls, the massy towers, and the splendid materials of its interior parts, plainly show the great labour and cost at which it must have been reared. No sun-dried bricks have been employed in this building, which consists of huge masses of loose stones and mortar thrown together, and afterwards closely faced with large stones. A very large tower, looking towards the town and the valley, flanks the south-west front of the castle, which seems in a less impaired state than any of the other quarters. In the interior of these ruins are found several vaulted and spacious underground apartments, and near them the remains of a magnificent mosque. The shattered walls are filled up with heaps of tiles, dust, and furnace-made bricks, interspersed with the pieces of white transparent marble called Tabriz marble, which is dug up in immense blocks from the mountains on the banks of Lake Ooroomia. Sir R. K. Porter also marked the foundations of other considerable buildings, and the site where baths had been constructed. He ascribes the destruction of these edifices on the heights more to the devastations of war than to earthquakes, as the ruins that still remain mark out very clearly the plan and architectural dispositions of the edifice. The plain in which Tabriz is situated is bounded to the northeast, the east, and south-east, by a chain of barren mountains, conspicuous for their red and ochreous appearance. These mountains rise immediately behind Tabriz, and recede into a deep vale, which, being watered by a plentiful stream, is perhaps more highly cultivated than any tract of its size in Persia, and is remarkable for beautiful and picturesque scenery.

It is generally understood that the ancient name of Tabriz was Ganzaca; and no notice is found of it as the capital of Azerbijan until the fourth century of the Christian era. From that period, under the names of Ganzaca, Tauris, Tabriz or Tabreez, it has been esteemed the capital of the province. But it must have subsequently declined in consequence, as the houses of the city only amounted to 3000 when Heraclius took possession of it 300 years after. It was not till after the accession of the Sefi race of kings that Tabriz regained its former importance. It must have been a great city when it was visited by Chardin in 1686, who rates its population at 550,000. But in 1727 it was nearly destroyed by an earthquake, in which 70,000 people are said to have perished; and in a succeeding shock, which took place in 1787, only 40,000 remained to be engulphed; a proof that the population had in the mean time greatly declined. Longitude, according to the observations of the unfortunate traveller Brown, 47. 17. 46. E. Latitude, according to Major Monteith, 38. 4. N.

Tacitus

TACHYGRAPHY, from ταχὺς, *swift*, and γράφω, *I write*, or the art of writing short-hand. See Stenography.

TACITUS, Caius Cornelius, a celebrated Roman historian, and one of the greatest men of his time, appears to have been born about the fifty-seventh year of the Christian era. He early applied himself to the labours of the bar, in which he gained very considerable reputation. He was a man of equestrian rank, and was promoted to various offices. Having married the daughter of Agricola, the road to public honours was opened to him in the reign of Vespasian; but during the sanguinary and capricious tyranny of Domitian, he, as well as his friend Pliny, appears to have retired from the theatre of public affairs. The reign of Nerva restored these luminaries of Roman literature to the metropolis; and, in the year 97, we find Tacitus engaged to pronounce the funeral oration of the venerable Virginius Rufus, the colleague of the emperor in the consulship, and afterwards succeeding him as consul for the remainder of the year. In the year of the city 853, Pliny and Tacitus were appointed by the senate to plead the cause of the oppressed Africans against Marius Priscus, a corrupt proconsul, who was convicted before the fathers; and the patriot orators were honoured with a declaration that they had executed their trust to the entire satisfaction of the house. The time of the historian's death is not mentioned by any ancient author, but it is probable that he died in the reign of Trajan.

His works which still remain are, 1. The Life of Agricola, his father-in-law; 2. On the Manners of the Germans; 3. Five books of his History; 4. His Annals. There is also attributed to him a dialogue "De Causis corruptæ Eloquentiæ," which others have ascribed to Quintilian. The treatise on the manners of the Germans was published in 851. The exact time when Tacitus published his history is uncertain, but it was in some period of Trajan's reign, who died suddenly, a. u. c. 870, a. d. 117. The history comprises a period of twenty-seven years, from the accession of Galba, 822, to the death of Domitian, 849. The history being finished, he did not think he had completed the tablature of slavery: he reverted to the time of Tiberius; and the second work, which, however, comes first in the order of chronology, includes a period of fifty-four years, from the accession of Tiberius, 767, to the death of Nero, 821: this work is his Annals.

No author has obtained a more splendid reputation than Tacitus. It is impossible not to admire and recommend his intimate knowledge of the human heart, the spirit of liberty which he breathes, and the force and vivacity with which he perpetually expresses himself. He has been censured as obscure; and indeed nothing can be more certain than that he did not write for the common mass of men. But to those who are judges of his compositions, it is no matter of regret that his manner is his own, and peculiar. Never were description and sentiment so wonderfully and so beautifully blended; and never were the actions and characters of men delineated with so much strength and precision.

Of the works of Tacitus, the first edition was printed by V. Spira at Venice in 1468 or 1469. It is in folio, and without a date. After some intervening impressions, a more complete edition was superintended by Beroaldus, Romæ, 1515, fol. Here the earlier books of the Annals were printed for the first time. The subsequent editions are so numerous, that we can only specify a very small proportion. Tacitus was greatly indebted to the learned labours of Lipsius, who published several editions. His first was printed at Antwerp, 1574, 8vo. His annotations were gradually augmented, and underwent different revisals and modifications. The last edition which he himself superintended was that of Ant. 1600, fol. Passing over the editions "cum notis variorum," 1672 and 1685, we arrive at that of Ryckius, Lugd. Bat. 1687, 2 tom. 12mo. The second volume contains the editor's annotations. J. Gronovius had undertaken to prepare an edition with the notes of various critics; and after his death it was completed by his son Abraham, Traj. ad Rhen. 1721, 2 tom. 4to. Two editions by Ernesti were printed at Leipzig in 1752 and 1772, each in two vols. 8vo. An elegant edition was published by Brotier, Paris. 1771, 4 tom. 4to, 1776, 7 tom. 12mo. We now descend to the edition of Oberlin, Lipsiæ, 1801, 2 tom. 8vo; and to that of Ruperti, Gotting. 1804, 2 tom. 8vo.

The works of Tacitus have been translated into various languages. The earliest English version was executed by Sir Henry Savile and Richard Greenway. Dryden lent his ready aid to "The Annals and History of Cornelius Tacitus, by several hands." Lond. 1698, 3 vols. 8vo. Some of these hands are suspected to have been chiefly indebted to a French translation. Their version was followed by that of Thomas Gordon, Lond. 1728-31, 2 vols. fol. Gordon's phraseology is remarkable for its affectation; and by labouring to imitate the style of the original author, he has in some instances rendered his own scarcely intelligible. A more readable translation of Tacitus was produced by Arthur Murphy, Lond. 1793, 4 vols. 4to. The dialogue on eloquence has been well translated by Mr Melmoth; the life of Agricola, and the description of Germany, by Dr Aikin.

TACK, a rope used to confine the foremost lower corners of the courses and stay-sails in a fixed position, when the wind crosses the ship's course obliquely. The same name is also given to the rope employed to pull out the lower corner of a studding-sail or driver to the extremity of its boom. The main-sail and fore-sail of a ship are furnished with a tack on each side, which is formed of a thick rope tapering to the end, and having a knot wrought upon the largest end, by which it is firmly retained in the clue of the sail. By this means one tack is always fastened to windward, at the same time that the sheet extends the sail to the leeward.

To Tack, to change the course from one board to another, or turn the ship about from the starboard to the larboard tack, in a contrary wind. Thus a ship being close-hauled on the larboard tack, and turning her prow suddenly to windward, receives the impression of the wind on her head sails, by which she falls off upon the line of the starboard tack. Tacking is also used in a more enlarged sense, to imply that manœuvre in navigation by which a ship makes an oblique progression to the windward, in a zigzag direction. This, however, is more usually called *beating*, or *turning to windward*.

TACOULUM, a town of Hindustan, in the Carnatic, forty miles west from Madras. Long. 79. 50. E. Lat. 13. 4. N.

TACTICS, in the art of war, is the method of disposing forces to the best advantage in order of battle, and of performing the several military motions and evolutions. See War.

TADCASTER, a town in the wapentake of Barkston-Ash, in the west riding of the county of York, 185 miles from London. It stands on the river Wharfe, over which is a fine bridge, built from the ruins of its ancient castle, called by the Romans Calcaria, from the abundance of limestone found near it. It is a well-built town, with a well-attended market on Thursday. The inhabitants amounted in 1821 to 1651, and in 1831 to 1666.

TADMOR. See Palmyra.

TAFFETY, or Taffeta, a fine smooth silken stuff, remarkably glossy. There are taffeties of all colours, some plain, and others striped with gold, silver, &c., others chequered, others flowered, according to the fancy of the workmen.

TAGAL, a Dutch settlement on the north coast of Java, where there is a resident to receive the contributions of the chief. It is prettily situated on a broad river, and has a church and a small fort. Long. 108. 55. E. Lat. 6. 44. S.

TAGALAZ, one of the Fox Islands, in the North Pacific Ocean. Long. 185. 26. E. Lat. 53. 30. N.

TAGANROG, a fortified city of South Russia, in Europe, in the circle of Rostow and province of Caterinoslaw, about 1300 miles from St Petersburg. It is built on an elevated tongue of land, on the Sea of Azoph, which forms a small bay, where the small vessels can be secured. From the favourable situation for trade, it has become an emporium for the productions that are conveyed from the interior of the empire by the great rivers the Wolga, the Don, and the Donetz. It is a kind of free port, has quarantine regulations, custom-house, naval and land police, and is furnished with a regular garrison. The chief impediment to the progress of the commerce from this place is the shallowness of the water in the Sea of Azoph, which forbids large vessels from approaching to nearer than two miles from the city. In spite of this obstacle, however, more than 1400 vessels have been loaded in one year, with wheat, iron, tallow, oil, cordage, leather, sail-cloth, and hides. Though the greater part of the ships are Russian, yet many of them are Greek, Austrian, and English. The country around is highly beautiful and fertile, and the fruits of warm climates come to perfection in the summer in the open air, especially the melons and grapes. The city has been rapidly increasing in population ever since 1805, and is now said to contain 20,000 inhabitants. The late emperor Alexander died here in 1825, whilst busily occupied in projects to improve the place, and extend its prosperity. Long. 38. 34. 25. E. Lat. 47. 12. 30. N.

TAGAPOLA, a small island among the Philippines, twenty-five miles west of the island of Samar.

TAGLIACOZZI, Gasparo, a renowned surgeon, was born at Bologna in the year 1546. He studied in that university under Cardan, and took his doctor's degree at the age of twenty-four. He was appointed professor of surgery, and afterwards of anatomy; and after having acquired much reputation, he died at Bologna on the 7th of November 1599. His principal work is entitled "De Curtorum Chirurgia per Insitionem libri duo." Venet. 1597, fol. It was reprinted under the title of "Chirurgia nova, de Narium, Aurium, Labiorumque Defectu per Insitionem Cutis ex Humero, arte hactenus omnibus ignota, sarciendo." Francof. (1598), 8vo. This new title sufficiently indicates the art which he professed, of repairing noses, ears, and lips, by a species of ingrafting. The name of *Taliacotius* is well known to the readers of Hudibras.

TAGOLANDA, a small island, about twenty miles in circumference, situated off the north-eastern extremity of Celebes. It is populous, and plentifully supplied with provisions. Long. 125. 5. E. Lat. 2. 10. N.

TAGUS, or Tajo, the largest river of Spain; which, taking its rise on the confines of Aragon, runs south-west through the provinces of New Castille and Estremadura; and passing by the cities of Aranjuez, Toledo, and Alcantara, and then crossing Portugal, forms the harbour of Lisbon, at which city it is about three miles broad; and about eight or ten miles below this it falls into the Atlantic Ocean.

TAGYPEEL, a small island in the Eastern Seas, near the north-east coast of Borneo. Long. 117. 54. E. Lat. 6. 29. N.

TAHEJ, a town of Hindustan, in the province of Cutch, of which it was formerly the capital; but it has now dwindled into a small village. Long. 76. 27. E. Lat. 23. 17. N.

TAHMOR, a town of Hindustan, province of Oude. Long. 81. 10. E. Lat. 27. 41. N.

TAHNESIR, an ancient town of Hindustan, in the province of Delhi, in the Sikh territories, ninety miles north by west from the city of Delhi. Long. 76. 30. E. Lat. 30. N.

TAHNOON, a district of Northern Hindustan, tributary to the Ghoorkali rajah of Nepaul. It has an irregularly mountainous surface, and is known to be but thinly inhabited. To the south it is bounded by the British territory of Terriani, at the foot of the Himalaya Mountains.

TAHNUM, a town of Northern Hindustan, tributary to the Ghoorkali rajah of Nepaul, about twenty-five miles north-west from Gorcah. Long. 84. 10. E. Lat. 28. 41. N.

TAHOOROWAH, one of the smaller Sandwich Islands, situated about nine miles from the south-west part of Mowee. Long. 199. 30. E. Lat. 21. 40. N.

TAHRAH, a town and fortress of Hindustan, in the province of Cutch, situated about thirty miles from Luckput Bunder, on the road from that place to Mundavee, a seaport in the Gulf of Cutch.

TAHUK, or Tabuk, a town of Hedsjas, in Arabia, the first conquest made by Mahommed. It is 176 miles south-south-east from Jerusalem.

TAIF, or Tayf, a town of Arabia, in the Hedsjas, situated in a mountainous but fertile and well-cultivated district. It was visited by Burckhardt in 1814, who describes it at that time as nearly in a state of ruin, many of the buildings having been nearly destroyed by the Wahabys when they took Taif in 1802; and the town having afterwards been abandoned, every thing is hastening to decay. There were not more than four or five buildings, inhabited by the principal officers of the pacha, above the common size. There were at that time two small mosques. The tomb of El Abbas, which had a good dome over it, and was often visited by pilgrims, was entirely destroyed by the Wahabys. Taif is celebrated for its beautiful gardens, which are situated some distance from the town, are well watered by wells and rivulets descending from the mountains, and produce grapes of a very large size and delicious flavour, figs, quinces, and pomegranates, besides all the other fruits which are found in these climates. They are also renowned for the finest roses, which, like the grapes, are transported to all parts of the country. There are small pavilions in these gardens, to which the people of Taif, and formerly the great merchants of Mecca, resorted in summer. They had all their houses and establishments here, and lost considerable property when the town was plundered by the Wahabys. The indigenous inhabitants of Taif are Arabs. There are a few natives of Mecca, but the far greater part of the foreigners are Indians by origin, who still preserve the dress and manners of Indian Mussulmans. Some are merchants, but the greater part are druggists, whose trade is of great importance from the general predilection of all classes for drugs and perfumes. Taif was a commercial town before the Wahaby invasion, when it was plundered. It was resorted to by the Arabs of the country around for articles of dress, while by the mountain tribes were brought supplies of wheat and barley in caravans. It was also a considerable entrepôt for coffee, brought from the mountains of Yemen by the Bedouins on camels. When Burckhardt visited it, every thing denoted great misery. The only imports from the interior were dates; and the streets abounded with beggars, many of whom must have perished with hunger, as it cost at that time a sum equal to tenpence to procure bread enough for a man's daily subsistence. The town is supplied with water from two copious wells. It is sixty miles south-east from Mecca.

TAIL, the train of a beast, bird, or fish, which in land animals, it is said, serves to drive away flies, &c. and in birds and fishes to direct their course, and assist them in ascending or descending in the air or water. But the tail in all animals is of great use in directing their motions.

Tail, or Fee-tail, in *Law*, is a conditional estate or fee, opposed to *fee-simple.*

TAILZIE, in *Scotish Law*, the same with entail, a deed settling an estate upon a series of heirs, and generally accompanied with conditions and limitations, making a perpetuity.

TAIMBOORNY, a town of Hindustan, province of Aurungabad, now belonging to the British. Long. 75. 23. E. Lat. 18. 0. N.

TAIMUR, a cape of Asiatic Russia, in the district of Turuchansk, on the Frozen Ocean.

TAIMURSKAIA, a gulf of the Frozen Ocean, on the coast of Asiatic Russia. Long. 94. 10. to 98. 10. E. Lat. 75. to 77. N.

TAIN, a royal borough of Scotland, and the county town of Ross-shire. It is situated on the margin of the Firth of Dornoch, about a mile from the sea, in the neighbourhood of a fertile and well-cultivated country. The town is pleasant and prosperous. It is provided with an excellent academy, taught by a rector and two masters. The trade is principally confined to the demands of the town and adjoining districts. Tain unites with Cromarty, Dingwall, Dornoch, Kirkwall, and Wick, in sending a member to parliament. The population of the borough and parish in 1831 amounted to 3078, of which about 2000 belonged to the borough.

TAI-PING, a city of China, of the first rank, in Kiangnan, on the Yang-tse-kiang river, and at the junction of three of its tributaries. It is 525 miles south of Pekin. Long. 118. 14. E. Lat. 31. 38. N.

Tai-Ping, a city of China, of the first rank, in Quangsee, near the confines of the kingdom of Tonquin. It is built on a point of land which is almost surrounded by a river. Long. 106. 34. E. Lat. 22. 25. N.

TAITONG, a city of China, of the first rank, in Shansee, situated in a mountainous country, and exposed to the incursions of the Tartars. It is well fortified, and has a strong garrison. It is 155 miles west of Pekin. Long. 112. 44. E. Lat. 40. 5. N.

TAI-YUEN, a city of China, of the first rank, in Shansee. It is populous, and strongly fortified. It is 230 miles west-south-west of Pekin. Long. 111. 56. E. Lat. 37. 54. N.

TAJGAUW, a town of Hindustan, in the province of Bejapoor, fortified, in 1792, by Purseram Bhow. It is seventeen miles north by west from Merritch. Long. 75. 55. E. Lat. 16. 47. N.

TAKAKAKAN, a small island in the Eastern Seas, near the east coast of Borneo. Long. 116. 51. E. Lat. 38. N.

TALALAP, one of the Philippine Islands, where the Spaniards, in 1730, built a church, and established a religious mission; but the whole party were soon after murdered by the natives, and the church was demolished.

TALAVERA, usually distinguished by the addition to its name of *de la Reyna*, is the capital of a partido, which comprises within it almost the whole of the western side of the province of Toledo, in Spain. It is a place of great antiquity, containing many Roman monuments. When Spain was invaded by the Moors, it speedily surrendered, but was successively occupied and plundered by the contending armies as long as the Mahommedan power existed in the Peninsula. It is remarkable as the scene of the first great conflict that occurred between the British army under the command of the duke of Wellington, and the French. On the 27th and 28th July 1809, the British army, of 19,000, with a Spanish force of 40,000 indifferent troops, were repeatedly attacked in their position by a well-appointed French army of 47,000 French troops, under the command of the intrusive king Joseph Bonaparte. The conflict was severe, but the British repelled the attacks, and the enemy retreated. Though the victory was thus gained, it was indecisive, as the duke of Wellington soon afterwards retreated, and his wounded men fell into the hands of the French. The city stands on a beautiful plain watered by the Tagus. It is but indifferently built, has seven churches, one of which, that of the Hieronymites, is very fine, and no less than twelve monasteries. It contains about 5000 inhabitants, but with the suburbs and contiguous villages about 8000. The chief occupation is the fabrication of silk stockings; but there are manufactures of soap, of earthen ware, of hats, and cordage, upon a small scale. Talavera is remarkable as the birth-place of Mariana, the historian of Spain. Long. 5. 1. 5. W. Lat. 39. 59. 50. N.

TALENT signifies both a weight and a coin very common among the ancients, but very different among different nations. The common Attic talent of weight contains 60 Attic minæ, or 6000 Attic drachmæ; and weighed, according to Dr Arbuthnot, 59 lbs. 11 oz. $17\frac{1}{7}$ gr. English Troy weight. There was another Attic talent, by some said to consist of 80, by others of 100 minæ. The Egyptian talent was 80 minæ, the Antiochian also 80, the Ptolemaic of Cleopatra $86\frac{2}{3}$, that of Alexandria 96, and the Insular talent 120. In the valuation of money, the Grecian talent, according to Dr Arbuthnot, was equal to 60 minæ, or, reckoning the mina at L.3. 4s. 7d., equal to L.193. 15s. The Syrian talent, in this valuation, consisted of 15 Attic minæ, the Ptolemaic of 20, the Antiochian of 60, the Eubœan of 60, the Babylonic of 70, the Greater Attic of 80, the Tyrian of 80, the Eginæan of 100, the Rhodian of 100, and the Egyptian of 80 minæ. There is another talent much more ancient, which Dr Arbuthnot calls the *Homeric talent* of gold, which seems to have weighed six Attic drachms or three darics, a daric weighing very little more than a guinea. According to this talent, some reckon the treasure of King David, particularly that mentioned 1 Chron. xxii. 14, which, according to the common reckoning, would amount in gold talents to the value of L.547,500,000, and the silver to above L.342,000,000. As David reigned in Judæa after the siege of Troy, it is not improbable but Homer and he might use the same numeral talent of gold. Among the Romans there were two kinds of talents, the *little* and the *great* talent. The little was the common talent; and whenever they say simply *talentum*, they are to be understood of this. The little talent was sixty minæ or Roman pounds; the mina or pound being estimated at 100 drachmæ or denarii. It was also estimated at twenty-four great sesterces, which amounted to sixty pounds. The great talent exceeded the less by one third part. Budæus computes that the little talent of silver was worth L.75 sterling, and the greater L.99. 6s. 8d. sterling. The greater of gold was worth L.1125 sterling.

TALENT, as a species of money, among the Hebrews, was sometimes used for a gold coin, the same with the shekel of gold, called also *stater*, and weighing only four drachms. The Hebrews reckoned by these talents as we do by pounds, &c. Thus a million of gold, or a million of talents of gold, among them, was a million of shekels or nummi; the nummus of gold being the same weight with the shekel, viz. four drachms. But the Hebrew talent weight of silver, which they called *cicar*, was equivalent to that of 3000 shekels, or 113 lb. 10 oz. 1 dwt. $10\frac{2}{7}$ gr. English Troy weight, according to Arbuthnot's computation.

TALGARTH, a market and borough town of the county of Brecon, in South Wales. It is situated in a fertile district; and near to it is an extensive lake, well stocked with fresh-water fish. The population amounted in 1821 to 698, and in 1831 to 741.

TALI, a city of China, of the first rank, in the province of Yunan, situated on a large lake. The mountains in the vicinity produce a species of marble, which is fashioned by the inhabitants into tables and other pieces of furniture. Long. 100. E. Lat. 25. 45. N.

TALIACOTIUS. See TAGLIACOZZI.

TALIO (*lex talionis*), a species of punishment in the Mosaic law, by which an evil is returned similar to that committed against us by another; hence that expression, "Eye for eye, tooth for tooth." This law was inserted in the twelve Tables of the Romans; but it was afterwards set aside, and a power was given to the prætor to fix a sum of money for the injury inflicted.

TALISMANS, magical figures cut or engraved with superstitious observations on the characterisms and configurations of the heavens, to which some astrologers have attributed wonderful virtues, particularly that of calling down celestial influences. The talismans of Samothrace, so famous of old, were pieces of iron formed into certain images, and set in rings: these were esteemed preservatives against all kinds of evils. There were likewise talismans taken from vegetables, and others from minerals.

TALLY is a stick cut in two parts, on each of which is marked, with notches or otherwise, what is due between debtor and creditor; and this was the ancient way of keeping all accounts, one part being kept by the creditor, the other by the debtor. Hence the tallier of the exchequer, whom we now call the *teller*. But there are two kinds of tallies mentioned in our statutes to have been long used in the exchequer. The one is termed *tallies of debt*, which are in the nature of an acquittance for debts paid to the king, on the payment of which these tallies are delivered to the debtors, who carrying them to the clerk of the pipe-office, have there an acquittance in parchment for their full discharge. The other are *tallies of reward* or allowance, being made to sheriffs of counties, as a recompense for such matters as they have performed to their charge, or such money as is cast upon them in their accounts of course, but not leviable. In the exchequer there is a tally-court, where attend the two deputy-chamberlains of the exchequer and the tally-cutter; and a tally is generally the king's acquittance for money paid or lent, and has written on it words proper to express on what occasion the money is received.

TALMUD, a collection of Jewish traditions. There are two works which bear this name, the Talmud of Jerusalem, and the Talmud of Babylon. Each of these is composed of two parts; the Mishna, which is the text, and is common to both, and the Gemara or commentary. The Mishna, which comprehends all the laws, institutions, and rules of life which, beside the ancient Hebrew scripture, the Jews thought themselves bound to observe, was composed, according to the unanimous testimony of the Jews, about the close of the second century. It was the work of Rabbi Jehuda (or Juda) Hakkadosh, who was the ornament of the school at Tiberias, and is said to have occupied him forty years. The commentaries and additions which succeeding Rabbis made were collected by Rabbi Jochanan Ben Eliezer, some say in the fifth, others say in the sixth, and others in the seventh century, under the name of *Gemara*, that is, *completion*, because it completed the Talmud. A similar addition was made to the Mishna by the Babylonish doctors in the beginning of the sixth century according to Enfield, and in the seventh according to others. The Mishna is divided into six parts, of which every one which is entitled *order* is formed of treatises, every treatise is divided into chapters, and every chapter into mishnas or aphorisms. In the first part is discussed whatever relates to seeds, fruits, and trees; in the second, feasts; in the third, women, their duties, their disorders, their contracts, marriages, and divorces; the fourth treats of the damages or losses sustained by men or beasts, of things found, deposits, usuries, rents, farms, partnerships in commerce, inheritance, sales and purchases, oaths, witnesses, arrests, idolatry; and here are named those by whom the oral law was received and preserved; in the fifth part are noticed what regards sacrifices and holy things; and the sixth treats on purifications, vessels, furniture, clothes, houses, leprosy, baths, and numerous other articles. All this forms the Mishna.

The Talmud of Babylon is most valued by the Jews; and this is the book to which they refer when they speak of the Talmud in general. An abridgement of it was in the 12th century made by Maimonides, in which he rejected some of its greatest absurdities. The Gemara is stuffed with dreams and chimeras, with many ignorant and impertinent questions, and the style is very coarse. The Mishna is written in a style comparatively pure, and may be very useful in explaining passages of the New Testament where the phraseology is similar. This is indeed the only use to which Christians can apply it; but this renders it valuable. Lightfoot had judiciously availed himself of such information as he could derive from it. Some of the popes, with a barbarous zeal, and a timidity of spirit for the success of the Christian religion, which the belief of its divinity can never excuse, ordered great numbers of the Talmud to be burned. Gregory IX. burned about twenty cart-loads, and Paul IV. ordered 12,000 copies of the Talmud to be destroyed.

The last edition of the Talmud of Babylon, printed at Amsterdam, is in twelve vols. folio. The Talmud of Jerusalem is in one large folio.

TALNERE, a town of Hindustan, in the Mahratta territories, and province of Khandesh, situated on the Tuptee river, ninety-two miles west from Boorhanpoor. It was conquered by Aurungzebe, and formed part of the possessions of Holcar, and was ceded by that chief to the British. But the governor refusing to deliver it up, it was besieged and taken by the troops under Sir Thomas Hislop in 1818, who ordered him to be executed on one of the bastions, as an example to the other refractory governors. Long. 75. E. Lat. 21. 13. N.

TAMAHOO, a small island in the Eastern Seas, near the west coast of Borneo. Long. 109. 21. E. Lat. 0. 7. N.

TAMAN, an island in the Russian province of Taurida, at the entrance of the Sea of Azoph from the Black Sea. Though properly a peninsula, it is made an island by the overflowings of the river Kuban, but which at some seasons are quite dried up. The strait of Taman is a narrow and dangerous passage leading to Taganrog, having in some places no more than thirteen feet of water. This strait, sometimes called the Strait of Yenicaleh, is defended by a powerful fort. Part of the island is low, but it contains a number of small hills of volcanic origin, from one of which there was an eruption in July 1804. There are three towns on the island. Taman, or Fanagoria, on the south-east, is a place of some trade, and is defended by a fort; Kertch, on the opposite side, stands at the foot of a steep hill, and contains about 1000 inhabitants, chiefly Greek fishermen and Jews; and Yenicaleh, beyond Kertch, contains a population of 2000 persons, and has a strong citadel. It stands in long. 36. 35. E. and lat. 45. 21. 30. N.

TAMAR, a river of Van Diemen's Land, which has more the appearance of a chain of lakes than of a regularly formed river. The waters are supposed by Captain Flinders to have forced a passage by long undermining to the sea.

TAMBAH, a town of Hindustan, province of Bejapoor, seventy miles south from Poonah. Long. 73. 35. E. Lat. 17. 28. N.

TAMBEKAN, a town of Hindustan, province of Nepaul, belonging to the Ghoorkali rajah of Nepaul, celebrated for the copper mines in its vicinity. Long. 85. 30. E. Lat. 27. 25. N.

TAMBOUR, in *Architecture*, a term applied to the Corinthian and Composite capitals, as bearing some resemblance to a drum, which the French call *tambour*. Some choose to call it the *vase*, and others *campana* or the bell.

TAMBOUR is also used for a little box of timber-work, covered with a ceiling, within the porch of certain churches; both to prevent the view of persons passing by, and to keep off the wind, &c. by means of folding doors, &c.

TAMBOUR also denotes a round course of stone, several of which form the shaft of a column, not so high as a diameter.

TAMBOUR, in the arts, is a species of embroidery. The tambour is an instrument of a spherical form, upon which is stretched, by means of a string and buckle, or other suitable appendage, a piece of linen or thin silken stuff; which is wrought with a needle of a particular form, and by means of silken or gold and silver threads, into leaves, flowers, or other figures.

TAMBOUR DE BASQUE, a well-known kind of small drum, commonly called a *tambourine*. It is much used among the Biscayans, and consists of one piece of parchment stretched over the top of a broad hoop, which is furnished with little bells. It is sounded by sliding the fingers along the parchment, or by striking it with the back of the hand, or with the fist or the elbow.

TAMBOURIN, a drum much used in Provence. Its case is much longer and somewhat narrower than that of the common drum. It is beaten with a drumstick, while the performer at the same time plays with his left hand upon a small flute, called *galoubet*. See PIPE.

TAMBURO (*Ital.*), the common military drum.

TAMBURONE, or CASSA GRANDE, or CASSA (*Ital.*), the military bass-drum. See MUSIC.

TAMBOW, a government of Russia, one of the East Sea provinces, extending in east longitude from 38° 31′ to 43° 20′, and in north latitude from 51° 8′ to 55° 9′, being 26,072 square miles. It is a level district in the northern part, sandy and swampy; but in the south it is of moderate fertility. It is well watered, some of its many streams running to the Wolga and others to the Don. The climate is healthy, but the winters are severely cold. The corn is more than sufficient for the consumption of the inhabitants, and a large quantity is distilled. The crown forests cover a large proportion of the district, and create a large export of timber and fuel. Many herds of cattle yield both hides and tallow, and the former are converted into leather for exportation. The growth of flax is extensive, and the manufactory of linens from it flourishing. There are also some manufactures of cloth, and many of iron, and some of glass ware. The trade is almost exclusively internal, the province having no communication by water with the sea. The population, by the latest accounts, is 1,422,000 persons.

TAMBOW, a city of Russia, the capital of the province of that name, 804 miles from St Petersburg. It is an ancient place, but has been much modernized of late years. It contains six wooden and seven stone churches, about 1600 houses, mostly of wood, and 15,000 inhabitants, who subsist by making linen goods and cordage, and in a greater degree by agriculture. Long. 41. 40. E. Lat. 52. 43. 44. N.

TAMERLANE, or TIMUR BEK, a celebrated prince and conqueror, was born in 1335, in the village of Kesch, belonging to the ancient Sogdiana. His origin is obscurely known, some writers describing him as of royal blood, others as the son of a shepherd. It is however evident that he chiefly owed his elevation to his talents and bravery. At the age of twenty-five he attained the highest dignities, with surprising courage, and an ambition astonishing to all the world. Endeavouring to perfect the great talents which he had received from nature, he spent nine years in different countries, where his strong sense and elevated genius appeared in councils and assemblies, while his intrepidity and valour, whether in personal combats or pitched battles, drew upon him the admiration of all mankind. He made himself master of the three empires of Jagatay Khan, Tushi Khan, and Hulaku Khan; so that his power, riches, and magnificence, were immense. Of his grandeur vast monuments remain in the cities, towns, castles, and walls, which he built; in the rivers and canals which he dug, as well as the bridges, gardens, palaces, hospitals, mosques, and monasteries, which he erected in divers parts of Asia, in so great a number, that a king might be accounted very powerful and magnificent who should have employed thirty-six years only in building the great edifices which Timur caused to be founded. He undertook the conquest of India, and having obtained possession of Delhi, he became master of the immense treasures of the Mogul empire. He afterwards invaded Syria, and took Damascus; and Bagdad having attempted to throw off his yoke, he put many thousands of the inhabitants to the sword, and delivered the city to the rapacity of his soldiers. In Bajazet, emperor of the Turks, he found a formidable antagonist. In 1402 they engaged on the plains of Ancyra; and in a battle which lasted for three days, the emperor was defeated and taken prisoner. According to the common account, the victor confined him in an iron cage. Tamerlane died on the 1st of April 1405, in the seventieth year of his age. When he found death approaching, he sent for his principal officers, declared his grandson his heir, and made them swear to execute his will. Having recommended brotherly love and concord to the princes his children, he ordered one of the doctors to read the Koran at his bed head, and often repeat the unity of God. At night he several times made profession of his belief, "that there is no other God than God," and then expired.

Timur, according to the historian Arabshâh, was in his person very corpulent and tall. He had a large head, with an ample forehead. His countenance was agreeable, and his complexion fair. He wore a long beard, was very strong and well limbed; had broad shoulders, thick fingers, and long legs. His constitution was amazingly vigorous; but he was maimed in one hand, and lame of the right side. His eyes appeared full of fire; his voice was loud and piercing; he feared nothing; and when far advanced in years, his understanding was sound and perfect, his body vigorous and robust, his mind constant and unshaken like a rock. He was surprisingly happy in his conjectures; vigilant, active, and unshaken in his resolutions. He took great delight in reading history, and was well versed in the state of countries, provinces, and cities. He was penetrating, subtle, close, and dissembling; just by inclination, liberal from disposition; but ambition had in a great measure extinguished his humanity; war had familiarized him to blood; and his religious zeal had inspired him with the most cruel, implacable, and pernicious fanaticism.

TAMTAM, or GONG. See MUSIC.

TAMWORTH, an ancient borough, situated partly in Warwickshire and partly in Staffordshire, 117 miles from London. The situation is at the confluence of the rivers Tame and Anker. The church is an ancient but irregular building, with some fine monuments. The ancient castle formerly belonged to the earls of Leicester. Near to it is Drayton Park, the seat of Sir Robert Peel. In Tamworth there are some cloth manufactures. It is a borough, governed by four aldermen and twelve councillors, and returns two members to parliament. There is a good market on Thursday. The inhabitants amounted in 1831 to 7182.

TAN, the bark of trees after it has been ground and used by the tanner. The smallest sort is generally made up in little square cakes called *turf*, and sold for firing. The coarser sort is sometimes dried in the sun, and used by bakers for heating their ovens, &c.; but its chief use is for making hot-beds to raise pine-apples and other plants. William III. introduced the use of it from Holland, for the purpose of raising orange trees; after which it was discontinued for many years: but about 1719, when *ananas* were first brought into England, it came into general use, and has ever since been in great estimation with gardeners for all the purposes of forcing, &c. on account of its strong and lasting fermentation. The smaller the tan the quicker it heats; but the larger sort acquires heat more gradually, and retains it longer. The skilful gardener therefore uses the one or the other, or a mixture of both, according to the time and purpose for which it is wanted. It is not till some time after the tan comes out of the tanner's pit that it begins to heat, and therefore it is not fit for immediate use; but having lain a week or two, it enters into a state of fermentation, and if put into hot-beds properly prepared, will retain a moderate heat for three or four months. When it becomes useless for the hot-house, it is said to be an excellent manure for some kinds of land.

The word *tan* is sometimes, though improperly, used for the *bark* itself, which is the chief ingredient in the tanning of leather. Oak bark, on account of its great astringency and gummy-resinous properties, is preferred to all other substances for the purpose of tanning, as it not only preserves the leather from rotting, but also, by condensing the pores, renders it impervious to water.

TANAH, a town of Hindustan, province of Gujerat, forty-one miles east by north from the city of Surat. Long. 73. 41. E. Lat. 21. 21. N.

TANAGA, one of the Fox Islands, in the North Pacific Ocean, about forty miles in circumference. Long. 182. 14. E. Lat. 53. 20. N.

TANAKEKE, a small island, about twelve miles in circumference, surrounded by a cluster of smaller ones. Many of the smaller islands of this group are uninhabited, and the others are peopled by the Buggesses. It is situated off the south-west extremity of Celebes. Long. 19. 10. E. Lat. 5. 30. S.

TANDAH, a town of Hindustan, in the province of Bengal, adjacent to the ruins of the ancient city of Gour. Long. 88. 15. E. Lat. 24. 49. N.

TANETE, a town and small principality in the island of Celebes, situated half way between Fort Rotterdam and the bay of Sorian. Long. 119. 35. E. Lat. 4. 14. S.

TANGERANG, a village of the island of Java, about fifteen miles west from Batavia. A large weekly bazaar is held here, to which the produce of the adjacent country is brought, and thence carried to Batavia. There is also a river of the same name, which falls into the ocean about twenty miles west of Bantam.

TANGIER, a port-town of Africa, in the kingdom of Fez, and empire of Morocco, situated at the entrance of the Straits of Gibraltar, in Long. 5. 50. W. Lat. 38. 49. N. In 1662, this place belonged to the Portuguese, and was given to King Charles II. upon his marriage with the Infanta of Portugal; but growing weary of the charge of keeping it, he caused it to be blown up and destroyed in 1684; and ever since that time it has been only a poor fishing town. It was anciently called *Tingis*, and gave name to the province of Mauritania Tingitana.

TANJORE, an extensive, populous, and well-cultivated district of the south of India, in the Carnatic, situated in the Bay of Bengal, between the 10th and 12th degrees of north latitude, and intersected by the river Cauvery. It is bounded on the north by the Cauvery river, on the south and east by the Indian Ocean, and on the west by Trichinopoly and the Polygars' territory. It is ninety-five miles in length by fifty in breadth. The inhabitants of this district are remarkably industrious and expert in husbandry, and they have erected extensive works for the irrigation of the country. The most prodigious mounds have been raised at Costady, to prevent the waters of the Cauvery from rejoining those of the Coleroon, after they have been separated near Trichinopoly; and by numerous canals they are diverted, by means of embankments and reservoirs, into every field, and fertilize a tract of country from Devicotta to Point Calymere, which without water would have remained a barren sand. The principal exports from this country to Madras are indigo, cocoa-nuts, rice, grain, paddy, lamp-oil, with some piece goods; also betel-nut, tin, pepper, tortoise-shell, benjamin, arrack, &c. The imports from Madras are small in quantity and value, and chiefly consist of articles for the European troops and residents. The seaports of chief resort are Tranquebar, Nagore, Negapatam, Carical, and Devicotta. This territory never having been actually occupied by the Mahommedans, the Hindu religion in all its original forms and ancient splendour, the ancient places of worship, with their vast endowments, remain untouched. The Brahmins are the chief proprietors of the land, and perform almost every office of husbandry except holding the plough. They are all well affected to the British government, and grateful for the protection which they receive, and also for an allowance granted by government of 45,000 pagodas for the support of the poorer temples.

It was in the province of Tanjore that the British were first engaged in warfare with the native troops, and they did not succeed in their object, which was to restore the deposed rajah of Tanjore, who had applied for assistance to the governor of Fort St David. In 1799 the territory of Tanjore was subjected to the British authority, a large pension being reserved for the maintenance of the rajah, besides one fifth of the surplus revenues after payment of the civil and military expenses; and, as a particular favour, he retains the possession of the two forts of Tanjore, which he keeps in excellent repair, and which are garrisoned with 1500 troops. The province now forms one of the districts under the Madras presidency.

Tanjore, a celebrated town and fortress, and capital of the above-mentioned district. The city comprehends two fortresses, which are given up to the rajah; but on the exigency of a war, the British have a right by treaty to reoccupy them. The small fort is a mile in circumference, very strong and in good repair. It has lofty walls, and on the corners of the ramparts are cavaliers. There is also a ditch, broad and deep, cut out of the solid rock, with a well-formed glacis. The small is joined to the large fort, where the rajah resides, which is fortified in a similar manner, and, beside the palace, contains other public buildings. The smaller fort contains the celebrated pagoda, the chief building of which is one of the finest specimens of the pyramidical temple in Hindustan. Within is a bull carved from a block of black granite, an excellent specimen of Hindu sculpture. It also contains a college, formerly a celebrated place of Hindu learning. The fortress, which may be considered as the citadel, is extremely strong, and successfully resisted the arms of both the French and the British, but was taken by the latter in the year 1773. Long. 79. 11. E. Lat. 10. 42. N.

TANK, in the language of Hindustan, a place enclosed for receiving and retaining rain-water. During the periodical rains the tanks are filled, and thus in the dry season furnish water for the rice-fields and cattle. Some of them are of great extent, measuring 300 or 400 feet on the side. They are of a quadrangular form, and lined with granite, descending in regular steps from the margin to the bottom.

TANKSAL, a town of Hindustan, in the Sikh territories, province of Delhi, 150 miles north from Delhi. Long. 76. 53. E. Lat. 30. 51. N.

TANNA, a town and fortress of Hindustan, province of Aurungabad and district of Bombay, situated on the east side of the island of Salsette. The fort, which is very strong, commands the passage between the island and the main land, which is about 200 yards broad. The fort is usually garrisoned by a battalion of sepoys, and a company of European artillery from Bombay. The town is straggling, but not large, and has several Portuguese churches, with a number of Christian inhabitants. It was taken from the Mahrattas in 1773, after an obstinate resistance. Long. 73. 5. E. Lat. 19. 10. N.

Tanna, an island in the South Pacific Ocean, one of those called the New Hebrides, discovered by Captain Cook in the year 1774, about twenty-two miles in length and ten in breadth. Long. 169. 44. E. Lat. 19. 32. S.

Tanna Balloo, a small island in the Eastern Seas, near the east coast of Borneo. Long. 118. 21. E. Lat. 4. 52. N.

TANNER, Thomas, an eminent antiquary, was born in 1674. His father, Thomas Tanner, was vicar of Market Lavington in Wiltshire. The son was sent to Queen's College, Oxford, in 1689; took the degree of A.B. in 1693, and that of A.M. in 1696; and was elected a fellow of All Souls College in 1697. He became prebendary of Ely in 1713, archdeacon of Norfolk in 1701, and canon of Christ Church in 1724. He was consecrated bishop of St Asaph on the 23d of January 1732; and died at Christ Church on the 14th of December 1735. He was thrice married. Dr Tanner was a very industrious antiquary, and left an immense collection of papers, which are preserved in the Bodleian Library. He had a considerable share in the second edition of Wood's Athenæ Oxonienses. He published a work entitled "Notitia Monastica; or, a short History of Religious Houses in England and Wales." Lond. 1695, 8vo. After the author's death, an enlarged edition was published by his brother the Rev. John Tanner, Lond. 1744, fol. And an improved edition was published by Mr Nasmith in 1787. His principal work, with which he had been more or less occupied for the space of forty years, bears the title of "Bibliotheca Britannico-Hibernica; sive, de Scriptoribus qui in Anglia, Scotia, et Hibernia, ad sæculi XVII. initium floruerunt." Lond. 1748, fol. The preface was written by Dr Wilkins, who did not live to see the completion of the work.

TANNING, the art of converting hides and skins into leather. This art has been practised for many centuries in Britain; but some improvements have been recently made on it, suggested by the discoveries of modern chemistry. These we shall briefly notice, after having described the method generally practised.

The leather tanned in England is generally divided by the manufacturer into three kinds; butts or backs, hides, and skins. Butts are made from the stoutest and heaviest ox-hides. The butt is formed by cutting off the skin of the head for glue-pieces, the neck, which is tanned as a shoulder, and the shanks and a strip of the belly on each side, which, with the shoulder, are tanned in the poor tanning fluids left by the remaining central part or butt of the hide. Hides, or crop-hides, are made from cow-hides, or the lighter ox-hides, whole, and employed for ordinary soles, whereas butts are used for boots and the stoutest shoes. The term skins is applied to all the other kinds of leather, comprehending that made from the skins of calves, seals, dogs, kids, &c.[1]

The first operation to which they are subjected is depilation, which removes not only the hair, but also the scarf-skin. This is effected variously in different countries. In England the most common plan is to throw the hide or skin into a strong solution of slaked lime, with lime in excess. Here, in a few days, more or less according to the proportion of lime present, the hair is easily detached, the hair-sheath having been dissolved, and at the same time the scarf-skin with the hair is scraped off upon a sloping rest, with a species of knife with two handles. The lime has also combined with the fat of the hide to form a calcareous soap, to dissolve which, and the excess of lime, it is well washed, sometimes in a running stream. The hide is fleshed, or deprived of the loose or extraneous flesh or cellular tissue; and if butts are to be made, the head, shoulder, and bellies are cut off. The central part or butt weighs about two thirds of the whole leather. The hair was formerly taken off by making a sour liquor from fermented vegetable matter, in which the hide lay for several days; they were also smoked in a damp state for the same purpose; but both those methods are now abandoned. They are still sometimes sweated, that is, they are laid in heaps, kept wet and warm: but in America the sweating is performed cold; the hides are hung up wet in a damp underground cellar, and are kept wet for ten days or a fortnight. In either of the three last processes, incipient putrefaction takes place sooner or later, when the hair and scarf-skin are easily removed; but the fatty matter remains, and in some cases prevents the hide from taking the tan. The tanning either follows at once, or is preceded by what is called abating or grainering. For this process, a quantity of pigeon's dung is steeped in water. In this mixture the hides are steeped for a week or ten days, with occasional removals and strikings. The excess of lime is removed by the lithic acid of the dung; and the ammonia generated by the putrefaction of the mixture tends to form an ammoniacal soap with any remaining fat of the hide: but as the gelatine of the hide exists in two states; one, the principal, hard, or fibrous portion,—and the other (which is more soluble) contained between the fibres, and more affected by agents and putrefaction; this softer portion is removed by grainering, and the leather, when tanned, is light and porous, and more readily permeable to water.

---

[1] Hides are imported in large quantities, and sold as wet salted, dry salted, or dry hides. The two latter require some preparation in order to soften them; they are thrown into water, and frequently taken out and brushed and stretched, by being placed upon a cylindrical table and smoothed with a blunt knife by degrees: their horny character is lost, and they become pliant and soft. In some places dry hides, after depiling, are softened by working them with water in a pair of stocks like those of the fuller. A dry hide of 30 lbs. should produce as much leather as a wet salted one of 60.

Some tanners are anxious that their leather should look thick when completed. To "raise" the hide, they use a solution of sulphuric acid, containing $\frac{1}{500}$th part of acid: in this the hides remain ten or twelve hours, when they are found to be thickened, or to have substance; but as nothing is added to the gelatine by the process, it is only the appearance which is altered, and no difference of thickness is found in the leather after it has been under the shoemaker's hammer.

The hide or skin thus prepared is ready for tanning. Formerly in England, and at present on the continent, it is done by stratification. A bed of bark is made upon the bottom of the pit; upon this is laid the hide, then bark, then a hide, until the pit is full; water is sometimes pumped in, and the pit left for some months; it is then emptied, and the same hides returned with fresh bark and water for a few months longer: this is repeated again and again, until the tanning is completed; the time varying from one to four years for heavy leather.

About the end of the eighteenth century, Seguin professed to give a theory of tanning. He showed that astringent solutions contained gallic acid, which precipitated sulphate of iron black, but did not precipitate gelatine; whereas the tannin present threw down gelatine as well as sulphate of iron; and from this he deduced that leather was a compound of gelatine and tannin. Upon this he founded a new process. He recommended solutions of tannin, made by pumping water successively upon the vegetable used, contained in latches or spenders, until it arrived at as great a degree of strength as the series of spenders permitted. In this way he was continually throwing away some bark as expended, and replacing it with fresh, which was next to be the strongest tap.

This is the plan now generally followed in England; but in practice it is varied, some using ground bark only, others terra japonica, valonia, or divi-divi, or mixtures of two or more; some using steam to facilitate the solution, others steaming only the backward latches; and some using only cold water. In some yards clean water only is used to extract the soluble matter, while in others the ooze, exhausted as much as it can be by hides, is made to perform the office instead of water. Every tanner has also his own particular strength of liquor to work at, the strongest being about sixty degrees, while others do not go beyond ten degrees. It is these variations which cause so great a variety among the samples of leather in the market.[1]

This improvement of Seguin proved a most important one; and although not equal in practice to his original ideas, yet it has shortened the period to about half of that previously occupied. The principal difficulty experienced in its use occurs in the estimation of the real quantity of tanning material actually in solution. He proposed the use of a solution of gelatine, isinglass, or glue, which was to be dropped into the fluid as a test of the presence of the tannin. In the hands of an experienced chemist this is a tolerable means of arriving at the quantity; but it proved too difficult for the tanner of the day. He therefore judges by the astringent taste of the solution, and its darkness of colour; or depends upon its strength from a certain weight of bark, &c. which may have been used.

Upon the principle that substances dissolved in water increase its density, an instrument is used which is a variety of gravimeter—a floating bulb with a stem, graduated into certain fractional parts of the bulk of fluid displaced by it. This is generally called a barkometer; and although it only indicates and measures differences of gravity, and consequently does not *necessarily* indicate whether it is tan, or gum, or sugar, in solution, yet in tanning solutions it affords a tolerable approximation to the relative strengths of solutions from the same substances. Each degree upon the stem is equal to $\frac{1}{1000}$th part of the weight of water. Thus, 1° shows the specific gravity of the fluid to be 1·001, and 60° are equal to specific gravity 1·060, water being 1·000. But this instrument is but of little use in oozes which have been long upon hides, as tannin is converted by long exposure into gallic acid, acetic acid, and carbonic acid gas: these act upon the soluble or interstitial gelatine, and by dissolving it in the poor ooze, give the fluid an apparent and not a real value by the instrument. Thus, if a spent liquor of 5° or 6° by the instrument be tasted, or tested, it will be found to have no astringent taste; it will give no precipitate to gelatine while at the bottom, and in suspension it will contain gelatine, gallate of lime, and acetate of lime. Again, temperature alters the apparent strength; and if an ooze indicating 30° be heated gradually, it will be found to appear weaker as the temperature rises, until at 190° Fahrenheit it will settle at 0, or no strength at all.[2]

---

[1] Some tanners, instead of laying their hides flat in the ooze, suspend them vertically. They are penetrated more quickly, but require frequent moving to prevent the fold from being an objection to their future sale; and a pit will not hold so many suspended as it will of laid hides. Skins, particularly light ones, are sometimes tanned by sewing them up as bags, filling them with fluid, and then throwing them into pits; but although they thus tan quickly, they require a great deal of room.

[2] When tannin in solution is exposed to the air for a short time, the following changes take place: every two atoms of tannin absorb six atoms of oxygen from the air, and are thus converted into three atoms of gallic acid, three atoms of acetic acid, and three atoms of carbonic acid gas. The gas flies off in part; the other two acids remain, and give the acid taste and properties to the tanners' poor liquors:

$$\begin{array}{lccc}
\text{Two atoms of tannin..........} & C^{36} & H^{18} & O^{24} \\
\text{Take from air..........} & & & O^{6} \\
\hline
 & C^{36} & H^{18} & O^{30}
\end{array}$$

The hide or butt, to tan it, is brought from the beam-yard and introduced into a poor and milky liquor, in which it is "handled" for four or five days; that is, it is lifted by hooks from the pit, laid with others in a heap on the side, where it is allowed to drain, and is then returned into the pit. The lime is intended to be taken out here by the gallic and acetic acids of the poor ooze, as it is found in practice that the presence of lime tends to darken the colour of the future leather: this effect is produced by *all alkalies and alkaline earths.* The hide is next successively handled into, and out of, all the handlers, increasing in strength; and in this way at length, having after some months got to the strongest handler, it is found to be stained through, though not tanned, when it is removed to the troughs which contain still stronger liquors: these it successively passes through, being handled at longer intervals. Upon arriving at the end of this series, it is laid away in a pit of very strong liquor to colour, having had powdered bark of valonia sprinkled over its surface. When the process is deemed complete it is taken out, and it will be found converted into leather; and a portion of its gelatine which has been dissolved from its interior is, by combination with a portion of tannin from the strong solution, deposited upon its surfaces, where it is found in the form of a yellow deposit, technically known as "bloom," or "pitching," which disguises the under colour of the leather, just as if it were covered with yellow paint. This, prejudice says, must be on its surface or it is not saleable; but it is so much quality and weight lost to the consumer, as he pays for it on the outside of his leather, to be scraped off by the shoemaker in the operation of buffing; and the leather is so much the worse, as, if it had remained incorporated with the leather, this would not have been so porous, or so permeable to water. The health of the wearer of the shoe is perhaps sacrificed by wet feet occasioned by the desire of his shoemaker to see a yellow paste on his leather, which in work he scrapes off with a piece of glass.

The theory of the formation of the bloom is this. As soon as ooze has penetrated into a hide, it loses its tanning material, but by capillary attraction is detained; this exhausted ooze acts by maceration on the finer and more soluble interstitial gelatine, and dissolves it. In handling, about one twelfth of this flows out; the remaining eleven twelfths accompany the hide into the next stronger solution, of which only one twelfth is absorbed directly, and a small portion is slowly exchanged by endosmosis and exosmosis. The small portion of strong solution which passes into the pores of the hide contributes to tan the hard fibrous portions not dissolved; and the small portion of weak solution passing out of the hide by exosmosis, gives up its dissolved gelatine to the tan of the stronger solution outside, to form tannate of gelatine, which partly adheres to the surface as bloom, and partly falls to the bottom of the pit as pitching. It is to be hoped that such an exposition will tend to explode this absurdity, and lead to the adoption of a system of tanning in which the exhausted ooze shall be so quickly removed by pressure as not to allow it to dissolve the finer and better portions of the skin. Some years since Mr Spilsbury endeavoured to introduce a new principle in tanning, by which some part of this action should be prevented, by bringing strong ooze at once into contact with the inside of the hide. He obtained a patent for a plan of tanning by infiltration. He fastened two hides in clamps, so that the frame represented four sides of a box, and the two hides two sides. By filling this box with strong tanning ooze, and forcing it through the pores by the pressure of a column of the fluid, he expected to tan them promptly and well; but he was not aware that a large excess of tannin dissolves gelatine, and thus tannate of gelatine was found on the outside of his box in long masses of slime, while the leather had lost as much in weight, was porous, and was tanned very much more in the thin than the thicker parts, as the fluid always passed through the easiest channel. Many other inconveniences attending the process caused it soon to be abandoned; but the erroneous principle upon which it was founded not having been made public, three other patentees have followed in the same track. Mr Drake of Bedminster sewed hides together so as to form a bag, which he placed inside a hollow frame-work of wood to support the bag, and then filled it with ooze. Mr William Cox of Bedminster sewed up a hide as it was on the animal's back, laced a canvass support round, and then filled it with ooze; and Mr Chaplin sewed his hide into a bag, filled it with ooze, but laid it in a reclining position, turning it periodically. Three if not the whole of these plans are now abandoned by the patentees themselves.

Seguin's process of tanning by solutions, although a great improvement upon the old method, is still tedious, and most expensive. Where warm oozes are used it lasts six or seven months for sole-leather; where cold oozes are in use, it extends to twelve months, consequently the tanner can turn his money only once a year: he must have capital enough to pay for twelve months' hides, bark, &c., labour and contingent expenses, besides keeping a stock of leather; and when his capital has been turned at the end of twelve or more months, it must pay him in one single profit, the interest, &c. of twelve months. This has confined the trade to a few wealthy individuals, who look upon tanning as an investment for capital, rather than as a business which might be improved by science; and being in comfortable circumstances, they are not driven to personal exertion and close application, which would be required of less wealthy tradesmen. It is from these circumstances that tanning has been more stationary than any other manufacture, and the few improvements which have been made in it have not been made by tanners. A more recent patent appears at present to occupy considerable attention. It is founded upon the principles put into action in washing a sponge. The old tanner takes his sponge (the hide) full, or nearly so, out of one ooze, and inserts it nearly full into the next. The patentees of the roller and belt system squeeze, by a simple and self-feeding press, their hide, before they drop it into the fresh ooze; and this very simple modification bids fair to revolutionize the trade, and it is already very extensively introduced into this and foreign countries.

Messrs Herapath and Cox of Bristol, the patentees, say, that to tan 100 butts per week, they erect in a tanyard, at present capable of tanning fifty per week, six or eight large pairs of rollers, one pair over each pit. The lower roller is thirty inches in diameter, covered with horse-hair cloth; the top one eighteen inches, with levers for weights, covered with woollen cloth, each covering nailed on. For each pair of rollers there are from fifty to 100 hides connected together, head to head and tail to tail, each by about four strings. Now the first butt or hide is inserted between the rollers loaded to the proper pressure; and upon turning the bottom

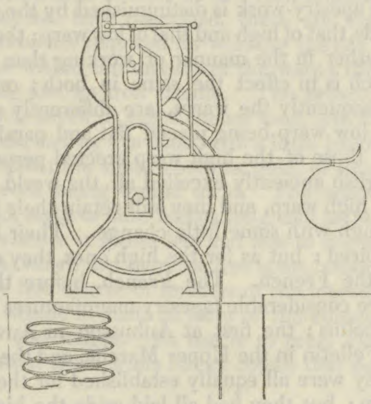
Three gallic acid	C^{21}	H^{9}	O^{15}
Three acetic acid	C^{12}	H^{9}	O^{9}
Three carbonic acid	C^{3}		O^{6}
	C^{36}	H^{18}	O^{30}

So that it may be said that the air takes three atoms of carbon from two atoms of tannin, and leaves the remainder in the state of gallic and acetic acids. The letters C, H, and O, in the table, mean carbon, hydrogen, and oxygen.

roller (which requires very little force, as it is a slow motion), all parts of the butt are pressed as pulled through by the rollers; the next comes in order by the assistance of the strings; and so on, until the whole of the hides in the belt have been pressed, and deposited in the fluid on the other side of the pit. By a detent the motion is now reversed, when the belt is again pressed, and returned to its original position for a fresh supply of ooze. This simple plan brings strong ooze so frequently into the interstices of the hide, that the centre of a stout butt is not only stained through, but tanned, in between one and two months; calf-skins and kips are tanned in from twenty to thirty days; and the liquors are so rapidly exhausted, that they are reduced from 45° to nothing in thirty-six days, losing at first more than 2° per day; and the shortness of this exposure to the air prevents much of the tannin from being decomposed. At Nailsea, near Bristol, 100 butts per week are tanned, with six latches, six rolling pits, twenty-four handlers for the offal, and six layers; one horse power drives the rollers, and two boys manage them. The following are given to us as the results produced in the first yard which was put entirely on the patent plan, as compared with those of the same yard on the old plan. Double the work is done, and half the capital drawn out as useless. The saving on bark, labour, and general cost of manufacture, is $1\frac{1}{8}$d. per lb. The increase in the weight of butt leather is as 34 lb. to 28 lb.; $46\frac{1}{2}$ lb. of leather being produced from a 60 lb. wet salted hide. The butts are sent to market within four months from the time the hides are delivered to the yard. The profits from quick return, great weight, and small expense, are eight times as great as on the old plan, at similar prices of hides, bark, and leather. The leather is more elastic and more impervious to wet than any other that is made.



Oak bark was formerly the only substance used in tanning; but large quantities of valonia and terra japonica are now imported for the purpose; and recently a bean pod called divi-divi has excited attention. These substances have lessened the demand for oak bark, of course lessening the price, and rendering it not so needful to cut down oak for the sake of the bark. Valonia gives to leather great solidity and weight: the colour inclines to gray, while there is a considerable quantity of bloom on its surface. The colour of terra japonica leather is dark fawn, inclining to red; it is light, spongy, and very pervious to water: while that from oak bark is well known to be a light fawn, and does not resist water so well as that from valonia. These differences arise from the varying proportions of tannin, extractive colouring matter, and vegetable acids present; and as the tanner has the prejudices of his buyers to consult, he selects that material, or mixture of materials, which best suits his locality. There are other vegetable productions which contain tannin. Sir H. Davy estimates 1 lb. of catechu (terra japonica) as equal to $2\frac{1}{4}$ of galls, 3 of sumach (which also contains oxalic acid), $7\frac{1}{2}$ of the bark of the Leicester willow, $8\frac{1}{2}$ of oak bark, 11 of the bark of the Spanish chestnut, 18 of elm bark, and 21 of common willow bark. Few barks are entirely free from it; and recently patents have been taken out for using the bramble and the hop-bine in tanning; but they possess the serious inconvenience of requiring very much latch-room.[1]

In trying the quantity of tannin by Seguin's process, that is, by precipitating it with solution of gelatine, 480 grains of the bark in coarse powder should be acted on by half a pint of boiling water. The mixture should be frequently stirred, and suffered to stand twenty-four hours; the fluid should then be strained through a linen cloth, and mixed with an equal quantity of solution of gelatine, made by dissolving glue, jelly, or isinglass, in hot water, in the proportion of a dram of glue or isinglass, or six table-spoonfuls of jelly, to a pint of water. The precipitate should be collected by passing the mixture of the solution and infusion through folds of blotting paper, and the paper exposed to the air till its contents are quite dry. Every 100 grains of precipitate contains 40 grains of tannin nearly.

When butts or crops are tanned, they are taken out and hung up to dry; but once or twice during drying they are placed upon a bench which is cylindrical and inclined to the horizon. Upon this they are struck or smoothed with a square bar, the surface being occasionally wetted. When the drying is sufficiently advanced, they are rolled with a brass roller about nine inches wide, loaded with from 15 cwt. to 30 cwt. This operation is called finishing.

TANORE, a decayed town on the sea-coast of Malabar. It is thirty miles south by east from Calicut. Long. 75. 55. E. Lat. 10. 55. N.

TANTALUS, in fabulous history, king of Phrygia and Paphlagonia, was the son of Jupiter and the nymph Plota. He one day entertained the gods at his table, when, to prove their divinity, he served up his son Pelops cut in pieces. All the deities, except Ceres, perceived his cruelty and impiety, and would not touch his provisions. That goddess, whose thoughts were solely employed about her daughter Proserpine, inadvertently ate a part of his left shoulder. Pelops, however, was restored to life, and an ivory shoulder given him in the room of that which had been eaten; while Tantalus was thrown into Tartarus, where he was punished with perpetual hunger and thirst. He was chained in a lake, the water of which reached up to his chin, but retired when he attempted to drink. The branch of a tree loaded with fruit hung down even to his lips, but on his attempting to pluck the fruit the branch sprung upwards.

TAOO, one of the Friendly Islands, in the South Pacific Ocean, about twenty-four miles in circumference.

TAORMINA, a town in Sicily, situated on a high rock, and eighty-eight miles south of Messina. A colony from the isle of Naxos settled at the foot of Ætna, at no great distance from the shore, and at about a league or a league and a half from the present situation of Taormina. Dionysius the tyrant attacked this colony, and either took or set fire to their city. The inhabitants retired to the rocks of Mount Taurus, among which they found a tract of ground sufficiently level and secure, and of sufficient ex-

tent. Here therefore they built a city, which, after the mountain, they named Tauromenium. It was at length raised to a very flourishing state by trade, and became celebrated as a seat of the arts, the remains of which show that the fine arts must there have been once successfully cultivated. Among other relics are still to be seen a spacious theatre, a tomb, and a long natural grotto, which appears to have been anciently adorned within with artificial ornaments. After the inhabitants of Taormina embraced Christianity, they still continued to visit this grotto with devout veneration. Instead of the pagan divinities to whom it had before been sacred, they substituted a saint, the venerable St Leonard. But St Leonard did not long draw crowds to this grotto; and the Christians have either defaced its pagan decorations, or suffered them to fall into decay by the injuries of time. It is now black and smoky; and it is with difficulty that any remains of the Greek paintings with which it was once ornamented can be distinguished.

TAOUKA, one of the Society Islands, in the South Pacific Ocean. Long. 145. 9. W. Lat. 14. 30. S.

TAPANOOLY, a small British settlement in Sumatra, situated on a small island at the bottom of the bay of Tapanooly on the north-west shore. It was taken by a French squadron in 1760, and also in 1809, when the inhabitants were plundered. Long. 98. 50. E. Lat. 1. 40. N.

TAPER denotes a kind of tall wax-candle, placed in a candlestick, and burnt at funeral processions, and in other church solemnities.

Paschal Taper, among the Romanists, is a large taper, to which the deacon applies five pieces of frankincense, in holes made for the purpose in the form of a cross; and which he lights with new fire in the ceremony of Easter Saturday. The Pontifical makes Pope Zosimus the author of this usage; but Baronius will have it more ancient, and quotes a hymn of Prudentius to prove it. That pope he supposes to have only established the use of it in parish churches, which, till then, had been restrained to greater churches. Papebroch explains the original of the paschal taper more distinctly, in his *Conatus Chronico-Historicus*, &c. It seems, though the council of Nice regulated the day on which Easter was to be celebrated, it enjoined the patriarch of Alexandria to make a yearly canon of it, and to send it to the pope. As all the other moveable feasts were to be regulated by that of Easter, a catalogue of them was made every year; and this was written on a taper, *cereus*, which was blessed in the church with much solemnity. This taper, according to Chastelain, was not a wax-candle made to be burnt; it had no wick, nor was it any thing more than a kind of column of wax, made on purpose to write the list of moveable feasts on, and which would suffice to hold that list for the space of a year. For among the ancients, when any thing was to be written to last for ever, they engraved it on marble or steel; when it was to last a long while, they wrote it on Egyptian paper; and when it was only to last a short time, they contented themselves to write it on wax. In process of time they came to write the moveable feasts on paper, but they still fastened it to the paschal taper. Such is the original of the benediction of the paschal taper.

TAPESTRY, a kind of cloth made of wool and silk, adorned with figures of different animals, &c. and formerly used for lining the walls of rooms, churches, &c. The art of weaving tapestry is supposed to have been borrowed from the Saracens; accordingly the workmen employed in this manufacture in France were formerly called Sarazins, or Sarazinois. Guicciardini ascribes the invention of tapestry hangings to the inhabitants of the Netherlands; but he has not mentioned at what time the discovery was made. This art was brought into England by William Sheldon, near the end of Henry VIII.'s reign. In 1619 a manufacture was established at Mortlake, in Surrey, by Sir Francis Crane, who received L.2000 from King James to encourage the design. The first manufacture of tapestry at Paris was established under Henry IV. in 1606 or 1607, by several artists whom that monarch invited from Flanders. Under Louis XIV. the manufacture of the Gobelins was instituted, which has introduced very beautiful cloths, remarkable for strength, for elegance of design, and a happy choice of colours. The finest paintings are copied, and eminent painters have been employed in making designs for the work.

Tapestry-work is distinguished by the workmen into two kinds, that of high and that of low warp; though the difference is rather in the manner of working than in the work itself, which is in effect the same in both; only the looms, and consequently the warps, are differently situated; those of the low warp being placed flat and parallel to the horizon, and those of the high warp erected perpendicularly. The English anciently excelled all the world in the tapestry of the high warp, and they still retain their former reputation, though with some little change. Their low warps are still admired; but as for the high ones, they are quite laid aside by the French. The French, before the revolution, had three considerable tapestry manufactures besides that of the Gobelins; the first at Aubusson in Auvergne, the second at Felletin in the Upper Marche, and the third at Beauvais. They were all equally established for the high and the low warp; but they had all laid aside the high warp excepting the Gobelins. There were admirable low warps likewise in Flanders, generally excelling those of France. The chief and almost only Flemish manufactures were at Brussels, Antwerp, Oudenarde, Lisle, Tournay, Bruges, and Valenciennes. The usual widths of tapestry are from two ells to three ells Paris measure.

The loom on which the high warp is wrought is placed perpendicularly: it consists of four principal pieces, two long planks or cheeks of wood, and two thick rollers or beams. The planks are set upright, and the beams across them, one at the top and the other at the bottom, or about a foot distance from the ground. They have each their trunnions, by which they are suspended on the planks, and are turned with bars. In each roller is a groove, from one end to the other, capable of containing a long round piece of wood, fastened in it with hooks. The use of it is to fix the ends of the warp. The warp, which is a kind of worsted, or twisted woollen thread, is wound on the upper roller; and the work, as fast as woven, is wound on the lower. In the inside the planks, which are seven or eight feet high, fourteen or fifteen inches broad, and three or four thick, are holes pierced from top to bottom, in which are put thick pieces of iron, with hooks at one end serving to sustain the coat-stave. These pieces of iron have also holes pierced, by putting a pin in which the stave is drawn nearer or set farther off; and thus the coats or threads are stretched or loosened at pleasure. The coat-stave is about three inches in diameter, and runs all the length of the loom. On this are fixed the coats or threads, which make the threads of the warp cross each other. It has much the same effect here as the spring stave and treddles have in the common looms. The coats are little threads fastened to each thread of the warp with a kind of sliding knot, which forms a sort of mesh or ring. They serve to keep the warp open for the passage of broaches wound with silks, woollens, or other matters used in the piece of tapestry. In the last place, there is a number of little sticks of different lengths, but all about an inch in diameter, which the workman keeps by him in baskets, to serve to make the threads of the warp cross each other, by passing them across; and, that the threads thus crossed may retain their proper situation, a packthread is run among the threads above the stick. The loom being thus formed, and mounted with its warp, the first thing the workman does is to draw on the threads of this warp the principal lines and strokes of the design to be represented on the piece of tapestry; which is done by applying cartoons made from the painting he intends to copy to the side that is to be the wrong side of the piece, and then, with a black-lead pencil, following and tracing out the contours of it on the thread of the right side; so that the strokes appear equally both before and behind. As for the original design by which the work is to be finished, it is hung up behind the workmen, and wound on a long staff, from which a piece is unrolled from time to time as the work proceeds.

Besides the loom, &c. here described, there are three other principal instruments required for working the silk or the wool of the woof within the threads of the warp; these are a broach, a reed, and an iron needle. The broach is made of a hard wood, seven or eight inches long, and two thirds of an inch thick, ending in a point with a little handle. This serves as a shuttle; the silks, woollens, gold, or silver, to be used in the work being wound on it. The reed or comb is also of wood, eight or nine inches long, and an inch thick on the back, whence it grows less and less to the extremity of the teeth, which are more or less apart, according to the greater or less degree of fineness of the intended work. Lastly, the needle is made in form of the common needle, only bigger and longer. Its use is to press close the wool and silks when there is any line or colour that does not fit well.

All things being prepared for the work, and the workman ready to begin, he places himself on the wrong side of the piece, with his back towards the design; so that he works as it were blindfold, seeing nothing of what he does, and being obliged to quit his post and go to the other side of the loom whenever he would view and examine the piece, to correct it with his pressing-needle. To put silk, &c. in the warp, he first turns and looks at the design; then taking a broach full of the proper colour, he places it among the threads of the warp, which he brings across each other with his fingers, by means of the coats or threads fastened to the staff; this he repeats every time he is to change his colour. Having placed the silk or wool, he beats it with his reed or comb; and when he has thus wrought in several rows over each other, he goes to see what effect they have, in order to reform the contours with his needle, if there be occasion. As the work advances, it is rolled upon the lower beam, and they unroll as much warp from the upper beam as suffices them to continue the piece: the like they do of the design behind them. When the pieces are wide, several workmen may be employed at once. We have but two particulars to add. The first is, that the high warp tapestry goes on much more slowly than the low warp, and takes up almost twice the time and trouble. The second is, that all the difference that the eye can perceive between the two kinds consists in this, that in the low warp there is a red fillet, about one twelfth of an inch broad, running on each side from top to bottom, which is wanting in the high warp.

The loom or frame on which the low warp is wrought, is much like that of the weavers. The principal parts are two strong pieces of wood forming the sides of the loom, and bearing a beam or roller at each end. They are sustained at bottom with other strong pieces of wood in the manner of trestles; and, to keep them the firmer, they are likewise fastened to the floor with a kind of buttresses, which prevent any shaking, though there are sometimes four or five workmen leaning on the fore-beam at once. The rollers have each their trunnions, by which they are sustained: they are turned by large iron pins three feet long. Along each beam runs a groove, in which is placed the wich, a piece of wood of about two inches diameter, and almost of the length of the roller: this piece fills the groove entirely, and is fastened from space to space by wooden pins. To the two wiches are fastened the two extremities of the warp, which is wound on the farther roller, and the work, as it advances, on the nearer. Across the two sides, almost in the middle of the loom, passes a wooden bar, which sustains little pieces of wood, not unlike the beam of a balance. To these pieces are fastened strings, which bear certain spring-staves, with which the workman, by means of two treddles under the loom, on which he sets his feet, gives a motion to the coats, and makes the threads of the warp rise and fall alternately. Each loom has more or fewer of these spring-staves, and each staff more or fewer coats, as the tapestry consists of more or fewer threads.

The design or painting which the workman is to follow is placed underneath the warp, where it is sustained from space to space with strings, by means of which the design is brought nearer the warp. The loom being mounted, there are two instruments used in working it, the reed and the flute. The flute does the office of the weaver's shuttle; it is made of a hard polished wood, three or four lines thick at the ends, and somewhat more in the middle, and three or four inches long. On it are wound the silks or other materials to be used as the woof of the tapestry. The comb or reed is of wood or ivory; it has usually teeth on both sides; it is about an inch thick in the middle, but diminishes each way to the extremity of the teeth: it serves to beat the threads of the woof close to each other, as fast as the workman has passed and placed them with his flute among the threads of the warp. The workman is seated on a bench before the loom, with his breast against the beam, only a cushion or pillow between them; and in this posture, separating with his fingers the threads of the warp, that he may see the design underneath, and taking a flute, mounted with a proper colour, he passes it among the threads, after having raised or lowered them, by means of the treddles moving the spring-staves and coats. Lastly, to press and close the threads of the silk or yarn, &c. thus placed, he strikes each course (*i. e.* what the flute leaves in its passing and coming back again) with the reed.

TAPOOL, a small island, one of the Sooloo archipelago, situated due south from the principal Sooloo Isle.

TAPOPO, a small low island in the Eastern Seas, on the west coast of the island of Waygiou, covered with trees to the water's edge.

TAPPA, one of the small Molucca Islands, separated from that of Lata by a channel in some places not above forty yards wide and one and a half long, with deep water. Long. 123. 35. E. Lat. 0. 6. N.

TAR, a thick, black, unctuous substance, obtained chiefly from old pines and fir trees by burning them with a close smothering heat. It is prepared in great quantities in Norway, Sweden, Germany, Russia, and North America, and in other countries where the pine and fir abound. Becher the celebrated chemist first proposed to make tar from pit-coal. Manufactures for this purpose were established many years ago in the bishopric of Liege, and in several parts of England. In the year 1781, the earl of Dundonald obtained a patent for extracting tar from pit-coal by a new process of distillation. Great hopes were entertained of the value of this discovery, but we have not heard that it answered his expectations. Tar, which is well known for its economical uses, is properly an empyreumatic oil of turpentine, and has been much used as a medicine both internally and externally. Tar-water, or water impregnated with the more soluble parts of tar, was formerly a very popular remedy, and was most earnestly recommended by Bishop Berkeley.

TARABAD, a town of Hindustan, in the Mahratta territories, in the province of Aurungabad, ninety-four miles south-east from Surat. Long. 74. 20. E. Lat. 20. 38. N.

TARAHPOOR, a town of Hindustan, province of Bahar, ninety miles south-south-east from Patna. Long. 86. 40. E. Lat. 25. 7. N.

TARANTELLA, a lively Neapolitan dance, the melody in $\frac{6}{8}$ time.

TARANTO, a city of Italy, in the Neapolitan province of Otranto. It stands on a rocky island near to Cape St

Vito, but is joined to the continent by a long bridge. It is surrounded with walls, and defended by batteries and a strong castle. It is the capital of a district, is the seat of an archbishop, and contains a cathedral, several churches and monasteries, an orphan-house, a naval hospital, and two Latin schools. It is irregularly built, and occupies but a small part of the ancient Tarentum. The harbour is now nearly filled with sand, but is accessible and secure for vessels of light draught of water, and for the craft of the numerous fishermen. About sixty coasting vessels belong to the port, trading, for the most part, in the Adriatic Sea. The city is supplied with water by means of an aqueduct. It contains 14,150 inhabitants, employed in trade in corn and oil, and other products of the land, in the fishery, and in making some cotton goods and hats, and in collecting salt. Long. 18. 25. E. Lat. 40. 45. N.

TARARE, a town of France, in the department of the Rhone and the arrondissement of Villefranche. It stands at the foot of a mountain on the river Tardine, and has extensive manufactures of muslins, printed cottons, mixed cloths of wool and cotton, and considerable tanneries. It contains 6250 inhabitants.

TARASCON, a town of France, in the department of the Mouths of the Rhone and the arrondissement of Arles. It stands on the left bank of the Rhone, over which is a bridge of boats leading to Beaucaire. It is a well-built place, and has a castle, from the platform of which a fine prospect is to be seen. It contains 12,500 inhabitants, who have considerable trade in woollen and cotton goods, in making brandy, and in ship-building. Long. 4. 34. 31. E. Lat. 43. 48. 20. N.

TARBES, an arrondissement of the department of the Upper Pyrenees, in France. It is 484 square miles in extent, is divided into eleven cantons, and these into 197 communes, containing, in 1836, 110,542 inhabitants. The capital is the city of the same name, which is that also of the department. It is situated on a fine plain on the left bank of the Adour, is well built, with good paved streets, has a cathedral and two churches, a theatre, a hospital, and a fine market-place. The inhabitants amounted in 1836 to 12,630, who are chiefly employed in making hardware and leather. They have also a considerable trade with Spain. The prospects from the bridge towards the Pyrenees are very fine. It was the seat of the war during the duke of Wellington's campaign in France. Long. 0. 1. 32. W. Lat. 43. 14. 2. N.

TARDEBIG, a town of the hundred of Halfshire, in the county of Worcester, 113 miles from London. It has no market, and only derives some trade from the canal which passes by it from Birmingham. The inhabitants amounted in 1831 to 4145.

TAREM, a town of Persia, in the province of Laristan, situated in a plain on the banks of a salt river. It is a meanly built place, consisting of a mud fort, surrounded on all sides by wretched huts, but is populous, and contains many respectable merchants, who trade to Muscat, Gombroon, and Shiraz.

TARENT, an island on the western shore of the Persian Gulf, immediately opposite Katif. It is about seven miles in length and as many in breadth, is well supplied with fresh water, and embellished with many delightful gardens, which produce abundance of fruit.

TARGUM, a name given to the Chaldee paraphrases of the books of the Old Testament. They are called paraphrases or expositions, because they are rather comments and explications than literal translations of the text. They are written in the Chaldee tongue, which became familiar to the Jews after the time of their captivity in Babylon, and was more known to them than the Hebrew itself; so that when the Hebrew text was read in the synagogue, or in the temple, they generally added to it an explication in the Chaldee tongue for the service of the people, who had but a very imperfect knowledge of the Hebrew. It is probable, that even from the time of Ezra this custom began; since this learned scribe, reading the law to the people in the temple, explained it with the other priests that were with him, to make it understood by the people (Nehem. viii. 7–9).

But though the custom of making these expositions in the Chaldee language be very ancient among the Hebrews, yet have they no written paraphrases or targums before the era of Onkelos and Jonathan, who lived about the time of our Saviour. Jonathan is placed about thirty years before Christ, under the reign of Herod the Great. Onkelos is somewhat more modern. The Targum of Onkelos is esteemed most of all, and copies are to be found in which it is inserted verse for verse with the Hebrew. It is so short and so simple, that it cannot be suspected of being corrupted. This paraphrast wrote only upon the books of Moses; and his style approaches nearly to the purity of the Chaldee, as it is found in Daniel and Ezra. This targum is quoted in the Misna, but was not known either to Eusebius, Jerom, or Origen.

The Targum of Jonathan, son of Uziel, is upon the greater and less prophets. He is much more diffuse than Onkelos, and especially upon the less prophets, where he takes great liberties, and abounds in allegories. His style is tolerably pure, and approaches pretty near to the Chaldee of Onkelos. It is thought that the Jewish doctors who lived above 700 years after him made some additions to his work.

The Targum of Joseph the Blind is upon the Hagiographa. This author is much more modern and less esteemed than those whom we have now mentioned. He has written upon the Psalms, Job, the Proverbs, the Canticles, Ecclesiastes, Ruth, and Esther. His style is a very corrupt Chaldee, with a great mixture of words from foreign languages.

The Targum of Jerusalem is only upon the Pentateuch; nor is that entire or perfect. There are whole verses wanting, others transposed, others mutilated; a circumstance from which many have supposed that this is only a fragment of some ancient paraphrase that is now lost. There is no targum upon Daniel, or upon the books of Ezra and Nehemiah.

These targums are of great use for the better understanding, not only of the Old Testament, on which they are written, but also of the New. As to the Old Testament, they serve to vindicate the genuineness of the present Hebrew text, by proving it to be the same that was in use when these targums were made, contrary to the opinion of those who think the Jews corrupted it after our Saviour's time. They help to explain many words and phrases in the Hebrew original, and they hand down to us many of the ancient customs of the Jews. And some of them, with the phraseologies, idioms, and peculiar forms of speech, which we find in them, do in many instances help as much for the better illustration and better understanding of the New Testament as of the Old; the Jerusalem Chaldee dialect, in which they are written, being the vulgar language of the Jews in our Saviour's time. They also very much serve the Christian cause against the Jews, by interpreting many of the prophecies of the Messiah in the Old Testament in the same manner as the Christians do. Many instances are produced to this purpose in Dr Prideaux's Connection of the History of the Old and New Testament, vol. ii. p. 549. These targums are to be found in the second edition of the great Hebrew Bible, published at Basel by Buxtorf the father in 1610. He has rectified the Chaldee text, and reformed the vowel pointings in it; the targums having at first been written without vowel points, which were afterwards added very erroneously by some Jews.

TARIFF, a table containing the names of different sorts of merchandise, with the duties to be paid as settled among trading nations.

TARN, a department of the south-west of France, formed out of a part of ancient Languedoc. It is bounded on the north and north-east by the department of Aveiron, on the south-east by Herault, on the south by Aude, on the west by Upper Garonne, and on the north-west by Tarn-Garonne. Its area contains 573,977 hectares, equal to 1,363,942 acres, or 2131 square miles. It comprehends four arrondissements, thirty-five cantons, and 327 communes. The population in 1836 amounted to 346,614 persons, of whom about 40,000 are Protestants, and the remainder adhere to the Roman Catholic church. The face of the country is a mixture of plains, hills, valleys, and some few mountains, mostly covered with woods. These are branches from the Sevennes and Lozere chain, which in this department has the name of *Montagne Noire*, and extends on the south side into the departments of the Upper Garonne and the Aude. The chief river gives its name to the department, and receives the waters of the Rance and the Agout, and is navigable from Guillac to its mouth. The northern division is in part watered by the Aveiron and the Viaur. The climate is mild and healthy, with summers of great heat, and with winters of very short duration, unattended by any severe frosts. The soil is generally fertile in corn, and produces more grain, especially wheat, than is consumed within the department. In the higher parts of the department rye is found to succeed better than wheat; but the quantity raised of both is usually about equal. In the lofty districts the pasture is good, but in the lower districts the plains are burnt up in the summer, and the cattle, though good, are small in size. The husbandry work is chiefly performed by asses or mules. There are but few sheep; and no care has hitherto been taken to improve either the flesh or the wool. Swine are very abundant, and geese still more so; and large quantities of both are cured by smoking, and form a valuable article of export. It is said not to be uncommon to see fat geese weighing as much as thirty pounds, the livers of which are considered a great luxury. Fruit is abundant, especially plums, cherries, and chestnuts; and woad, anis and coriander seed, liquorice and saffron, are carefully cultivated. The wine is extensively made, some of good quality; that near Guillac is highly esteemed, and is principally purchased for the Bordeaux market, to be shipped to foreign countries. Silk was once extensively obtained, but that commodity has of late years much declined. Mines of copper and of lead were formerly worked, but have now ceased; and the only mineral produced is iron, and that in very small quantities. The manufacturing industry is confined to the towns of Albi and Castres, and to the more hilly districts. The inhabitants produce woollen stuffs and serges, silk and cotton goods. The tanneries are numerous, and make more than sufficient leather for the domestic consumption. The department sends two deputies to the legislative chamber. Castres is the capital town, and had 17,602 inhabitants in 1836.

TARN AND GARONNE, a department of the south-west of France. In 1808 it was formed out of portions of the several existing departments of Lot, Upper Garonne, Lot-Garonne, Gers, and Aveiron. In times before the revolution it was known as the Agenois, Lomagne, and Basse Marche du Rouergue of Upper Languedoc. According to its present state, it is bounded on the north by the Lot, on the east by the Aveiron and the Tarn, on the south by the Upper Garonne, and on the west by the Gers and the Lot-Garonne. Its area contains 366,976 hectares, equal to 872,440 acres, or 1363 square miles. It is divided into three arrondissements, twenty-four cantons, and 191 communes, with 242,184 inhabitants in 1836, who chiefly adhere to the Roman Catholic church, but among whom are between 30,000 and 40,000 Protestants. The face of the country consists of several extensive plains, about 1000 or 1200 feet above the level of the sea, with valleys of various extent intersecting them, through which their several streams flow. The principal rivers are the Garonne, the Tarn, and the Aveiron. The soil is various in fertility, but on the whole is productive. The plain of the Garonne is peculiarly so, and on both sides is lined with hills, which are covered with fruit trees and vineyards. The banks of the other two streams are rich, and present most picturesque prospects. Many of the farms on the Garonne are sold as high as from L.50 to L.60 the English acre. The climate is temperate, and sometimes the winter passes without snow, and the streams are scarcely ever frozen; but violent storms of hail, collected on the Pyrenees, occasionally descend and destroy the hopes of the cultivators. The business of agriculture is conducted with great care, and on the best of the soil the practice of fallowing is abandoned; but on the inferior land a year's fallow is succeeded by two corn crops, as in most of the other parts of France. Much good wheat is raised, and the best of it is converted into flour for the West India markets. Other kinds of grain are raised with success. Fruit is abundant, and forms articles of export when preserved, especially the plums and figs. Almonds, chestnuts, and walnuts, are also collected for trade, with abundance of wine, and wood for fuel and building. The only mineral procured is iron, and of that but little; but there are valuable quarries of marble, and some of millstones. Next to wheat, the amount of the value of the wine exceeds that of all the other products. There are manufactories of linen and woollen cloths, of china and earthen ware, of paper, cutlery articles, leather, and some silk goods. The three rivers already mentioned are navigable, and afford the greatest advantage to commerce by the facilities which they offer for the distribution of the heavy productions of the department. The capital is the city of Montauban, and it is also the chief seat of manufacturing industry. Its population in 1836 amounted to 23,865.

TARNOPOL, a circle of the Austrian kingdom of Gallicia, extending over 1317 square miles, comprehending four cities, six market-towns, and 251 villages, with 189,600 inhabitants. The capital is the city of the same name, on the river Sereth. It contains 1080 houses, with 7560 inhabitants, of whom many are Jews, who carry on an active internal trade. It has also some tanneries.

TARNOW, a circle in the Austrian kingdom of Gallicia, extending over 2040 square miles. It contains three cities, eleven market-towns, and 464 villages, with 215,000 inhabitants, of whom 15,000 are Jews. The capital is the city of the same name, which contains 360 houses, with 4540 inhabitants, employed in making table and other linens, and having extensive tanneries. Long. 20. 55. E. Lat. 49. 59. N.

TARPA, Spurius Mecius, a Latin critic in the time of Julius Cæsar and Augustus. He had his tribunal in the temple of Apollo, where, with four assistants, he passed sentence on the works of the poets. Cicero and Horace make honourable mention of this critic.

TARPAULIN, a piece of canvass, well tarred over to keep off the rain from any place. The term is applied in a burlesque sense to a person that has been all his life bred to the sea.

TARPORLEY, a town of the hundred of Eddisbury, in the county of Chichester, 179 miles from London. It has some small manufactories of stockings and leather breeches. The population amounted in 1821 to 800, and in 1831 to 995; but the parish contains 2391.

TARRAGONA, a city of Spain, in the province of Catalonia. In the period when the Romans governed Spain, this city was very celebrated as the capital of that division of the kingdom which is to the east of the Ebro, then denominated Tarraconia. The streets are narrow, and the houses lofty. It is the see of an archbishop; but the cathedral, though large, is by no means handsome. It is a place of considerable trade, especially in brandies, great quantities of which, made in the plain near it, are shipped from its port. It has considerable manufactories of silk goods of various kinds; and the whole population displays a degree of industrious activity by no means usual in Spain. The best-tasted brandies are those from the hills belonging to the Carthusian convent, on the borders of the Campo; but those of the Campo are stronger. When first made, they are all as white and transparent as water; but by keeping in casks, and by artificial means, they become darker coloured before they arrive at the markets for sale. The city of Tarragona, as well as the country around it, abounds with Roman antiquities, whose investigation has always been a favourite pursuit with the more studious of the inhabitants. The city within the walls contains a population of only ten thousand; but the far greater number of inhabitants reside in the suburbs. Long. 1. 46. 37. E. Lat. 41. 7. 6. N.

TARSUS, a large city of Asia Minor, the ancient capital of Cilicia, situated on a fertile plain on the right bank of the Cydnus, about six miles from its mouth. The town is partly surrounded by a wall, supposed to be the remains of that erected by Haroun al Raschid. The houses, which seldom exceed one story in height, are flat-roofed, and mostly constructed of hewn stone derived from the ruins of the ancient edifices. The city contains two public baths, a number of mosques, several handsome caravanserais, and a small ancient church. There is a castle, said to be built by Bajazet. On an eminence to the southwest are the ruins of a spacious edifice, which may probably have been the gymnasium; and about 200 yards farther to the west, an ancient gateway stands almost entire. The city contains about 30,000 inhabitants during the winter, among whom are 200 Armenian and 100 Greek families; while a considerable proportion consists of Toorkomans, who migrate with their families to the mountains. A considerable trade is carried on. The land in the neighbourhood is exceedingly fertile, and yields abundance of wheat, barley, sesame, and cotton, which are exported to Malta, and thence to Spain and Portugal. Copper from Maden, and gall-nuts, are also exported in large quantities. The imports consist chiefly of rice, sugar, and coffee. Tarsus is a city of high antiquity. It is said by Arrian and Strabo to have been built by Sardanapalus, though others consider it to have been a Grecian colony. It was much favoured by the Roman emperors Augustus and Adrian; and, in wealth and grandeur, as well as in literature and science, rivalled the more celebrated cities of antiquity. It was adorned with many magnificent edifices, the monuments of ancient taste; but has been subject to so many vicissitudes, that scarcely any relics of its former splendour are to be seen.

TARTARY, a tract of territory in central Asia, of which the limits have never been exactly defined. It is generally understood to embrace that wide space which intervenes between the dominions of Russia and China on the west and east, and which on the south is bounded by the kingdom of Persia and the lofty central mountains of Asia. This vast space was formerly occupied by pastoral tribes, who, united under one great chief, assailed and finally overthrew the Roman empire; and who afterwards, under their great leader Ghenghis Khan, carried their devastations both into Europe and Asia. Central Asia is one vast meadow, extended on a dead level to an almost boundless extent, covered with flocks and herds, and necessarily the habitation of a pastoral people. Such has accordingly been the character of the Tartars from time immemorial; their sole employment being to tend their flocks and herds, and occasionally to hunt the wild animals of the forest; living in tents in the open fields, without towns or villages; delighting in horsemanship, and in all manly and warlike exercises; and having a breed of the finest horses in the world. "The fancy of the poet," says the Roman historian, "has clothed the pastoral life in the fairest attributes of innocence and peace; but it is the province of history to exhibit a different picture, and to exhibit these shepherds as they truly are, fierce, bloody, savage, and vindictive." The Tartars were accordingly known in ancient history under the appellation of Scythians, and were admired for their warlike virtues and for the simplicity of their manners, for their hospitality, and their ignorance of money and luxury, by the Greek legislators of Athens and Sparta, whose policy it was to form a community on the same warlike model, where nothing was to be seen but

Man and steel, the soldier and his sword.

They were at all times the most formidable enemies of civilized life, and the various inroads into their dominions by the greatest conquerors only ended in disaster and defeat. As light troops, they were most formidable in the ancient wars; and the Persian monarchs, with their well-trained bands, and even Alexander of Macedon, were forced to retreat before their formidable though desultory attacks.

While Rome retained the vigour and simplicity of her republican institutions, and the iron discipline of her armies, the rude assaults of these barbarians were invariably repelled; but when the warlike habits of the Romans began to be corrupted by the progress of luxury, their attacks were renewed with increased fierceness, and with greater chances of success. Numbers of the first invaders perished in the inroads into the Roman provinces. But these being still reinforced with increasing multitudes, while the vigour of the defence was relaxed, they at length effected permanent conquests; and, under the appellation of Huns, finally extended their ravages over all Italy. The intelligence of their success, and of the riches and beauty of the conquered countries, attracted multitudes from the remote extremities of Asia, and under their repeated assaults the empire of the west was subverted. This event was hastened by the dreadful invasion of Attila, who was characterized as "the sword of God and the destroyer of nations." On the east the Tartar tribes, under the appellation of Toorks or Turks, from Chinese or Independent Tartary, poured their innumerable hordes on the Persian empire, where they established a dynasty celebrated under the name of the Seljukian. About the end of the tenth century, they crossed the Euphrates in four divisions under different leaders, and invaded Asia Minor and Syria, of which they conquered and retained possession of the finest provinces. They endured various vicissitudes, and were at one time reduced very low. But being directed by able leaders, they recovered the ascendant; and, their numbers being swelled by the warlike and migratory population which, in the course of long wars, was scattered over those countries, they finally succeeded in overturning the eastern empire, and Constantinople became, and still continues, the seat of their empire. In the twelfth century the Tartar tribes were still more formidable. Their whole power being consolidated under Zingis or Ghenghis Khan, they successively conquered China, Persia, and all central Asia from the Black Sea to eastern Asia. His successors pursued the career of conquest, and added Russia and Poland, with part of Germany. A general panic was now diffused over the whole civilized world by the intelligence of these conquests, and of the ravages committed by these barbarians in the fairest portions of the earth. The great empire of Ghenghis Khan was broken into divisions; but the different chiefs who now reigned were still eager for conquest; and Timur the Tartar, or Tamerlane, having established his dominions over a large and fertile portion of

Asia, conquered Persia, where the degenerate chiefs of the race of Ghenghis still bore sway, broke the power of the Turks in Asia Minor, ravaged and conquered India, and in that country established a dynasty which continued till the close of the last century, when every minor authority in that part of Asia was swallowed up by the extending sway of Britain, on whose bounty the great Mogul, the descendant of Ghenghis, is now a humble pensioner. China fell an easy prey to these conquering hordes, and has long been the seat of a Tartar dynasty, having been conquered about the sixteenth century by the Mantchoos, a tribe which issued from the north, near the coasts of the Eastern Ocean. But the rising power of Russia has reduced most of those wandering tribes under her dominion; and the reign of Independent Tartary is now contracted within a narrow span. The progress of civilization, and the improvement of the art of war by the invention of fire-arms, have entirely broken the power of these savage hordes. The Russian cannon now forms a sure barrier against the incursions of the Tartar horse; and under her growing civilization and military power, the fiercest tribes have been taught to tremble and obey. All northern Asia, to the limits of China, and eastward to the Pacific Ocean, has been reduced under the power of Russia; and the narrow space that is now occupied by Independent Tartary is ruled by numerous petty sovereigns, who are often engaged in mutual wars, and can never be again formidable to the civilized states of Europe. On the contrary, the rude tribes of Asia will hardly be able to maintain their ground against the encroaching flood of European civilization or of European arms. The powers of Europe seem now to have imbibed the spirit of conquest which formerly propelled the Asiatic hordes into the seats of European civilization; and the late unsuccessful expedition of the Russians from the west to Khyvah, about 240 miles east of the Caspian Sea, and the bold and admirably conducted inroad of the British from the east as far as Candahar and Caubul, are among the fruits of this ambitious policy.

This extensive country may be divided into Independent Tartary and Chinese Tartary.

I. Independent Tartary includes that extensive region which stretches from the Caspian Sea, as far east as the great Himalaya range of mountains, which runs through the centre of Asia, and from which a branch diverges from the main ridge, under the designation of Beloor Taugh, northward, and separates Independent Tartary from the country of Kashgar and from Chinese Tartary. On the south, this country is indistinctly bounded by Persia, and on the north by the provinces of Oufa, Orenburg, and Tobolsk, belonging to Asiatic Russia. Independent Tartary is divided into various states; namely, 1. Khyvah, which is a stripe on the banks of the Oxus, of which the length does not exceed between 200 and 300 miles, and the breadth in no place more than fifty. 2. The kingdom of Bockhara or Bukharia, which is by far the most important both in power and extent. The habitable part of this kingdom is small in proportion to the desert with which it is chiefly surrounded, and which may be considered in a great measure as its boundary. It is divided from Khyvah on the west and north-west; to the north-east stretch vast tracts of desert, thinly sprinkled with the tents of the Toorkoman and other tribes, and only interrupted by the stream of the Jaxartes; on the east it is bounded by Kokaun; and the Oxus, with the mountains from which it flows, may be said to form its southern boundary. The limits of this kingdom are, however, in a state of fluctuation, varying, as is generally the case in the disorderly regions of Asia, with the success of its arms; so that they can hardly be laid down with any precision. 3. The independent state of Kokaun, which is fully 250 miles in length by 150 in breadth, is bounded on the east from Bockhara by a steep and inaccessible chain of mountains, the two countries being divided by the White River; on the south it has the mountainous tract which divides it from Buduckshan and Chitral; on the south-west it is bounded by Kurratageen; on the east and north-east by mountains tributary to China, and inhabited by Kirgeesh and Kuzaks; on the north-west by the district of Tashkund, with mountains and deserts. South and east of Bockhara lies the large and interesting province of Balk; and about 600 miles east of Kokaun lie the Mahommedan states of Kashgar and Yarkund.

One of the great peculiarities of Asiatic manners, well calculated to attract attention, is the division of the population into the two classes of fixed and wandering communities. In the richer countries to the south and east of Asia the inhabitants are mostly stationary, dwelling in fixed habitations, and occupied with trade and agriculture; but the northern and western parts, including Arabia, Persia, a portion of Afghanistan, Balk, and all the country that lies in the same parallel of latitude, as far east as the most civilized parts of China, and on th west including a portion of Poland and Russia, have been occupied by wandering tribes, migrating with the winter and summer in quest of pasture, and having no fixed habitations in towns and villages. This class has been gradually diminishing with the progress of civilization. But in the country we are now describing, the pastoral life is still seen in its original rudeness and simplicity; and in many districts those shepherds discover all the cruelty and ferocity of the Tartar tribes. The original invaders were the Mongoles from the eastern regions bordering on China; but they have been supplanted in their turn by other invaders, and the country is chiefly occupied by the Toorkomans, and the Oosbecks or Usbecks, and other rude tribes. The Toorkomans are divided into other tribes, the three principal of which are, the Tuckeh, the Gocklan, and the Yamoot. They occupy the country to the north of the Elburz range of mountains, and of Persia, and are found as far north as Khyvah, all along the shores of the Caspian Sea. They are extremely barbarous and cruel in their manners. They live partly by plunder, and pour down from their deserts upon the cultivated countries around, plundering villages and caravans with every circumstance of atrocious outrage, murdering on the spot the old, the feeble, and the helpless. Those who are fit for labour they carry into slavery. They have depopulated many extensive districts, which but for them would continue fertile and inhabited. The Toorkomans, and most of the tribes in the same quarter, are Mahommedans of the sect of Soonies; the Persians again are Sheahs, and the deadly hatred which prevails between these sects may exasperate the fury of their invaders, and add to their cruelties. On the east, there are other tribes who commit the same ravages. The captives that are carried off are disposed of to slave-merchants, and are by them sold in the great slave-markets of Khyvah and Bockhara. All these tribes are described by Fraser[1] as cruel, blood-thirsty, and rapacious, even in their private lives and domestic relations. They set no value whatever on human life; and a word, a look, or some trivial mistake, he observes, is apt to occasion bloodshed. A Toorkoman will put to death his wife, his child, or his servant, for the merest trifle; and if crimes of this sort do not more frequently occur, it is more from considerations of interest than from any regard to the ties of blood or affection. "Even the wars between the tribes," observes this judicious writer, "have assumed the same cruel and rapacious character which marks their foreign warfare; avarice has quite overpowered religious zeal; and the unholy practice of selling captives of their own faith is now frequent."

---

[1] Fraser's Narrative of a Journey into Khorassan, chap. xii.

The tribe of Tuckeh is the most numerous of the Toorkoman tribes, containing 40,000 families. They are a treacherous and faithless race, and never suffer an opportunity to escape of plundering even their friends. The Gocklans were formerly powerful, but their power has been broken by adverse events, and they now acknowledge the Persian supremacy. The Yamoot tribe is divided into two parts: the one, amounting to 15,000 families, acknowledges the Persian monarch; the other, amounting to 16,000 families, is subject to Khyvah. All these tribes resemble each other in their customs and manners. They live in tents or portable houses, and frequently change their stations, as pasture becomes scarce, seldom remaining more than five or six days in one place. They encamp in parties of from 30 to 200 families; each party is ruled by its elder, whose advice is taken in all matters affecting the interests of the community, and who adjusts petty disputes; but they have no governors, chiefs, or nobles among them, nor would they endure any one arrogating such superiority. The same spirit of equality prevails in common life, no distinctions of rank being at any time observed, nor any great deference to the claims of age or relationship. Like all rude tribes, the Toorkomans pique themselves on hospitality; but so vitiated have their morals become by the love of plunder, that even this tie is often violated.

The wealth which they acquire by perfidy and rapacity, they generally invest in such property as camels, horses, valuable swords, arms and armour, women's ornaments, clothes, jewels of gold or silver, and rich furniture. The women are not concealed, as in Mahommedan countries; nor do they wear veils. Their dress consists of a long loose vest or skirt, with sleeves, which covers the whole person down to the feet, and is open at the breast in front, but buttons or ties close up to the neck. It is made of silk or cotton stuff, red, blue, green, striped red or yellow, checked, or variously coloured. Underneath are drawers of silk or cotton. Their head-dress is a lofty cap with a broad crown, made of light chips of wood or split reeds covered with cloth. With respect to the dresses of the men, those of the poorer class consist of a stout woollen shirt, and a pair of woollen drawers, or a long brown woollen wrapper; but the better classes have generally adopted the common Persian habit. There is much individual variety among those tribes. The Tuckehs have a good deal of the Tartar physiognomy. Many of them are tall, stout, and well made, with scanty beards, small eyes drawn up at the corners, high cheek-bones, and small flat noses; all the true features, in short, of a Tartar face; while others have handsome features, more resembling a European than an Asiatic countenance. The Gocklans also bear traces of a Tartar origin, but less than the Tuckehs, while there are remarkable differences among them, marking the intermixture of different races. The Yamoot men have less of the Tartar physiognomy than any of the other tribes. Many of them resemble the Persians, and also the Russians, in a certain harsh irregularity of feature which they possess. They are all ferocious and warlike in their habits. Their arms are a spear and sword, in the use of which they are sufficiently dexterous. The sword is generally formed in the curved Persian fashion, and very sharp. They also wear a dagger. Fire-arms are as yet not in general use among them. The Gocklans and Yamoots use bows and arrows, in the use of which they are not nearly so dexterous as their ancestors. These tribes are all excellent horsemen, and they possess a race of horses which are celebrated all over Asia. They greatly value size and bone, which are indigenous to the country; but figure and blood, borrowed from the Arab breed, much more. Their horses are capable of enduring extraordinary fatigues. When properly trained for a plundering expedition, they will carry their riders without flagging for eight days together, at the rate of from eighty to a hundred miles per day. Those of the best breeds cannot be purchased under L.150 or L.200. For the protection of their flocks they have a breed of very large and fierce dogs, which assist their shepherds in managing their flocks. But though they attend to their flocks, they still delight in plunder, to which they look for riches and extraordinary indulgences; and when they resolve on any expedition, they unite under some leader whose conduct and courage inspire them with confidence; and, sallying from their haunts, they move with astonishing celerity into some of the frontier provinces of Persia. They lie near the gates of the town or village which they have marked out for their prey; and watching in silence until dawn, when the unsuspecting inhabitants begin to issue from the gates to pursue their daily labour, they start from their lurking place, seize all they can catch, murder those who resist, rapidly plunder the houses, and, binding their booty on the cattle, hasten to retreat before the country is alarmed. They massacre the old and infirm; and those who are taken captive to be sold for slaves, they fasten by ropes to their horses, with their arms tied behind their backs; and they drive them on with blows of heavy whips to increase their speed. They have a few manufactures, such as carpets, which they weave of a very beautiful fabric, and which are highly valued, and bring high prices. They also weave cloth of camels' hair, and coarse woollens chiefly for their own use; and they dispose of butter and cheese, the produce of their flocks.

A large portion of Independent Tartary, farther to the east of the Caspian, in the neighbourhood of Bockhara, Balk, and Samarcand, countries which lie near the river Oxus, is inhabited almost entirely by the Oosbecks, a people of the widely extended race of the Turk or Toork, but whose original seat is not precisely ascertained. They appear to have come from the north, and to have been tempted from their original and inhospitable abodes by the finer countries on the plains of the Oxus and the Jaxartes. Like the other Turks, they are celebrated all over the east for their fine appearance, which is remarkably contrasted with the Mongoles, Kalmucks, and other Tartar tribes. They are distinguished by broad foreheads, high cheek-bones, thin beards, and small eyes; by a clear and ruddy complexion, and generally by black hair. The women are fair and beautiful. Their dress resembles that of the Toorkomans of the desert. They wear a lofty cap upon the head, with a handkerchief over it. The shirt and trousers, with the gown, are not unlike those of the men. The dress of the latter at Khyvah consists of a shirt and drawers of white cotton cloth, with two or three gowns over them of striped silk stuff, blue, red, and gray, all open at the breast, so that when the girdle is loose the person is very indecorously exposed. A broad-topped sheep-skin is worn upon the head. The khan is hardly to be distinguished by his dress from his subjects; but on grand days he wears a small jewel in his turban, with a gold-embroidered Oosbeck gown over his white shirt and drawers; and the other ensign of royalty which he assumes, is a tuft of gold and jewels upon his horse's head.

The Oosbecks at Khyvah are described as a very uncivilized race, gross in their domestic habits, and coarse and disgusting in their food and manner of eating; the khan, his ministers, and almost all his nobles, being fat and unweildy, owing to their habits of indolence. There is little distinction between the different ranks of society; the master and servant, the chief and the groom, standing or sitting promiscuously together. In Bockhara, where the Oosbecks constitute the chief portion of the population, along with the Taujicks and Toorkomans, they are represented by Fraser as honest, just, sincere, good tempered, generally well disposed, and by no means either cruel or treacherous; rarely quarrelling, and their quarrels rarely stained with blood; nor are they addicted to private and murderous revenge, like most of their neighbours. They are fond of horse-flesh, which they prefer to beef; and by their fondness for the intoxicating drink called mare's milk, they are often seduced into excess and drunkenness. They are likewise fond of tea. They are the chief inhabitants of Kokaun, and other districts to the east, and are there represented as a fat, fair, and high-complexioned people, extremely quiet, good humoured, and hospitable; very fond of riding, hunting, hawking, and getting drunk on *kimmiz*, or mare's milk. The other wandering tribes who are scattered over this country are also described as peaccable and honest. The Oosbecks who inhabit the desert tracts of the country, live in parties of from two hundred to above one thousand families. These parties have no particular chief, but each is regulated in all its concerns by a bey or beg, who is chosen by common consent, on account of his wealth, character, or abilities. In the larger divisions, the king has a voice in the election of the bey or chief, but in the smaller divisions this is little attended to. These chiefs decide in all disputes which are not of great importance. In serious cases several of them consult together; and if they cannot agree they remit the matter to the cauzee, who is always appointed by the king, and is held in considerable awe. In all the different states, the king or chief is perfectly absolute, the fountain of all authority and power. The only restraint on his will is derived from the influence of religion; the oleemut and heads of religion alone possessing any authority or respect, to which it is necessary for the king to defer. The influence of this body, however, has been of late so much weakened, that some of them have been put to death by the reigning monarch. The priests rank above all classes, civil as well as military. The nobles belonging to the army occupy the second rank. The revenue is collected by the bey in kind; namely, sheep, camels, oxen, and other animals, in the proportion of one in forty. He fixes a price on them, and the tribute is paid in money to a collector sent with another legal officer and ten soldiers to receive it. In order to preserve his control, the king discourages different tribes from living together in the same union; but it is common in the desert to see a variety of tribes mingled together. The tents of the Oosbecks consist of a frame-work of thin laths covered with thick black felt, and these are called kirgahs or black houses. The floors of the rich are spread with carpets and numuds; those of the poor with a blanket or mat of camel's hair; and a hole in the roof, of open lattice-work, is the only chimney, over which they draw a piece of black felt when it rains. The dress of the Oozbecks in Bockhara consists of the same loose and flowing garments as in most parts of Asia. They were a shirt and drawers, of cotton in summer and of woollen in winter, and over these a silk or woollen wrapping gown, tied round the waist with a girdle; and in winter a sheep's skin, or a coat of thick felt, in which they wrap themselves. The head-dress is in summer a painted cap of silk, which they call a calpak, and in winter a small cap of broad cloth lined with fur; a checked or white turban is often worn round this, and forms the true national dress. Bandages of cloth rolled round the legs form a rude substitute for stockings; or boots are worn, of brown leather, reaching up to the knee. The dress of the women is very similar to that of the men. They wear boots and silk gloves, and throw over the person a silk sheet, which conceals them from head to foot, a small orifice being left for the eyes. They are fond of ornaments, wearing necklaces of gold beads, with nose-rings and ear-rings. In the country the women wear no veils, but go about openly as in Europe. The Taujicks are a peaceable class, who are understood to be opposed to the Toorks or Toorkomans, and the Oozbecks, and other wandering hordes, who, under various designations and subdivisions into tribes, form a scanty population, inhabiting chiefly the banks of the Oxus, and the habitable spots scattered through the desert; but they are to be found in greater or smaller numbers, according to the quantity of cultivated land, all over the more fertile and well-watered country to the south and south-east of Bockhara.

The towns of Tartary are, Khyvah, Ourgunge, Hazarasp, Zercaun, Pitnuck; Bockhara, Balk, both large towns; Samarcand, now ruined and in a state of decay, though still containing many fine buildings; Kokaun, Khojund, Yarkund, and others of less consequence. Of the commerce of this distant region, some account has been given under the articles Bukharia and Balk. The Russians have long carried on commerce with Khyvah and the western parts of Tartary. The possession of the port of Astracan, and more lately those of Bako, Salian, Derbund, and Lankeran, has given them an entire command of the navigation and commerce of the Caspian Sea; and it is long since they began to build forts on its eastern shore. The principal of these is Okh Trappeh, not far from Astrabad, and some miles to the north of Attruck, in the territory of the Toorkoman tribes. They also occupy a port or point in or connected with the Bay of Balkan, called by the Russians Krasnovodsk, and an island in the Bay of Mangushluck, still farther to the north. It is from some of these points that they have sent a military force against Khyvah, which, according to the latest accounts, had nearly perished from cold and fatigue. The greatest obstacle to the march of an army in these deserts is the want of water. The distance from Krasnovodsk to Khyvah is about 500 miles, in which, for several days' journey, no water is to be found. Fraser, in his account of the Persian empire, states his opinion that a Russian force might be set down on the eastern shore of the Caspian Sea, either at Balkan or at Mangushluck, "that, with common management, might not only capture, but retain possession of, Khyvah, and project and prepare for ulterior enterprises."[1] Russia has, as anticipated by Fraser, undertaken this expedition, which has in the mean time failed, as already stated, but whether from want of common management, or of a sufficient force, or from the difficulties of the enterprise, has not been clearly ascertained.

Russia supplies this extensive country, Khyvah, as well as Bockhara, with the greater portion of the European articles which its inhabitants require. [1] With both these places an intercourse is maintained by means of caravans, which proceed from Astracan by Orenburg. The route is long and dangerous, being about forty days' journey, and in many places exposed to the attacks of the Kirgeesh and Kuzaks, who inhabit the steppes north and north-west of Khyvah. The chief traffic is by sea to Mangushluck, where the Russian traders bring their goods, and are met by those from Khyvah. One great branch of trade consists in slaves captured from the surrounding countries in plundering expeditions, and Khyvah and Bockhara are the chief marts. The Toorkomans, the Yamoots, and even the tribes around Khyvah itself, make inroads into Persia, and carry off the cattle and the inhabitants, who are sold for slaves; and on the other side, the Kirgeesh and Kuzaks make prisoners of the Russians on their own frontiers, or when journeying in caravans, and carry them for sale to the great slave-markets in the east. Bockhara carries on a regular trade with Russia, Persia, and the east; for a more particular account of which, see the article Bukharia.

Several of those cities which have been mentioned, towards the east of this extensive region, are said to be rich and populous. But unless in those richer tracts which are interspersed through central Asia, and in the cities on the banks of rivers, the inhabitants generally retain their pastoral and migratory habits; and more especially as we proceed farther northwards among the Kirgeesh, who connect Independent Tartary with Russia, and have been already described. Everywhere fertile tracts are to be found; but the desert, the abode of the wandering tribes, greatly preponderates.

---

[1] See Appendix B, part ii.

Besides those tribes who still inhabit the country of Tartary, this pastoral population is spread over the southern provinces of Russia, which is inhabited by the Kalmucks and Baschkirs. The Kalmucks have been already described. They entirely resemble the other wandering tribes in their habits. They were formerly numbered among the most powerful tribes in Tartary, and they even boasted of the great conqueror Zingis as belonging to their nation. After various wanderings and misfortunes, the whole body settled, in 1723, on the banks of the Volga, from Tzaritzin to Astracan. They numbered 14,000 tents or families, and owned the supremacy of the czar. They could not, however, relinquish at once their predatory habits, in consequence of which they experienced the iron grasp of Russia, and numbers of them sought an asylum near the frontier of China, whither they emigrated about the year 1771. Those now inhabiting Russia still amount to about 40,000 or 50,000.

The Baschkirs inhabit the southern parts of the provinces of Orfa and Orenburg, with part of Tobolsk, between the rivers Belaia, Kama, Volga, and Oural. They were established in these countries from a very early period, and were instigated to repeated revolts, particularly in 1676, 1708, and 1735; and in 1771 they joined the standard of Pugatscheff. Their power was entirely broken in the course of their various conflicts with Russia; and after they were subdued, they experienced so much lenity from the Russian government that they are now numerous and prosperous. They retain all their Tartar habits, being entirely devoted to the rearing of cattle, and, so far, to the growing of such a supply of oats and barley as may serve them for winter food when milk fails them. They consist of 27,000 families, and are obliged to furnish their contingent to the Russian armies, being placed on the footing of Cossacs, mounted and equipped at their own expense.

II. Chinese Tartary. On the decay of the Tartar sway over central Asia, and the breaking up of their empire, a vast portion of territory fell under the dominion of China. It comprehends that extensive country which is situated between Hindustan and Asiatic Russia, bounded on the north by the great range of the Altai Mountains, and between the Eastern Ocean and the great range of the Beloor Taugh, which bounds Independent Tartary on the east. This space extends in its widest dimensions over seventy degrees of longitude and twenty of latitude. It is doubtful whether it includes or is bounded by Thibet on the south. It is in many parts mountainous and desert. The great desert of Shamo or Cobi stretches, nearly through its whole extent, over a space of nearly 2000 miles in breadth, and interposes between China and the Russian empire. This immense plain is in many places barren and destitute of water, but in other places is watered by rivulets and springs, or lakes, and affords pasturage to the hordes that wander over its desert parts, and is covered with herds of cattle. Our knowledge of this tract, especially of its western limits, is but imperfect, and is chiefly derived from the accounts of the early missionaries by whom it was visited. The most westerly district on the other side of the great mountain range of Beloor Taugh includes, according to the most recent accounts, the Mahommedan states of Kashgar and Yarkund, about 600 miles nearly east of Kokaun. The appearance of this country is in general more pleasing than that to the west, being better watered and more finely diversified, more verdant and better wooded, and differing both from the gravelly and rocky soil of Persia, Khorassan, Balk, and from the salt or sandy deserts of Khaurezm or Bockhara to the west. Kashgar is the more westerly of the two, and is situated in long. 76° 15′ 45″ E. and in lat. 39° 25′ N. It is a city of great celebrity, and of great commercial resort from the surrounding countries. It embraces a circuit of three miles, contains 10,000 houses, and is crowded with strangers. It was destroyed by Meerza Abubekr, the grandson of Timur, who having afterwards made it his residence, restored it to prosperity, and adorned it with many splendid edifices. Along with several of the neighbouring states, it has been under the dominion of China for the last seventy or eighty years. Yarkund, which by the road is 180 miles from Kashgar, and is placed in long. 78° 27′ 45″ E. lat. 38° 19′ N., enjoys a high degree of celebrity in that part of Asia, and is a rendezvous of merchants from India, Caubul, and Independent Tartary. The bazaar contains many handsome shops, which are chiefly occupied by the Chinese. The country which surrounds these cities is described as rich and fruitful, well watered and delightful, abounding in towns and villages, in rich cultivation, and especially in well-flavoured and delicious fruits.

The conquest of the country by the Chinese, as related by Fraser, took place about seventy or eighty years ago. About the year 1670 or 1680 the countries of Yarkund, Kashgar, and other neighbouring districts, were under the Moghuls or Mongoles, the descendants of Timur, from whom they were conquered by the Kalmucks, whose king resided at Eelah, and appointed governors over the other cities. A great plague having broken out among the Kalmucks, the Mongole lords, seeing the weakness of their rulers, rose in rebellion against them, and succeeded in regaining their lost power. But at this period they put to death an ambassador from China, who was despatched to their country by the emperor, on which he sent an army to avenge the insult, and after a severe conflict the country was subdued, and has ever since remained under the yoke, though they have still preserved their paternal seat, and live ostensibly under the government of their own princes. According to the accounts of travellers, the strictest order and an efficient police are maintained throughout the wide precincts of the Chinese authority; moderate duties are levied, trade is protected, and a single traveller may journey as securely as a large caravan.

That portion of Tartary which is to the west and northwest of China, is for the most part desert, or a naked and wide-extended plain, with occasional spots which are fertile and well watered, and afford pasture to the flocks of the wandering tribes of Mongoles, Kalkas, and Eluths. The origin of these tribes is but imperfectly known. The Mongoles are generally considered as having been the great disturbers of the world, whose reckless devastation seemed destined to destroy and obliterate arts and knowledge, and every vestige of civilized life. Being gradually broken into separate states, they were partly crushed by the rising power of Russia, and partly fell under the dominion of China. They are really, however, under the rule of the Chinese, though a small portion of them are within the dominions of Russia. These withdrew themselves from the Chinese dominion, and voluntarily put themselves under that of Russia; and this example would have been followed by other races, had not Russia engaged by a treaty not to give admittance to any more of these tribes. The Russian Mongoles inhabit the regions about the Selenga, in the government of Irkutsk, from the 122d to the 125th degree of longitude, and between the 50th and 53d degree of north latitude. The allegiance of those who are under the dominion of China is secured by a pension to their chiefs. They sometimes also engage in wars with each other, though these contests, when they rise to a certain height, are quelled by the Chinese. All these rude tribes are devoted to the religion of the Lamas.

The Mantchoo Tartars inhabit the most eastern extremity of Tartary, bordering on the Pacific, which, in consequence of having given a conquering dynasty to China, now forms a province of that empire. They resemble the Mongoles in person, but have a fairer complexion. They have adopted only to a limited extent the religion of Fo or Boodh, so universally established over the east of Asia; they have an ancient superstition of their own, to which they are greatly attached. They have also a peculiar language, which differs materially from that of the Chinese, Coreans, and Mongoles. It is rude in structure, but is said to be copious. Their country is in general mountainous and woody; the mountains are lofty, and the forests are of great depth. The cold is in proportion to the altitude; and though the latitude be only that of the south of France, the climate is cold, and the rivers begin to freeze in September. (F.)

TARTAS, a river of Asiatic Russia, in the government of Tobolsk, falls into the Om near Tartaskoi.

TARTASKOI, a small town of Asiatic Russia, in Tobolsk, situated at the junction of the Om and Tartas. It is forty miles west-south-west of Kainsk.

TARVEN or TARVIN, a town in the hundred of Eddisbury and county of Chester, four miles from the city of Chester, and 177 from London. The church is a well-built structure. The parish comprehends, besides the town, eleven small townships, whose population amounted in 1821 to 3486, and in 1831 to 3415; but the town contains only 1020.

TASAPAN, a small island in the Eastern Seas, near Junkseylon. Long. 98. 14. E. Lat. 8. 20. N.

TASHKUND, or TASHKENT, formerly a considerable city of Independent Tartary, situated on the Sihon or Jaxartes. It has suffered much from the devastations of war. It is 210 miles north of Samarcand. Long. 64. 48. E. Lat. 42. 40. N.

TASIEVA, a river of Asiatic Russia, in the province of Tobolsk, which falls into the Tchulim about twenty miles north-west of Tasicuskoi. The latter place is situated on this river, 820 miles of Tobolsk.

TASMAN'S HEAD, the most southern point of Bruny's Island, on the north-east coast of Van Diemen's Land.

TASMAN'S *Island*, a great peninsula connected with Van Diemen's Land by an isthmus 600 feet broad by about 1800 long. At the southern extremity is a small island, called Tasman's Island.

TASSISUDON, a city of Northern Hindustan, province of Bootan, of which it is the capital. It is the residence of the Deb rajah. It is situated in a highly cultivated valley, about three miles in length by one in breadth, intersected by the Tchintchieu river. The climate is esteemed exceedingly salubrious. The castle or palace is in the centre of the valley, built of stone of a quadrangular form, the walls thirty feet high, pierced with very small windows. The citadel consists of seven stories, each from fifteen to twenty feet high, and is a very lofty building. From the centre rises a square piece of masonry, which supports a canopy of copper richly gilt. The town is of considerable extent, and is populous. Its chief manufactures are brazen images, and paper made from the bark of a tree. Long. 89. 30. E. Lat. 27. 50. N.

TASSO, TORQUATO, one of the most celebrated of modern poets, was the son of Bernardo Tasso, himself eminent in the same path of literature. Bernardo, a native of Bergamo, noble but poor, published in 1560 his chivalrous poem of the Amadigi, which forms the link between the wild and half-burlesque school in which Ariosto was the chief, and the serious epic given to Italy by his own son.

Torquato was born in 1544, at the beautifully situated town of Sorrento, on the southern shore of the Bay of Naples; but, his father having been involved in the misfortunes and exile of a distinguished patron, the son's education was conducted in the north. At Padua, when he had scarcely completed his eighteenth year, he published his romantic poem called Rinaldo, which, aided by other compositions, soon spread his fame over the peninsula, and introduced him into the service of the house of Este, princes of Ferrara. His next work of importance was the Aminta, a pastoral drama, in which, although having no claim to rank as the inventor of that faulty species of poetry, he exhibited it in a height of excellence neither attained before nor since. But, in the midst of studies, minor compositions, and travels which carried him as far as Paris, his mind was mainly occupied in elaborating his great work, the "Gierusalemme Liberata," which he had planned and partly executed before leaving the university. Though the youthful sketch is still extant, the work was afterwards rewritten, and did not reach its close till 1575. The poet, now more than thirty years old, had already displayed those infirmities of character which made him, during the remainder of his life, the helpless victim of envious enemies, or of mean and heartless patrons. The tale which Goethe and Byron have made the theme of poetical invention, represents Tasso as the lover of Leonora d'Este, or, according to some biographers, of Lucretia her sister; but the story is neither sufficiently vouched, nor in itself either probable or consistent; and the real cause of the persecution to which he was subjected remains, after all investigations, as obscure as ever. We know, however, enough to show that his mind was but ill qualified to stand the shock and tumult of the world. That exquisite sensibility which reigns in his poetry was never dormant in any action of his life: deficient in moral courage, and acutely sensitive in taste, he hesitated for years to give his great poem to the public; his imagination, overwrought and undisciplined, filled him with exaggerated suspicions of all who were around him, and superstitious terrors completed his misery. He surrendered himself to the Inquisition, confessing, as heretical doubts, what the inquisitors had sense enough to consider as illusions of hypochondria; and, after an unlucky quarrel had brought on him a temporary imprisonment at Ferrara, he fled secretly from that city in 1577, and, crossing the central Appenines by unfrequented paths, sought refuge with his sister at Sorrento. For a year and a half after this period he wandered through Italy, alternately abandoning himself to fanciful despondence, and arousing his mind to the composition of some of his minor works. In 1579, returning to Ferrara for the second time since his flight, he was treated with neglect by the duke and his sisters, and insulted by the retainers of the court: he broke out, it is said, into violent reproaches against his alienated patrons; and, seized by order of the Duke Alfonso, he was immured in the hospital of Sant' Anna, a public madhouse. In this prison he remained more than seven years, receiving at one time permission to see his friends, and even to pay visits in the city, but treated during the greater part of the period with all the severities which in those days fell to the lot of ordinary maniacs. In the earlier years of his imprisonment, his mind seems to have gathered, from solitude and reflection, a strength of resolution which it had not before possessed, while his literary genius was undecayed and constantly active; but at length the horrors of his situation increased his constitutional tendency to mental disease, and there is little ground for doubting that, in the later period of his confinement, he laboured under a partial alienation of reason.

At length, however, the solicitation of powerful friends procured his release, which took place in 1586; and, although his after years present us with several stories of new misfortune and neglect, he found some patrons both kind

Tasso.

Tassoni || Taste.

and judicious. His Jerusalem Delivered had been published repeatedly during his imprisonment, in spite of his earnest remonstrances; and now, weaned alike from chivalrous enthusiasm and from the wish to flatter princes, he rewrote the whole poem, and published it anew at Rome in 1562, under the title of the "Gierusalemme Conquistata." In this altered shape the work was a religious allegory, and the Ferrarese princes were never named in it; but the original editions of the poem have kept their place in general favour, and the alteration is universally and not unjustly neglected. Except the tragedy of Torrismondo, all his other extensive compositions after his release were of a devotional cast. In the spring of 1595, while preparations were making for conferring on him the honours of that triumphal coronation in the Roman capitol, which had been invented in favour of Petrarca, he felt that his end was approaching, and retired to the convent of Saint Onofrio on the brow of the Janiculan Mount. He there expired placidly, having just completed his fifty-first year; and his body still lies beneath the pavement of the little church.

Tasso's works are very numerous, both in prose and verse; and recent examinations of libraries, both in Italy and France, especially that of Alfieri, now preserved at Montpellier, have added to the list many pieces, though without throwing any decisive light on the mysterious portions of his history. One of the most curious of the discoveries is a "Discorso intorno alla Sedizione nata nel regno di Francia," which was published in an Italian periodical in 1817. It was written during his residence of twelve months at Paris, and is a bigoted argument for the use of extreme severities against the Huguenots. This performance, with other treatises and letters, was reprinted by the Abate Mazzuchelli in 1822. Rosini's edition of the poet's works contains a volume exclusively devoted to letters and poems not previously published; and several separate collections have appeared, the most important being the "Trattato della Dignità ed altri Scritti," by Gazzera (Turin, 1838), and the "Manoscritti inediti" of Count Alberti (Lucca, 1837–8).

Tasso's prose dialogues and moral treatises, and his minor works in general, have scarcely received, even from his own countrymen, that attention which they fairly deserve; and Monti had some reason for declaring, that the poet's shade has been appeased but in part for the insults offered to him in his lifetime by Salviati and the other academicians of the Crusca. Many of his lyrics are exceedingly beautiful, and none of them more so than those gems which stand as choruses in the Torrismondo, atoning by their pathetic sweetness for a bad plot and a want of all dramatic vigour in the tragedy itself. But the Jerusalem Delivered will always continue to be its author's title to immortality; and, whatever its faults may be, there are assuredly no two epics of modern times that deserve to be placed above it. Regarded in comparison with other chivalrous poems of the fifteenth and sixteenth centuries in Italy, it distinguishes itself by two prominent features; its perfect regularity and simplicity of plan, and its lofty and single seriousness of temper. No preceding poem in the language had both these qualities; and Ariosto's, the masterpiece of the series, and in some respects the masterpiece of modern Italian literature, was possessed of neither. The completeness of finishing in the Gierusalemme is another excellence, in which it stands perhaps higher than any poetical work that has been composed since the days of Virgil: and the antithetical quibbles and plays upon words which descended from the Troubadours to Petrarca, from Petrarca to Tasso, and from Tasso (though not through him directly) to our own poets of the Elizabethan age, are faults more than balanced by the chivalrous sentiment, the picturesqueness of natural descriptions, the fanciful beauty of the supernatural machinery, and the tenderness which so often melts into irresistible pathos. We must not look, in that picture of the Crusades which Tasso has painted, for the stern and vigorous truth which such a mind as Shakspeare's would have incorporated in essential harmony with the poetical elements: we must not look even for that inferior kind of fidelity to historical features which gives so strong a charm to some poems of our own time; but we must view in it, with thankful admiration, a panorama of poetically romantic incident, and poetically chivalrous character, as delightful as any thing which genius has ever presented.[1] (B. L.)

TASSONI, Alessandro, who was born at Modena in 1565, and died in 1635, ranks as the best of those Italian writers who, in the seventeenth century, made the burlesque epic a remarkable branch of literature for their nation. His work of this class, "La Secchia Rapita," or the Rape of the Bucket, commemorates an incursion which, in the middle of the thirteenth century, the Modenese made into the town of Bologna, carrying off as a trophy the bucket of a public well. Much of the wit has perished with the remembrance of the persons satirized, and much more is too local to be relished or understood except in Italy; while the alternation of serious and lofty feeling with broad buffoonery, necessarily disgusts those who take their poetical creed from the hands of the French. But, in spite of Voltaire's contempt for the poem, it is one which must not be neglected by any systematic student of Italian literature. Another work equally characteristic is Tassoni's "Pensieri Diversi," a collection of ingenious and outrageous paradoxes, founded on a complete scepticism, real or pretended, as to the merits, not only of the great names in literature, but as to the uses of literature itself. A similar production, the "Considerazioni sopra il Petrarca," was an attack made, in the same spirit, upon the poetical idol of the author's countrymen.[2]

TASTE, a certain sensation excited in the mind by certain bodies, which are called *sapid*, applied to the tongue and palate, and moistened with saliva. This is the original and proper meaning of the word *taste;* but as the qualities of bodies which produce these sensations are unknown, they have obtained the names of the sensations themselves, by substituting the cause for the effect. Tastes have been divided into simple and compound, and philosophers have endeavoured to ascertain the number of each species. Attempts have likewise been made to determine from their tastes the effects of different substances on the human body, taken into the stomach as food or physic; but by stating the result of such inquiries, we should be more likely to mislead than to communicate useful information.

TASTE is likewise used in a figurative sense, to denote that faculty by which we perceive and judge of whatever is beautiful or sublime in the works of nature or of art. This faculty relishes some things, is disgusted with others, and to many is indifferent. It has also been called an internal *sense*, and by one philosopher a *reflex sense*, while others have considered it as the joint exertion of perception and judgment in some cases, and as a play of the imagination in others. To decide among these different opinions, it will be necessary to ascertain, if we can, what are the objects of this faculty. Scarlet, blue, green, and yellow, are all beautiful colours, and a cube and a sphere are beautiful figures; but it does not appear to us that a man could be said to have either a good or a bad taste for relishing the perception of a scarlet more than that of a yellow colour, or a spherical more than a cubical figure.

With respect to the objects of the external sense, we are so constituted by nature as to relish those kinds of food which are most wholesome, and such a taste is justly said to be sound and uncorrupted. It is at first in the highest perfection, for it depends not on culture of any kind, and is incapable of improvement. The reverse is the case with respect to internal taste. Every voice, it is true, unites in applauding elegance, simplicity, spirit in writing, and in blaming affectation, or a false brilliancy; but when critics descend to particulars, this seeming unanimity vanishes. Perhaps no man ever beheld the rising or setting sun without feeling emotions of pleasure; yet it is certain that the emotions of the clown are not the same, at least in degree, with those of the philosopher. Any beautiful object presented to the eye gives a pleasing sensation to the mind; and it appears to us that the clown feels nothing more than a mere sensation from the view of the rising sun, similar to what he would feel from a blazing heath. In poetry and painting the vulgar are always delighted with the melody of the verse, and the brilliancy of the colours, and think of nothing else as beauties.

---

[2] Walker's Memoirs of Alessandro Tassoni. Lond. 1815, 8vo.

If this be so, the pleasures which the vulgar derive from what are called objects of taste, are mere gratifications of the senses; but very different is the pleasure which the man of cultivated taste derives from the beauties of nature or of art. The mere sensation of the clown is followed by a train of ideas which hurries him beyond the object before him to its beneficent effects and its Almighty Creator. The nature of any person's taste, therefore, is generally determined from the character of his imagination and the soundness of his judgment. The simple perception of the object we find is insufficient to excite these emotions, unless it is accompanied with this operation of mind. Thus, when we feel the beauty or sublimity of natural scenery, we are conscious of a variety of images in our minds very different from those which the objects themselves can present to the eye.

If the mind is in such a state as to prevent this freedom of imagination, the emotion is not perceived. In so far as the beauties of nature or art affect the external senses, their effect is the same on every man who is in possession of these senses. But to a man in pain or in grief, the same scene will not produce any feeling of admiration, which at other times would have produced it in perfection.

There are many objects of taste which do not produce their full effect on the imagination, but through the medium of the judgment. The beauty of the Farnese Hercules is one kind of beauty, that of the gladiators in the palace of Chighi another, and that of the Apollo Belvidere a third. Each of these figures is acknowledged to be perfect in its kind; but, according to Sir Joshua Reynolds, the highest perfection of the human figure is not to be found but in that form which might be taken from them all, and which would partake of the activity of the gladiator, of the delicacy of the Apollo, and of the muscular strength of the Hercules. In this view the perfection of these statues consists in something which, being perceived by the eye, is referred by the understanding to what we know of the characters of Hercules, Apollo, and the gladiator, and which we suppose it was the intention of the statuaries to express. There are, besides, objects of which taste is sometimes said to judge, though they have little or no effect whatever on the imagination. A book of abstract science, written in a prolix and intricate style, may be said to be in a bad taste; and had Swift, in his clear and simple style, written an Essay on the Human Understanding, his work, supposing him to have been master of the subject, would undoubtedly have displayed more taste than Locke's, in which the terms are sometimes vague, and the periods encumbered. This is the case of Berkeley, who is admitted by all to have been a writer of good taste, though neither the Principles of Human Knowledge, nor the Minute Philosopher, is capable of affording pleasure, either to the senses or the imagination. His beauty consists merely in the perspicuity of his style, of which the understanding alone is the judge. The metaphysical writings of Dr Reid possess in an eminent degree the same beauty; and no man of true taste can read them without admiring the elegant simplicity of the composition as much as the strength of the reasoning, and feeling from the whole a pleasure which the inflated style of Shaftesbury cannot communicate.

If this be a just account of the pleasures of taste, that faculty cannot be properly considered as a mere internal sense, since to its enjoyments a well-stored fancy is necessary in some cases, and the reasoning power in all; and the poet and the painter who wish to excel in their respective professions, must not content themselves, the one with filling the ear of the reader with mellifluous sounds, and the other with dazzling or deceiving the eye of the spectator by the brilliancy of his colours, but both must strive for fame by captivating the imagination; while the architect who aspires to a similar celebrity must make the purpose of his ornaments obvious to every person capable of judging. The landscapes of Claude Lorrain, the music of Handel, and the poetry of Milton, excite feeble emotions in our minds, when our attention is confined to the qualities which they present to our senses, or when it is to such qualities of their composition that we turn our regard. It is then only we feel the sublimity or beauty of their productions, when our imaginations are kindled by their power, when we lose ourselves amid the number of images that pass before our minds, and when we waken at last from this play of fancy as from the charm of a romantic dream.

It is well observed by Sir Joshua Reynolds, that taste is sometimes praised in such terms by orators and poets, who call it inspiration, and a gift from heaven, that though a student by such praise may have his attention roused, and a desire excited of obtaining this gift, he is more likely to be deterred than encouraged in the pursuit of his object. "He examines his own mind, and perceives *there* nothing of that divine inspiration with which he is told so many others have been favoured. He never travelled to heaven to gather new ideas; and he finds himself possessed of no other qualifications than what mere common observation and a plain understanding are able to confer. Thus he becomes gloomy amidst the splendour of figurative declamation, and thinks it hopeless to pursue an object which he supposes out of the reach of human industry. But on this, as on many other occasions, we ought to distinguish how much is to be given to enthusiasm, and how much to common sense; taking care not to lose in terms of vague admiration that solidity and truth of principle upon which alone we can reason." Whoever possesses the ordinary powers of perception, sensibility of heart, good sense, and an imagination capable of being roused by the striking objects of nature and of art, may, without inspiration, become, by mere experience, a man of fine taste in the objects of which he aspires to be a critical judge.

This being the case, we may easily account for the variety of tastes which prevail among man, not only as individuals, but as nations. We have already mentioned the difference in one instance between the European taste and the African respecting female beauty; and we may now affirm, as we hope to prove our affirmation, that the one taste is equally correct with the other. The charms of female beauty exist not in the mere external form and colour considered by themselves (for then the inanimate statue of the Venus de' Medici would give more delight to the European beholder than the finest woman that ever lived); but we associate external beauty with sweetness of disposition, and with all the train of endearments which take place in the union of the sexes; and it is this association which delights the man of taste, as giving refinement to an appetite which itself is gross and sensual. A similar association must be formed in the breast of the African who has any taste; and as he never knew feminine softness, or any of the endearing qualities of the sex, but as united with thick lips, a flat nose, a black skin, and woolly hair, a sable beauty of that description must excite in his breast the same emotions that are excited in the breast of an European by the fair woman with Grecian features.

But is there not an ideal or perfect beauty of the human form? There certainly is, as of every other natural object; but it cannot be the same in Europe as in Africa, unless to a being who is acquainted with all the peculiarities of form, national and individual, that are to be found among the inhabitants of the whole earth. It has been supposed, and we think completely proved, by Mr Alison, one of our best writers on the philosophy of taste, that the sublimity or beauty of forms arises altogether from the associations which we connect with them, or the qualities of which they are expressive to us. The qualities expressed by the male and female forms are very different; and we would by no means think the woman beautiful who should have the form of the Farnese Hercules, or admire the shapes of the hero who should be formed like the Venus de' Medici; because the proportions of such a woman would indicate strength and intrepidity, where we wish to find only gentleness and delicacy; and the delicate form of the hero would indicate softness and effeminacy, where the opposite qualities only can be esteemed. As we associate with the female form many desirable qualities, every woman is esteemed more or less beautiful as her figure and features indicate a greater or smaller number of these qualities; and the same is the case with respect to the qualities which adorn the male character, and the form and features by which they are expressed. Upon comparing a number of human beings with one another, we find, that with respect to every feature and limb, there is one central form to which nature always tends, though she be continually deviating from it on the right hand and on the left. This form therefore is considered as the most perfect form of the species, and most expressive of the qualities for which that species is valued; but in Africa, the central form, with respect to the proportions of the human body and the features of the human face, is very different from what it is in Europe; and therefore the ideal or perfect beauty of the human form and features cannot be the same in both countries. No doubt, if a man could examine the limbs and features of every individual of the human race, he would discover one central form belonging to the whole, and be led to esteem it the standard of beauty; but as this is obviously impossible, the common idea or central form belonging to each great class of mankind must be esteemed the standard of beauty in that class, as indicating most completely the qualities for which individuals are esteemed. Thus there is a common form in childhood, and a common form in age; each of which is the more perfect as it is the more remote from peculiarities: but though age and childhood have something in common, we should not deem the child beautiful who was formed exactly like the most handsome man, nor the man handsome who was formed exactly like the most beautiful child. This doctrine is well illustrated by Sir Joshua Reynolds, who has applied it to every object esteemed beautiful in nature; and proved, that the superiority of Claude Lorrain over the landscape-painters of the Dutch and Flemish schools, arises chiefly from his having generalized his conceptions, and formed his pictures by compounding together the various draughts which he had previously made from various beautiful scenes and prospects. "On the whole," says he, "it seems to me that there is but one presiding principle which regulates and gives stability to every art. The works, whether of poets, painters, moralists, or historians, which are built upon general nature, live for ever; while those which depend for their existence on particular customs and habits, a particular view of nature, or the fluctuation of fashion, can only be coeval with that which first raised them from obscurity. All the individual objects which are exhibited to our view by nature, upon close examination will be found to have their blemishes and defects. The most beautiful forms have something about them like weakness, minuteness, or imperfection. But it is not every eye that perceives these blemishes. It must be an eye long used to the contemplation and comparison of these forms; which alone can discern what any set of objects of the same kind has in common, and what each wants in particular."

From these reasonings the same great artist concludes, that the man who is ambitious of the character of possessing a correct taste, ought to acquire a "habit of comparing and digesting his notions. He ought not to be wholly unacquainted with that part of philosophy which gives him an insight into human nature, and relates to the manners, characters, passions, and affections. He ought to know *something* concerning *mind*, as well as a great deal concerning the *body*, and the various external works of nature and of art; for it is only the power of distinguishing right from wrong that is properly denominated *taste*.

"Genius and taste, in the common acceptation, appear to be very nearly related; the difference lies only in this, that genius has superadded to it a habit or power of execution. Or we may say that taste, when this power is added, changes its name, and is called *genius*. They both, in the popular opinion, pretend to an entire exemption from the restraint of rules. It is supposed that their powers are intuitive; that under the name of *genius* great works are produced, and under the name of *taste* an exact judgment is given, without our knowing why, and without being under the least obligation to reason, precept, or experience.

"One can scarce state these opinions without exposing their absurdity; yet they are constantly in the mouths of men, and particularly of illiterate and affected connoisseurs. The natural appetite or taste of the human mind is for *truth;* whether that truth results from the real agreement or equality of original ideas among themselves, from the agreement of the representation of any object with the thing represented, or from the correspondence of the several parts of any arrangement with each other. It is the very same taste which relishes a demonstration in geometry, that is pleased with the resemblance of a picture to an original, and touched with the harmony of music.

"But besides *real*, there is also *apparent* truth, or opinion, or prejudice. With regard to real truth, when it is known, the taste which conforms to it is and must be uniform. With regard to the second sort of truth, which may be called *truth upon sufferance*, or *truth by courtesy*, it is not fixed, but variable. However, whilst these opinions and prejudices on which it is founded continue, they operate as truth; and the art whose office it is to please the mind as well as instruct it, must direct itself according to *opinion*, or it will not attain its end. In proportion as these prejudices are known to be generally diffused or long received, the taste which conforms to them approaches nearer to certainty, and to a sort of resemblance to real science, even where opinions are found to be no better than prejudices. And since they deserve, on account of their duration and extent, to be considered as really true, they become capable of no small degree of stability and determination by their permanent and uniform nature.

"Of the judgment which we make on the works of art, and the preference that we give to one class of art over another, if a reason be demanded, the question is perhaps evaded by answering, I judge from my taste; but it does not follow that a better answer cannot be given, though for common gazers this may be sufficient. Every man is not obliged to investigate the causes of his approbation or dislike. The arts would lie open for ever to caprice and casualty, if those who are to judge of their excellencies had no settled principles by which they are to regulate their decisions, and the merit or defect of performances were to be determined by unguided fancy. And indeed we may venture to assert, that whatever speculative knowledge is necessary to the artist, is equally and indispensably necessary to the critic and the connoisseur.

"The first idea that occurs in the consideration of what is fixed in art or in taste, is that presiding principle which we have already mentioned, the general idea of nature. The beginning, the middle, and the end of every thing that is valuable in taste, is comprised in the knowledge of what is truly nature; for whatever ideas are not conformable to those of nature or universal opinion, must be considered as more or less capricious; the idea of nature comprehending not only the forms which nature produces, but also the nature and internal fabric and organization, as I may call it, of the human mind and imagination. General ideas, beauty, or nature, are but different ways of expressing the same thing, whether we apply these terms to statues, poetry, or picture. Deformity is not nature, but an accidental deviation from her accustomed practice. This general idea therefore ought to be called *nature;* and nothing else, correctly speaking, has a right to that name. Hence it plainly appears, that as a work is conducted under the influence of general ideas, or partial, it is principally to be considered as the effect of a good or a bad taste."

Upon the whole, we may conclude that the real substance, as it may be called, of what goes under the name of *taste*, is fixed and established in the nature of things; that there are certain and regular causes by which the imagination and passions of men are affected; and that the knowledge of these causes is acquired by a laborious and diligent investigation of nature, and by the same slow progress as wisdom or knowledge of every kind, however instantaneous its operations may appear when thus acquired. A man of real taste is always a man of judgment in other respects; and those inventions which either disdain or shrink from reason, are generally more like the dreams of a distempered brain than the exalted enthusiasm of a sound and true genius. In the midst of the highest flights of fancy or imagination, reason ought to preside from first to last; and he who shall decide on the beauties of any one of the fine arts by an imaginary innate sense or feeling, will make as ridiculous an appearance as the connoisseur mentioned by Dr Moore, who praised as a work of the divine Raphael the wretched daubing by a Swiss copyist. The reader who wishes for further instruction in the philosophy of taste, may consult the article BEAUTY in this work; Dr Gerard's Essay on Taste, with the dissertations of Voltaire, D'Alembert, and Montesquieu; Alison's Essays on the Nature and Principles of Taste; and Sir Joshua Reynolds's Discourses delivered in the Royal Academy.

TATE, NAHUM, a poet and dramatist, the son of Dr Faithful Tate, was born in Dublin in the year 1652. He was educated in Trinity College, but did not betake himself to any profession. Upon the death of Shadwell in 1692, Tate succeeded him as poet laureat, and held that place until the reign of George I. whose first birth-day ode he lived to write, and executed it with unusual spirit. He died in the Mint in 1716. He was the author of ten dramatic performances, a great number of poems, and a version of the Psalms in conjunction with Dr Brady. A list of his plays may be found in the *Biographia Dramatica*, vol. i. p. 703.

TATIANUS, a Greek writer of the primitive church, was a native of Syria, and by profession a rhetorician. He was educated in paganism, but became a convert to Christianity, and a disciple of Justin Martyr, whom he attended at Rome. After the death of Justin, in the year 165, he adopted some very unsound opinions, and appeared as the author of a new sect, condemning marriage, enjoining abstinence from wine and animal food, and suffering only water to be used in the holy mysteries; whence his followers were called *Encratitæ* and *Hydroparastatæ*. From Rome he returned to the east, and opened a school in Mesopotamia; but when or where he died, we do not find recorded. His only work, "Oratio ad Græcos," was first printed at Zürich in 1546. An elaborate edition was published by William Worth, A. M. Oxon. 1700, 8vo.

TATIUS, ACHILLES, a Greek writer, is supposed by Fabricius to have flourished in the third or fourth century. His age seems however to be very uncertain. Suidas, who gives him the name of Achilles Statius, informs us that having originally been a Pagan, he was converted to Christianity, and at length became a bishop. He is best known as the author of a romance, in eight books, "De Leucippes et Clitophontis Amoribus." From the strain of the work, it may perhaps be supposed to have been written before his conversion. It first appeared in a Latin translation, executed by Annibal Cruceeius; a portion of which was printed at Lyon in 1544, and a complete edition at Basel in 1554. The Greek text was first committed to the press by Commelin [Heidelbergæ], 1601, 8vo. Another edition was published by Salmasius, Lugd. Bat. 1640, 12mo. This most learned individual, who was so eminently qualified for the task, is allowed to have executed it too hastily. After several intervening editions, followed that of Mitscherlich, which occupies the first volume of his *Scriptores Erotici Græci*. Biponti, 1792–4, 3 tom. 8vo. But the most elaborate and valuable edition that has yet appeared, was published by Jacobs, Lipsiæ, 1821, 8vo. This romance has been translated into English, and other modern languages. A composition of a very different nature has likewise been ascribed to Achilles Tatius; but it may perhaps be considered as doubtful whether they were both written by the same individual. This is a fragment of a treatise on the sphere, Περὶ Σφαίρας, and comprises an introduction to the Phænomena of Aratus. It was first published by Victorius, with his edition of Hipparchus, Florent. 1567, fol. The Greek text, accompanied with a Latin version, was inserted by Petavius in his Uranologion, Paris. 1630, fol.

TATISCHEVA, a fortress of Asiatic Russia, in the government of Oufa, on the Oural, twenty-eight miles west of Orenburg.

TATTA, a district of Hindustan, formerly contained within the great soubah of Moultan, but now comprehending nearly the delta of the Indus, which has been already described under the article SINDE. The country is intersected by the overflowing waters of the Indus, and where these do not reach, it is mostly sandy and barren. It is noted for a fine breed of camels, which are pastured on the barren plains. It produces a quantity of rice and salt, and the rivers abound with fish, which articles constitute the chief food of the inhabitants. It is now part of the dominions of the Ameers of Sinde, who have impoverished the country by their extortions.

TATTA, an ancient and celebrated city, and capital of the above district, situated near the banks of the Indus, about 130 miles by the course of the river from the sea. It was formerly a rich and commercial city, but is now greatly decayed, exhibiting, instead of the bustle and animation of its ancient trade, long streets of ruinous and uninhabited houses. The situation is in a valley formed by a range of low rocky hills, which, during the freshes of the Indus, is inundated; but being placed on an eminence, apparently formed by ancient ruins, Tatta has the appearance of an island when the adjacent flat is inundated by the rains. The streets are narrow and dirty; but the houses are superior to the low huts commonly seen in native towns. They are built on a peculiar plan. The walls are made hollow by small pieces of sticks, from eight to sixteen inches long, being nailed across each other, from the outer edges of a small frame of wood. They are placed diagonally, and thus form a strong frame on both sides, which is plastered over with mud or mortar, and afterwards has the appearance of a solid wall. They are frequently four stories high, with heavy flat roofs. Many of the better sort are built with brick and mortar on a frame of timber; and all, from the governor's house to the lowest hovel, have a sort of ventilators like chimneys, down which the wind blows cool and refreshing in the most sultry weather; at which time every aperture is shut to exclude the hot wind and the dust. The old English factory purchased by the company in 1751 still remains, and may be reckoned the best house in the place. To the southward, within the town, are the remains of an old fort.

The town was formerly defended by a strong brick wall with round towers. These are now heaps of ruins; and the mosques and pagodas that remain exhibit symptoms of rapid decay. The town is, however, estimated by Colonel Pottinger to be still six miles in circumference, exclusive of the ruins, which extend a great way on either side. No trace exists of the origin of this city, or by whom it was founded. The earliest mention of it occurs in the year 677, when it was fortified, and made some slight resistance to the victorious armies of the caliphs of Bagdad. Its site is supposed to be that of the Pattala of the Greeks; but the lower districts of Sinde have undergone such remarkable changes even within the memory of man, that all such conclusions rest on mere conjecture. The native princes of Sinde, when they shook off the Arab yoke, fixed on Tatta as their capital, which, from its favourable situation between India on the east, and Asia to the north and west, became a great commercial emporium, and one of the richest cities of Asia. No labour or expense was spared in beautifying the city with handsome buildings and the establishment of fine gardens; while the more important objects were attended to of affording facility to trade by cutting canals from the Indus, which runs four miles to the east of the town; through which goods were brought and landed from boats at the very doors of the merchants' houses. All traces of these ornamental improvements are now almost entirely obliterated, and the only aqueduct that yet remains is choked with rubbish, and is nothing superior to a common drain. The decline of this city may be dated from its subjection to the empire of Hindustan; still, at the time that it was visited by Nadir Shah on his return from Delhi, it was estimated to contain 40,000 weavers of calicoes and silk stuffs, with artisans of every other class and description to the number of 20,000 more; besides bankers, money-changers, shop-keepers, and sellers of grain, who were estimated at 60,000. The population has now dwindled down to less than 20,000; and the annual revenue of the city does not exceed one lac of rupees, or L.12,500, which is not equal to the monthly collections during the period of its former grandeur. The only manufactures now carried on in Tatta are a few white cloths, and coloured loongees, which are cloths for sashes, turbans, &c. of silk or cotton. The streets are deserted; the few shops that remain open are scarcely worthy of the name, and the whole bazaar exhibits a deplorable picture of poverty and depressed commerce. The chief exports are ghee, bdellium, potash, oil, raisins, saltpetre, aniseed, musk, chintzes, shawls from Shikarpoor, carpets, and a variety of drugs. The imports are cocoa-nuts, pepper, cardamoms, betel-nuts, nutmegs, cinnamon, silk raw and manufactured, cochineal, broad cloth, quicksilver, tin, iron, steel, copper, lead, black wood, sandal wood, and sandalwood oil. The Indus is in general shoal opposite to Tatta; and in consequence trading boats lie off a small village named Begurah, distant five miles, with generally two, but sometimes four fathoms of water, and the breadth of the river about one mile. The boats used here on the Indus are generally square at both ends, low forward, high abaft, flat-bottomed, and drawing only a few inches of water; they are either pushed along with poles, or dragged, and when the wind is fair sails are used. There are four routes from Tatta to Hyderabad, two by land, and two by water; the shortest of which may be estimated at fifty-three miles. The country around Tatta, with the exception of the hill of Mukulee, about three miles to the west, is a perfect level. These hills, as well as the plain, are covered with a thick jungle, principally of the tamarisk and a species of bastard myrtle. The heat, when Colonel Pottinger was at Tatta, was excessive, the thermometer ranging from 91° to 102°; but towards the middle of July the atmosphere was refreshed by copious rains, and by strong southerly gales, which rendered the air cooler towards the middle of July. The hill of Mukulee, already mentioned, is covered with a number of graves and mausoleums, the habitations of the dead, the only remaining melancholy memorials of ancient magnificence, greatly exceeding those of the living. The tomb of Mirza Eesa Toorkhan, which is supposed to have been erected in 1622, is uncommonly magnificent and well executed. It consists of a large building, eighty-five feet square, and two stories high, with a cupola seventy feet high, partly hid by two balconies, the fronts of which are supported by pillars. It is enclosed by a high wall, the stones of which are neatly engraved and inlaid. The whole is of a yellow freestone; and inside, under the centre of the dome, is a mound of black stone, on which are engraved the names of the inmates of this gloomy dwelling. Several tombs are built of the same kind of stone; and there are others highly ornamented with enamelled tiles of beautiful green, purple, and blue colours; but "the exquisite engraving," says Pottinger, "of chapters of the Koran on the stone door-frames, surpassed every thing else that we found worthy of observation in these sepulchres." On the southern side of the hill there is also dug out of the solid rock a very remarkable well, with a chamber all round it, about twelve feet below the surface, to which the descent is by spiral steps. The water of this well has a strong medicinal taste. On the banks of the Indus, seven miles above Tatta, is another hill covered with white mosques and tombs of deceased Mahommedans, some of the latter of considerable size. Travelling distance from Bombay 741 miles, from Calcutta 1602 miles.[1] (F.)

TATTERSHALL, an English market-town, in the hundred of Gartree and division of Lindsey, in the county of Lincoln, 127 miles from London and fourteen to the north-west of Boston. It is on the Bain, a river that is navigable to the Withan, into which it flows in its way to the sea. The church, which was formerly collegiate, is a very beautiful and spacious edifice, in the form of a cross; but has suffered from time, and from the outrages of the civil wars. The population amounted in 1831 to 599.

TATTOOING, or TATTOWING, an operation in use among the islanders in the South Sea, for marking their bodies with figures of various kinds, which they consider as ornamental. It is performed by puncturing the skin, and rubbing a black colour into the wounds. The instrument used somewhat resembles a comb, the teeth of which are repeatedly struck into the skin by means of a small mallet. It is very painful; but the children are forced by their relations to submit to it.

TAUDA, a river of Asiatic Russia, formed by the junction of the Sosva and the Losva, and which falls into the Tobol, four miles south of Tobolsk.

---

[1] Pottinger's Journey through Beloochistan and part of Persia. Rennell's Memoir of a Map of Hindustan. Hamilton's East Indian Gazetteer, &c.

TAUJEPOOR, a town of Hindustan, in the province of Bengal, district of Purneah, thirty-six miles east by north from the town of Purneah. Long. 88. 15. E. Lat. 25. 45. N.

TAULLAH Mhokee, a small village of Hindustan, in the province of Lahore, nine miles north of Nadone, the principal town of the Kaungrah country. It contains a temple highly esteemed by the credulous Hindus, who believe that a volcanic flame which issues from the side of a mountain in the neighbourhood is an emanation from the divinity. Long. 75. 45. E. Lat. 32. 5. N.

TAUMAGO, an island in the Pacific Ocean, discovered by Quiros in 1606, about twenty-four or twenty-five miles in circumference. Long. 169. 25. E. Lat. 10. S.

TAUNDA, a town of Hindustan, in the nabob of Oude's territories, situated on the south side of the Goggrah river, thirty-five miles south-east from Fyzabad. Long. 82. 38. E. Lat. 26. 33. N. It is celebrated for its manufacture of cotton cloths. This is the name of another town of Hindustan, in the province of Gujerat. Long. 74. 29. E. Lat. 22. 55. N.

TAUNTON, a large town of the hundred of its name, in the county of Somerset, 144 miles from Bristol. It is finely situated in the rich and fertile valley of Taunton-Dean, which is watered by the river Tone. It has also water communication by a canal with the river Parrett and the sea at Bridgewater. It is a very well built town, with a fine market-place, in which stand both the county and the town hall. There are two churches, and that of St James is a fine and large building, with a magnificent tower. It has numerous places of worship for the several sects of Protestant dissenters, and a chapel for the Catholics, who have also lately established a female convent. This is an ancient borough, but it lost its corporate rights by suffering the numbers to become so low, and not to have a quorum left to fill up the vacancies. It is now under the jurisdiction of the county magistrates, and returns two members to parliament. It was formerly a place for manufacturing cloth goods, but that trade has greatly declined. In the mean time the trade of throwing silk has been introduced, and gives employment to some of the population. Taunton is chiefly inhabited by families of moderate incomes, who are induced to settle there from its being pleasant, cheap, and healthy. There are markets on Wednesday and on Saturday, well supplied. The inhabitants amounted in 1801 to 5794, in 1811 to 6997, in 1821 to 8534, and in 1831 to 11,139.

TAUNUS Mountains, a district of Germany, in the dominion of the prince of Nassau. In Germany this range of mountains was long denominated the Heights of Homburg, and belonged to the duchy of Hesse-Darmstadt before it came to the house of Nassau, as a portion of the duchy of Katzerellenbogen. It lies between the Rhine and the Maine, the former being its western, and the latter its southern boundary. The face of the country is very irregular; it consists almost wholly of hills and valleys, especially in the eastern part, where streams and wood present themselves to the traveller in great variety. The most lofty points of these hills are the Gros-feld-berg, 2605 feet, and the Altkonigberge, 2450 feet, in height. In these mountains are the mineral springs which form the great source of the wealth of the duchy. The chief of them are at Ems, Schwalbach, Schlangenbad, and Soden. There is another spring at Selzers, whose water is not drunk at the well, but put into stone bottles, of which about 1,500,000 are annually distributed over Europe. These mountains contain abundance of iron ore, which is worked extensively by the charcoal made from the neighbouring hills. There are also some mines of lead and of silver, but not productive to any great extent. Except the making of stone bottles and ironware, the chief occupation is agriculture, and even on the table-land, lofty as it is, good crops of rye are produced. The only river among these mountains is the Lahn, a romantic stream falling into the Rhine below the town of Ems, and navigable by boats in wet weather as high up the valley as Weilbourg. Over this stream, at Nassau, an iron suspension bridge has been constructed, being the first erection of that kind in Germany.

TAUREE, a town of the province of Bengal, district of Monghir, ninety-two miles north-north-west from Moorshedabad. Long. 86. 50. E. Lat. 24. 31. N.

TAURIA, a province of Russia in Europe, the most southern part of that empire. The peninsula known to the ancients as *Chersonesus Taurica*, and now known by the Tartar name of Crem, or Crimea, forms the better portion of the province. The northern portion is the Steppes of the Nogay Tartars. The whole extent is 44,903 square miles. The southern part is a beautiful country, with lofty hills and delightful valleys between, which, when cultivated, are extremely fertile; and the climate resembles that of the best part of Greece. The northern part, or Steppes, is fertile, but during a portion of the year is burnt up, and exhibits a bare sandy plain. After rain the grass springs up with intense rapidity, and the wheat that is sown yields very abundant crops. The breeding of cattle is, however, the chief pursuit, and especially that of horses, which are very numerous; and those crossed by the Arab race are of great value. The cows and sheep are numerous, but the wool of the latter is very coarse. When the Russians obtained possession of this country, it was much more populous than it has been since, many of the Mahommedan inhabitants having forsaken it. At present it contains about 370,000 inhabitants. They are of various religions, as well as races, some fixed, but more migratory. It comprehends a climate from 44° 30′ to 47° 41′ north latitude, and consequently is adapted to produce the fruits and other vegetables of the warm regions, and when well peopled will become a most important portion of the Russian empire.

TAURIS. See Tabriz.

TAURUS, a celebrated range of mountains, so called by the ancients, and which were said to extend from the Grecian Archipelago to the extremities of Asia. By some they were thought to take their rise in Caria and Pamphylia; and by others among the more modern geographers, on the coast of Cilicia, not far from Scanderoon. The range intersects Asia Minor from east to west, and advancing in a north-east direction, interrupts the course of the Euphrates, and spreads itself over the kingdom of Armenia, where it unites itself with Mount Caucasus. It then diverges into Persia with a variety of branches, of which the most conspicuous is that named Mount Zagros by the ancients. This long and lofty range formerly divided Media from Assyria, and now forms the boundary of the Persian and Turkish empires. It runs parallel with the river Tigris and the Persian Gulf, and almost entirely disappears in the vicinity of Gombroon; seems once more to rise in the southern districts of Kerman, and following an easterly course through the centre of Mekran and Beloochistan, is entirely lost in the deserts of Sinde.

TAVAI Poenammoo, an island in the South Pacific Ocean, being the more southerly of the two which form New Zealand, and separated from the northern island by a channel called Cook's Straits, that celebrated navigator having sailed round them both in the year 1769. The island is about 500 miles in length from south-west to north-east and from 55 to 140 broad. Long. 184. 45. to 193. 18. W. Lat. 40. 36. to 47. 20. S. See Zealand, New.

TAVERNIER, John Baptist, a French traveller, was born in 1605. In the course of forty years he travelled six times to Turkey, Persia, and the East Indies, and visited all the countries in Europe, travelling mostly on foot. His travels have been frequently reprinted in six volumes, 12mo.

He died, on his seventh journey to the east, at Moscow, in 1686.

TAVISTOCK, an English market and borough town in the hundred of the same name, in the county of Devon, 206 miles from London and fourteen from Plymouth. It stands at the foot of the mountains called the Forest of Dartmoor, by which it is well sheltered from northerly and easterly winds, and the situation is remarkably salubrious. The river Tavy passes by the town, but not being navigable, a canal has been constructed from Tavistock to the Tamar at Morwelham quay. A tunnel passes through a solid rock for more than 2500 feet, and not far from it is an aqueduct across a vale of considerable extent. The canal serves for the transport of copper ores and lead from the mines, and slates from the quarries, in the district, and brings coals, stone, timber, and other goods, to the town. This is an ancient town, formerly belonging to the abbey, some remains of which still exist, which was granted by Henry the Eighth, at the Reformation, to the family of the Russells. The refectory of the monks has been converted into a dissenting place of worship. A very handsome gatehouse, and two towers, both opening into the vicar's garden, are still standing. The trade of the town formerly consisted for the most part in the manufacture of serges and coarse woollen cloth, but these have for some years been on the decline. The mining business in the vicinity gives occupation to many of the inhabitants, and the smelting of tin and a great iron foundery afford some employment to others. The church is a large ancient building, and, besides some curious monuments, has a stone coffin, in which are preserved some human bones of gigantic size, attributed by tradition to a Saxon giant named Adulph. The greater part of the town belongs to the duke of Bedford. It returns two members to parliament. There is a well-supplied market on Saturday. The inhabitants amounted in 1801 to 3420, in 1811 to 4723, in 1821 to 5483, and in 1831 to 5602.

TAVOY, a town and district of the province of Pegu, in the Birman empire, which so late as the year 1753 was the seat of an independent principality. The town is advantageously situated on the eastern side of a fine bay, formed by an extensive island of the same name. Tavoy formerly belonged to the king of Siam, but was taken by the Birmans in 1785. It was besieged without success by the Siamese the following year, and remained in possession of the conquerors till 1790, when it was surrendered for a bribe to the Siamese troops. It was retaken by the Birmans in 1792, and was confirmed to them by the treaty of peace in 1793. Long. 98. 20. E. Lat. 13. 20. N.

TAWALLY ISLE, one of the Gilolo Islands, in the Eastern Seas. It is thirty-five miles long from north to south, and six in average breadth. Long. 127. 14. E. Lat. 0. 21. S.

TAWEETAWEE, the chief of a cluster of islands, fifty-six in number, composing part of the Sooloo archipelago. It has few inhabitants. The other islands are of various sizes; and some are merely rocky islets.

TAWING, the art of dressing skins in white, so as to render them fit for divers manufactures, particularly gloves, &c. All skins may be tawed; but those chiefly used for this purpose are lamb, sheep, kid, and goat skins. The method of tawing is this. The skins having been cleared of wool or hair by means of lime, are laid in a large vat of wood or stone, set on the ground, full of water, in which quicklime has been slaked; where they are allowed to lie a month or six weeks, according as the weather is more or less hot, or as the skins are required to be more or less soft and pliant. While they are in the vat, the water and lime are changed twice, and the skins are taken out and put in again every day; and when they are taken out for the last time, they are laid all night to soak in a running water, that the greatest part of the lime may be removed; and in the morning are laid together by sixes one upon another, upon a wooden leg, and are scraped stoutly one after another, to get the flesh off from the fleshy side, with a cutting two-handled instrument called a knife; and then they cut off the legs and other superfluous parts about the extremes. They are afterwards laid in a vat or pit with a little water, where they are fulled with wooden pestles for the space of a quarter of an hour; and then the vat is filled up with water, with which they are rinsed.

In the next place, they are thrown on a clean pavement to drain, and afterwards cast into a fresh pit of water, out of which they rinse them well; and they are again laid on the wooden leg, six at a time, with the hair side outermost: after which they rub a kind of whetstone very briskly, to soften and fit them to receive four or five more preparations, given them on the leg both on the flesh side and hair side, with the knife, after the manner above mentioned. After this they are put into a pit of water and wheaten bran, and stirred about in it with wooden poles till the bran is perceived to stick to them, and then they are left. As they rise of themselves to the top of the water by a kind of fermentation, they are plunged down again to the bottom; and at the same time fire is set to the liquor, which burns as easily as if it were brandy, but goes out the moment the skins are all covered. They repeat this operation as often as the skins rise above the water; and when they have done with rising they take them out, lay them on the wooden leg, the fleshy side outwards, and pass the knife over them to scrape off the bran.

Having thus cleared them of the bran, they lay the skins in a large basket, and load them with huge stones to promote the draining; and when they are drained sufficiently, they give them their feeding, which is performed after the manner following. For 100 of large sheep-skins, and for smaller in proportion, they take eight pounds of alum and three of sea-salt, and melt the whole with water in a vessel over the fire, pouring the solution out, while yet lukewarm, into a kind of trough, in which are twenty pounds of the finest wheat-flour, with the yolks of eight dozen of eggs; of all which is formed a kind of paste, a little thicker than children's pap. This, when prepared, is put into another vessel to be used in the following manner. They pour a quantity of hot water into the trough in which the paste was made, mixing two spoonfuls of the paste with it; to do which they use a wooden spoon that contains just as much as is required for a dozen of skins; and when the whole is well diluted, two dozen of the skins are plunged into it; but they take care that the water be not too hot, which would spoil the paste and burn the skins. After they have lain some time in the trough, they are taken out, one after another, with the hand, and are stretched out. This they do twice; and after they have given them all their paste, they put them into tubs, and there full them afresh with wooden pestles. They then put them into a vat, where they are suffered to lie for five or six days, or more; after which they take them out in fair weather, and hang them to dry on cords or racks; and the quicker they are dried the better; for if they are too long in drying the salt and alum within them are apt to make them rise in a grain, which is an essential fault in this kind of dressing.

When the skins are dry, they are made up into bundles, and just dipt in fair water, and taken out and drained: they are then thrown into an empty tub; and after having lain some time are taken out and trampled under foot. They then draw them over a flat iron instrument, the top of which is round like a battledore, and the bottom fixed into a wooden block, to stretch and open them; and having been opened, they are hung in the air upon cords to dry; and being dry, they are opened a second time, by passing them again over the same instrument. In the last place, they are laid on a table, pulled out, and laid smooth, and are then fit for sale.

printed books as contained his marginal annotations. Of this clause the book-collecting physician is said to have taken a very illiberal advantage, and to have enforced it with the utmost rigour, so as to include a very large number of books which the testator had intended to form a part of his legacy to Shrewsbury school. (x.)

TAYLOR'S Isles, three small islands on the north coast of New Holland, between Thistle Island and the shore, from which they are about two miles distant.

TAYMING, a city of China, of the first rank, in Pe-che-lee, in a fertile country, 232 miles south-south-west of Pekin. Long. 114. 49. E. Lat. 36. 20. N.

TAZE, a river of Asiatic Russia, which rises from two lakes in the government of Tobolsk, and after a considerable course from south to north, falls into the Tazovskaia Gulf, in the Frozen Ocean. Long. 80. 14. E. Lat. 67. 35. N.

TAZLA, a lake of Asiatic Turkey, thirty-six miles long and two broad, thirty miles north of Kognieh.

TAZOVSKAIA, a gulf or bay in the Obskaia Gulf, about 140 miles in length and three in breadth, formed by the waters of several rivers in Siberia. Long. 76. to 80. E. Lat. 67. 40. to 69. N.

TCHABISCHI, a town of Russia, in the government of Irkoutsk on the Amur, forty miles north-north-east of Stretensk.

TCHADOBETZ, a river of Asiatic Russia, which flows through the governments of Irkoutsk and Tomsk, and after a course of 250 miles falls into the Tunguska near Yeniseisk.

TCHAGANE, a river of Asiatic Russia, which rises in the country of the Kirghises, and after a course of 100 miles falls into the Derkoul, when their united waters flow into the Oural.

TCHANG-TCHA, a city of China, of the first rank, in Houquang, on the Heng river, 742 miles south of Pekin. Long. 112. 25. E. Lat. 28. 11. N.

TCHANG-TCHEOU, a city of China, of the first rank, in Fokien, the most southerly of the province. It is situated on a river, and carries on a considerable trade. It is 950 miles south of Pekin. Long. 117. 34. E. Lat. 24. 32. N. This is the name of another city, two leagues in circumference, which is the seat of a very extensive trade, and contains 200,000 inhabitants. It is 525 miles south-south-east of Pekin. Long. 119. 29. E. Lat. 31. 50. N.

TCHANG-TE, a large city of China, of the first rank, in Houquang. It is situated on a river near the great lake Tong-Ting, and is 717 miles south-south-west of Pekin. Long. 111. 2. E. Lat. 29. 2. N.

TCHAN-TE, one of the most northern cities of the province of China, in Honan. It is 255 miles south-south-west of Pekin. Long. 114. 0. E. Lat. 36. 6. N.

TCHANY, a large lake of Asiatic Russia, situated in the Barabinski steppe, between the Ob and the Irtysch. It is about sixty-five miles long and thirty broad, and is 100 miles west-north-west of Kolivan.

TCHAOKING, a city of China, of the first rank, in Quang-tong, situated at the confluence of three rivers, one of which communicates with Canton. It is 1062 miles south-south-west of Pekin. Long. 111. 44. E. Lat. 23. 3. N.

TCHE-KIANG, a province of China, bounded on the north and north-west by Kiang-nan, on the east by the sea, on the south by Fokien, and on the south-west by Kiang-see; about 200 miles in length from north to south, and from 120 to 180 broad. This is one of the most considerable provinces in the empire, and contains, according to Sir George Staunton, 21 millions of inhabitants.

TCHELAO, a town of Persia, in the province of Khorassan. Near it is the well-known defile in the mountains, called by the eastern writers, Hell, from the difficulty of the passage.

TCHELIABINSK, a town of Asiatic Russia, in the government of Orenburg. It stands on the river Masse, which falls into the Icette; and is one of the most important fortresses upon this frontier. It contains two churches and 500 houses, and is 118 miles east of Oufa. Long. 62. 4. E. Lat. 54. 50. N.

TCHENG-TE, an island in the Eastern Seas, near the south coast of Corea, about ten miles long and six broad. Long. 128. 37. E. Lat. 34. 20. N.

TCHEOU-CHAN, or Chu-san, an island in the Chinese Sea, near the west coast of China, belonging to the province of Tche-kiang, about twenty-four miles long, and from four to ten broad.

TCHEPETKINA, a river of Asiatic Russia, which runs into the Kolima, 88 miles north of Verchnei Kovimskoi. Long. 148. 14. E. Lat. 67. 35. N.

TCHERNIKEH, a town of Asia Minor, in the government of Sivas, anciently a city of Pontus. It is twenty-four miles north of Amasia. Long. 36. 38. E. Lat. 40. 26. N.

TCHETKINA, one of the Fox Islands, in the North Pacific Ocean. Long. 184. 44. E. Lat. 53. 30. N.

TCHING-KIANG, a city of China, of the first rank, in Kiang-nan, on the south side of the river Yang-tse. It is finely situated for commerce, and is the key of the empire towards the sea. The walls are thirty feet high, and the streets are paved with marble.

TCHING-TCHEOU, a city of China, of the first rank, in Houquang. It is situated on an angle made by two rivers, and is 765 miles south-south-west of Pekin. Long. 109. 40. E. Lat. 28. 23. N.

TCHING-TING, a city of China, of the first rank, in Pe-che-lee, about four miles in circumference. It is 137 miles south-south-west of Pekin. Long. 114. 20. E. Lat. 39. 9. N.

TCHING-TOU, a city of China, of the first rank, in Sechuen. It was formerly one of the finest cities in the empire, but was almost entirely destroyed in the civil wars in 1646, which preceded the last Tartar invasion. It is 810 miles south-west of Pekin. Long. 103. 44. E. Lat. 30. 40. N.

TCHONG-KING, a city of China, of the first rank, in in Sechuen, and one of the most commercial cities of the province. It is 750 miles south-west of Pekin. Long. 106. 19. E. Lat. 29. 42. N.

TCHORS, a village of Persia, in the province of Azerbijan, inhabited by the Kurds subject to Persia. It is 78 miles west-north-west of Tauris.

TCHOUKTCHES, a people inhabiting the peninsula which forms the north-east extremity of Asiatic Russia; bounded on the one side by the Frozen Ocean, and on the other by the Gulf of Anadir. They live by hunting and fishing.

TCHUKOTSKOIE, a cape in the country of the Tchouktches, forming the north-eastern extremity of Asia.

TCINAN, a large and populous city of China, of the first rank, in the province of Shang-tung. It is 235 miles south of Pekin. Long. 116. 46. E. Lat. 36. 46. N.

TCIN-TCHEOU, a city of China, of the first rank, in Shang-tung, 230 miles south-south-east of Pekin. Long. 118. 20. E. Lat. 36. 46. N.

TCITCICAR Hotun, a town of Chinese Tartary, capital of a province in the country of the Mantchoos; the usual residence of a Tartar general. It is 355 miles north-east of Pekin. Long. 123. 30. E. Lat. 47. 25. N.

TEA is produced by different species of thea or camellia. It has generally been imagined that China was the only country where the tea-plant would grow, or where it could be cultivated and manufactured. Recent investigations, however, have dissipated this delusion. It has been found that the Japanese and the Brazilians as well as the Chinese have cultivated tea with success; and, what is of the utmost importance to Britain, it has lately been discovered beyond all doubt that the tea-shrub is indigenous in our Indian territories of Upper Assam, being found there through an extent of country of one month's march from Suddya and Beesa to the Chinese frontier province of Yunnam. For this most important and valuable discovery we are chiefly indebted to the indefatigable researches of Captain Jenkins, Lieutenant Charlton, and C. A. Bruce, Esq.

Mr Abel the botanist, who accompanied Lord Amherst upon his embassy to China, says,—

> " The green-tea districts in the province of Keang-nan are embraced between the 29th and 31st degrees of north latitude, and are situated on the north-western base of a ridge of mountains which divide the provinces of Keang-nan and Keang-see.
>
> " The black-tea districts in the province of Fo Kien are contained between the 27th and 28th degrees of north latitude, and are situated on the S. E. declivities of a ridge of mountains, dividing the province of Fo Kien from that of Keang-nan. Thus the whole range of the great districts of China from which Europe is supplied with tea, from the highest to the lowest degree of latitude, is from 31° to 27°. According to the missionaries, the tea-plant thrives in the more northern provinces, as at Pekin ; and from Kempfer, it would appear that it is cultivated in Japan as far as 45° north.
>
> " From every account given of the tea-plant, it succeeds best on the sides of mountains, where there can be little accumulation of vegetable mould ; our opportunities of seeing its cultivation were few, but were all in favour of this conclusion. The plantations were always at some elevation above the plains, in a kind of gravelly soil, formed in some places by disintegrated sandstone, and in others by the debris of primitive rocks. A large and flourishing plantation of all the varieties of the tea-plant (brought together by Mr Bell, the principal tea-inspector at Canton) is situated on an island close to Macao, in a loose, gravelly soil, formed by the disintegration of large grained granite. Judging from the specimens collected in our route through the province of Keang-nan, whence the green tea is provided, the rocks consist chiefly of sandstone, schistus, and granite. As to the precise nature of the rocks of the black-tea country in the province of Fo Kien, I have no exact information ; but as the great ridge, separating that province from Keang-see, is a continuation of one separating the latter from Canton, it is perhaps legitimate to conclude, that their constituent rocks are the same, and that the hills and soil on the eastern side are the same as we found them on the western side of the ridge, and that they are covered by a soil like that in which the camellia flourishes ; the vegetation chiefly consists of the same kind of plants. But the success of the American plantations proves that the tea-plant will flourish within the tropics ; and that it will grow vigorously within them, is proved by the fine plants in Sir H. Low's plantations at St Helena."

In China the hills on which tea is cultivated are not high, and the plantations where the soil is favourable extend over their entire face from the summit to the base. The difference of the temperature from that of the adjacent plains is scarcely perceptible ; but it is on the nature of the soil that the quality of the tea principally depends. Rain falls in March and April in moderate showers, and the atmosphere is extremely moist ; the finest leaves appear at this time, and are plucked early in April. In May the rain is very heavy, and the leaves begin to be of inferior quality.

The seeds are put into the ground towards the end of February, or early in March, and spring up almost immediately. The plants stand about three feet and a half distant from each other. They require scarcely any manure ; only at first a little mud or thick mucilage is applied to each plant. No other tree is planted among the tea-shrubs, but they are propped up with bamboos. Seedlings of one year's growth, if too thick, are thinned ; but their leaves are not used for two years. After this the leaves of every plant are gathered three times a year, young and old indiscriminately. The gatherers and the driers of the tea are quite distinct classes, the wages of the former being from fivepence to sevenpence of our money per day, while some of the latter receive as much as 200 dollars for the season. A man can gather about fifteen pounds of tea-leaves per day ; the price of labour in India being only from twopence to threepence per day. Should the plantations which have been commenced in that quarter succeed, the teas of Assam should be procured at one half the cost of those of China.

The districts of India in which the native tea has been discovered, lie between 94° and 96° of east longitude, and 26° and 28° of north latitude. Muttuck, which is to the south of the Delree river, is a country that abounds in tea, and it might be made one extensive beautiful tea-garden ; and were the hills and valleys of Assam all cultivated, they would be sufficient to supply the immense demand of Britain.

The tea-plant, which is an evergreen, grows in China to the height of from three to six feet, but seldom more than three. The plants which have been discovered in Assam are much taller. Mr Bruce relates, that in going over one of the low hills behind Jeypore, he came upon a tea-tract which must have been two or three miles in length, on which the wild tea trees were as thick as they could grow ; and one of them he found to be three feet in circumference and about sixty feet in height, but this was an extraordinary instance : and he is of opinion that the effect of regularly cultivating the plants in tea-gardens, transplanting and trimming them, and plucking off all the young leaves from month to month as soon as they appear, will tend to stunt and shorten the growth, so that they will not generally rise higher than in China.

The tea-plants in Assam have in general been found to thrive best near small rivers and pools of water, and in those places where, after heavy falls of rain, quantities of water have accumulated and cut out for themselves numerous small channels. In Assam the wild tea-plants are never met with growing in the sun, but invariably under the shade in thick woods or jungle.

The following extracts are from Mr Bruce's Report on the Tea Plantations in Assam.

> " With respect to the tea-plant being most productive on high or low ground, I cannot well say, as all our tracts are on the plains ; but from what little I have seen of the hill tracts, I should suppose they were not more productive. In China, the hill tracts produce the *best* teas, and they may do the same here. Almost all my tracts on the plains are nearly on the same level, I should think. *Nudwa*, perhaps, is a little higher than *Tingri*, and *Tingri* a little higher than *Kahung* ; but I believe they are equally productive, although, if I leaned towards any side with my limited experience, I should say that the low land, such as at *Kahung*, which is not so low as ever to be inundated by the strongest rise in the river, is the best. The plants seem to love and court moisture, not from stagnant pools, but running streams. The *Kahung* tracts have the water in and around them ; they are all in heavy tree-jungles, which makes it very expensive to clear them. An extent of 300 yards by 300 will cost from 200 to 300 rupees (from L.20 to L.30) ; *i. e.* according to the manner in which the miserable opium-smoking Assamese work....Last season it was with the greatest difficulty that I could get a sufficient number of hands to gather the leaves. The plucking of the leaves may appear to many a very easy and light employment, but there are not a few of our coolies who would much rather be employed on any other job. The standing in one position so many hours occasions swellings in the legs, as our plants are not like those of China, only three feet high, but double that size, so that one must stand upright to gather the leaves. The Chinese pluck theirs squatting down. We lie under a great disadvantage in not having regular men to pluck the leaves ; those that have been taught to do so, can pluck twice as many as those that have not ; and we can seldom get hold of the same men two seasons running. I am of opinion that our trees will become of a smaller and more convenient size after a few years' cultivation ; because, trimming of the plants, and taking all the young leaves as soon as they appear, month after month, and year after year, and the plants being deprived of the rich soil they had been living on from time unknown, must soon tell upon them. Transplanting also helps to stunt and shorten the growth of these plants. The Chinese declared to me, that the China plants now at *Deenjoy* would never have attained to half the perfection they now have under ten years in their own country.
>
> " I may here observe, that the sun has a material effect on the leaves ; for as soon as the trees that shade the plants are removed, the leaf, from a fine deep green, begins to turn into a yellowish colour, which it retains for some months, and then again gradually changes to a healthy green, but now becomes thicker, and the plant throws out far more numerous leaves than when in the shade. The more the leaves are plucked, the greater number of them are produced. If the leaves of the first crop were not gathered, you might look in vain for the leaves of the second crop. The tea made from the leaves in the shade is not near so good as that from leaves exposed to the sun ; the leaves of plants in the sun are much earlier in season than of those in the shade ; the leaves from the shady tract give out a more watery liquid when rolled, and those from the sunny a more glutinous substance. When the leaves of either are rolled on a sunny day, they emit less of this liquid than on a rainy day. This juice decreases as

the season advances. The plants in the sun have flowers and fruit much earlier than those in the shade, and are far more numerous; they have flowers and seeds in July, and fruit in November. Numerous plants are to be seen, that, by some accident, either cold or rain, have lost all their flowers, and commence throwing out fresh flower-buds more abundantly than ever. Thus it is not unfrequent to see some plants in flower so late as March (some of the China plants were in flower in April), bearing at once the old and the new seeds, flower-buds, and full-blown flowers,—all at one and the same time. The rain also greatly affects the leaves, for some sorts of tea cannot be made in a rainy day; for instance the *Pouchong* and *Mingehew*. The leaves for these ought to be collected about 10 A. M. on a sunny morning, when the dew has evaporated. The *Pouchong* can only be manufactured from the leaves of the first crop; but the *Mingehew*, although it requires the same care in making as the other, can yet be made from any crop, provided it is made on a sunny morning. The Chinese dislike gathering leaves on a rainy day for any description of tea, and never will do so unless necessity requires it. Some pretend to distinguish the tea made on a rainy and on a sunny day, much in the same manner as they can distinguish the shady from the sunny teas—by their inferiority. If the large leaves for the black tea were collected on a rainy day, about seven seers, or fourteen pounds, of green leaves would be required to make one seer, or two pounds, of tea; but if collected on a sunny day, about four seers, or eight pounds, of green leaves, would make one seer, or two pounds, of tea;—so the Chinamen say. I tried the experiment, and found it to be correct. Our season for tea-making generally commences about the middle of March, the second crop in the middle of May, the third crop about the first of July; but the time varies according to the rains setting in sooner or later. As the manufacture of the *Sychee* and *Mingehew* black teas has never been described, I will here attempt to give some idea how it is performed.

"*Sychee* Black Tea.—The leaves of this are the *Souchong* and *Pouchong*. After they have been gathered and dried in the sun in the usual way, they are beaten and put away four different times; they are then put into baskets, pressed down, and a cloth put over them. When the leaves become of a brownish colour by the heat, they throw out and have a peculiar smell, and are then ready for the pan, the bottom of which is made red-hot. This pan is fixed in masonry breast high, and in a sloping position, forming an angle of forty degrees. Thus the pan being placed on an inclined plane, the leaves when tossed about in it cannot escape behind, or on the sides, as it is built high up, but fall out near the edge close to the manufacturer, and always into his hands, so as to be swept out easily. When the bottom of this pan has been made red-hot by a wood fire, the operator puts a cloth to his mouth, to prevent inhaling any of the hot vapour. A man on the left of him stands ready with a basket of prepared leaves; one or two men stand on his right with dollahs, or shallow baskets, to receive the leaves from the pan, and another keeps lifting the hot leaves thrown out of the pan into the dollah, that they may quickly cool. At a given signal from the Chinaman, the person with the basket of prepared leaves seizes a handful and dashes it as quick as thought into the red-hot pan. The Chinaman tosses and turns the crackling leaves in the pan for half a minute, then draws them all out by seizing a few leaves in each hand, using them by way of a brush, not one being left behind. They are all caught by the man with the dollah or basket, who, with his disengaged hand, continues lifting the leaves and letting them fall again, that they may quickly cool. Should a leaf be left behind in the pan by any accident, the cloth that is held ready in the mouth is applied to brush it out; but all this is done as quick as lightning. The man that holds the basket of leaves watches the process sharply; for no sooner is the last leaf out of the pan, than he dashes in another handful, so that, to an observer at a little distance, it appears as if one man was dashing the leaves in, and the other as fast dashing them out again—so quickly and dexterously is this managed. As soon as one basket has received about four handsful of the hot leaves from the pan, it is removed, and another basket placed to receive the leaves; and so on, until all is finished. A roaring wood fire is kept up under the pan, to keep the bottom red-hot, as the succession of fresh leaves tends greatly to cool the pan, which ought always to be scrubbed and washed out after the process is over. In China these pans are made of cast iron, and if great care is not taken, they will crack in the cooling; to prevent which, one man keeps tapping the inside of the edge of the pan briskly with a wet broom. used in the cleaning of the vessel, while another pours cold water in gently; thus it cools in a few seconds, and is ready for another batch of tea. The leaves are rolled and tatched the same as the other teas, and put into the drying basket for about ten minutes. When a little dry, people are employed to work and press the leaves in the hands in small quantities, of about one and half to two rupees' weight at a time, for about half a minute; they are then put into small square pieces of paper, and rolled up; after this they are put into the drying basket, and permitted to dry slowly over a gentle fire for some hours, until the whole is thoroughly dry. This tea is not sold in the China market; it is used principally as offerings to the priests, or kept for high days and holidays. It is said to be a very fine tea, and there is not one man in a hundred who can make it properly. The *Pouchong* tea is made in the same way as the *Sychee*, with this exception, that it is not formed into balls.

"*Mingehew* Black Tea.—The leaves (*Pouchong*) are plucked and dried in the sun, and are then beaten and dried in the shade for half an hour. This is done three successive times, and the leaves are very much shaken by a circular motion given to them in a sieve, so as to keep them rolling and tumbling about in the centre of it. This treatment continues until they are very soft; they are then allowed to remain for a short time. The contents of the first sieve are then placed in the centre of a close-worked bamboo basket, with a narrow edge, and the leaves are divided into four equal parts. The contents of the second sieve are placed in another bamboo basket like the former, and this basket is placed on the top of the first, and so on, piling one basket upon another, until all is finished;—there may be about two pounds of leaves in each basket. The red-hot pan is used the same as in *Sychee*, only now the men cast in one division of the leaves into the basket, and this is tumbled and tossed about in the red-hot pan like a plaything for about thirty seconds, and then swept out; another division is cast in, and so on, until all the prepared baskets have been emptied. The contents of each basket are still kept separate, by placing the leaves, when they come out of the pan, in separate baskets. The whole is a brisk and lively scene, and quite methodical, every one knowing his station, and the part he has to perform. The baskets are then arranged on shelves to air; the contents are afterwards tatched the same as our black teas, and fired in the drying baskets. but with this difference, that each division is placed on paper and dried. When it is half dry (the same as our teas), it is put away for the night, and the next morning it is picked, and put into the drying baskets over gentle deadened fires, and gradually dried there; it is then packed hot. This tea is a difficult sort to make.

"*Shung Paho* Black Tea.—Pluck the young (*Paho*) leaf that has not yet blown or expanded, and has the down on it, and the next one that has blown, with a part of the stalk; put it into the sun for half an hour, then into the shade; tatch over a gentle fire, and in tatching roll the leaves occasionally in the pan, and spread them all round the sides of the same; again roll them until they begin to have a withered and soft appearance, then spread them on large sieves, and put them in the shade to air for the night; next morning pick, and then fire them well. Some tea-makers do not keep them all night, but manufacture and pack the tea the same day. This tea is valued in China, as it is very scarce; but the Chinamen acknowledge that it is not a good sort. They prefer the teas the leaves of which are come to maturity."

"As the green-tea Chinamen have just commenced operations, I will try to give some account of this most interesting process. All leaves up to the size of the *Souchong* are taken for the green tea. About three pounds of the fresh leaves, immediately they are brought in, are cast into a hot pan (sometimes they are kept overnight when abundance have been brought in, and we have not been able to work all up); they are then rolled and tossed about in the pan, until they become too hot for the hand. Two slips of bamboo, each about a foot long, split at one end so as to form six prongs, are now used to tumble and toss the leaves about, by running the sticks down the sides of the pan, and turning the leaves up, first with the right hand, then with the left, and this as fast as possible; which keeps the leaves rolling about in the pan without being burnt: this lasts about three minutes; the leaves will then admit of being rolled and pressed without breaking. They are now taken from the pan, and rolled in dollahs, much the same as the black tea, for about three minutes, in which process a great quantity of the juice is extracted, if they be fresh leaves; but if they have been kept over night, very little juice can be expressed from them in the morning, on account of its having evaporated. The Chinamen say this does not matter, as it makes no difference in the tea. The leaves are then pressed hard between both hands, and turned round and pressed again and again, until they have taken the shape of a small pyramid. They are now placed in bamboo baskets or dollahs with a narrow edge, and the dollahs or bamboo frame-work, where they are exposed to the sun for two or three minutes, after which these pyramids of tea are gently opened, and thinly spread on the dollahs to dry. When the tea has become a little dry (which will be the case in five or ten minutes if the sun be hot), it is again rolled, and then placed in the sun as before; this is done three successive times. But should the weather be rainy, and there is no hope of its clearing, all this drying is done over the fire in a small drying basket, the same as with black tea. The green-tea makers have as great an aversion to drying their tea over the fire as the black-tea makers. The third time it has been rolled and dried, there is very little moisture left in the tea. It is now put into a hot pan. and gently turned over and over, and opened out occasionally, until all has become well heated; it is then tossed out into a basket, and while hot, put into a very strong bag, previously prepared for it, about four feet long, and four spans in circumference. Into this bag the tea is pressed with great force with the hands and feet; from fourteen to twenty pounds being put in at one time, and forced into as small a compass as possible. With his left hand the man firmly closes the mouth of the bag immediately above the leaves, while with the right hand he pommels and beats the bag, every now and then giving it a turn. Thus he beats, and turns, and works at it, tightening it by every turn with one hand, and holding on with the other, until he has squeezed the leaves into as small a compass as possible at the end of the bag. He now makes it fast by turns of the cloth where he held on, so that it may not open, and then draws the cloth of the bag over the ball of leaves, thus doubling the bag, the mouth of which is twisted and made fast. The man then stands up, holding on by a post or some such thing, and works this ball of leaves under his feet, at the same time alternately pressing with all his weight, first with one foot and then the other, turning the ball over and over, and occasionally opening the bag to tighten it more firmly. When he has made it almost as hard as a stone, he secures the mouth well, and puts the bag away for that day. Next morning it is opened out, and the leaves gently separated and placed on dollahs, then fired and dried until they are crisp, the same as the black tea, after which they are packed in boxes or baskets. In China the baskets are made of double bamboo, with leaves between. The tea may then remain on the spot for two or three months, or be sent to any other place to receive the final process. This first part of the green-tea process is so simple, that the natives of this country readily pick it up in a month or two. The second process now commences by opening the boxes or baskets, and exposing the tea on large shallow bamboo baskets or dollahs, until it has become soft enough to roll, it is then put into cast-iron pans set in brick fire-places, the same as described in making the *Sychee* black tea. The pan is made very hot by a wood fire, and seven pounds of the leaves are thrown into it and rubbed against the pan, with the right hand until tired, and then with the left, so as not to make the process fatiguing. The pan being placed on an inclined plane, the leaves always come tumbling back towards and near the operator, as he pushes them up from him, moving his hands backwards and forwards and pressing on the leaves with some force with the palms, keeping the ends of the fingers up to prevent their coming in contact with the hot pan. After one hour's good rubbing, the leaves are taken out and thrown into a large coarse bamboo sieve, from this into a finer one, and again still finer one, until three sorts of tea have been separated. The first, or largest sort, is put into the funnel of the winnowing machine, which has three divisions of small traps below, to let the tea out. A man turns the wheel with his right hand, and with the left regulates the quantity of tea that shall fall through the wooden funnel above, by a wooden slide at the bottom of it. The tea being thrown from the sieves into the funnel, the man turns the crank of the wheel, and moves the slide of the funnel gradually, so as to let the tea fall through gently, and in small quantities. The blast from the fan blows the smaller particles of tea to the end of the machine, where it is intercepted by a circular moveable board placed there. The dust and smaller particles are blown against this board, and fall out at an opening at the bottom into a basket placed there to receive it. The next highest tea is blown nearly to the end of the machine, and falls down through a trough on the side into a basket; this tea is called *Young Hyson.* The next being a little heavier, is not blown quite so far; it falls through the same trough, which has a division in the middle; this of course is near the centre of the machine. A basket is placed beneath to receive the tea, which is called *Hyson.* The next, which is still heavier, falls very near to the end of the fan, this is called *Gunpowder* Tea; it is in small balls. The heaviest tea falls still closer to the fan, and is called *Big Gunpowder;* it is twice or three times the size of *Gunpowder* tea, and composed of several young leaves that adhere firmly together. This sort is afterwards put into a box and cut with a sharp iron instrument, then sifted and put among the *Gunpowder,* which it now resembles. The different sorts of tea are now put into shallow bamboo baskets, and men, women, and children are employed to pick out the sticks and bad leaves; this is a most tedious process, as the greatest care is taken not to leave the slightest particle of any thing but good tea. But to assist and quicken this tiresome process, beautiful bamboo sieves, very little inferior to our wire ones, and of various sizes, are employed. The different teas are thrown into sieves of different sizes, from large gunpowder to dust tea; they are shaken and tossed, and thrown from one person to another in quick succession, making the scene very animating; in this way a great portion of the stalks are got rid of. After the tea has been well sifted and picked, it is again put into the hot pans, and rubbed and rolled as before, for about one hour; it is then put into shallow bamboo baskets, and once more examined, to separate the different teas that may still remain intermixed, and again put into the hot pan. Now a mixture of sulphate of lime and indigo, very finely pulverised and sifted through fine muslin, in the proportion of three of the former to one of the latter, is added; to a pan of tea containing about seven pounds, about half a tea-spoonful of this mixture is put, and rubbed and rolled along with the tea in the pan for about an hour, as before described. The tea is then taken hot from the pan and packed firmly in boxes, both hands and feet being used to press it down. The above mixture is not put to the tea to improve its flavour, but merely to give it a uniform colour and appearance, as without it some of the tea would be light and some dark. The indigo gives it the colour, and the sulphate of lime fixes it. The Chinese call the former *Youngtin,* the latter *Acco.* Large gunpowder tea they call *Tychen;* little gunpowder, *Cheocheu;* hyson, *Chingcha;* young hyson, *Uchin;* skin tea, or old leaves in small bits, *Poocha;* the fine dust or powder tea, *Chamoot.*

"The leaves of the green tea are not plucked the same as the black, although the tree or plant is one and the same, which has been proved beyond a shadow of doubt; for I am now plucking leaves for both green and black from the came tract and from the same plants; the difference lies in the manufacture, and nothing else. The green-tea gatherers are accommodated with a small basket, each having a strap passed round the neck, so as to let the basket hang on the breast. With one hand the man holds the branch, and with the other plucks the leaf, one at a time, taking as high as the *Souchong* leaf; a little bit of the lower end of the leaf is left for the young leaf to shoot up close to it; not a bit of stalk must be gathered. This is a very slow and tedious way of gathering. The black-tea maker plucks the tea with great rapidity with both hands, using only the forefinger and thumb, and collects them in the hollow of the hand; when his hand is full he throws the leaves into a basket under the shade of the tree; and so quickly does he ply his hands that the eye of a learner cannot follow them, nor see the proper kind of leaf to be plucked; all that he sees is the Chinaman's hands going right and left, his hands fast filling, and the leaves disappearing.... *Paho* black tea leaf would make green tea, some gunpowder, and some young hyson. *Pouchong,* although classed as a second black tea, on account of the high price it fetches in the market, is a third-rate leaf, for it is rather larger than the *Souchong.* Some of it would make young hyson, and some skin tea. *Souchong* would make hyson and young hyson. *Toychong* would make skin tea. I will here mention the different kinds of black teas, to make the matter more clear to those who take an interest in the subject. *Thowung-Paho* (the *Sung fa* is the same leaf as this) is the downy little leaf not expanded, and the one next to it that has just unfolded a little. This tea when made appears full of small white leaves, which are the little downy leaves just mentioned. *Twazee Paho* is from the second crop, and nearly the same kind of tea, only a little older; the leaf next the small downy one (being a little more expanded), and the small leaf below this, are taken, making three in all: this has also numerous white leaves, but not so many as the former. *Souchong* is the next largest leaf; this is well grown, but embraces all the leaves above it. When the upper leaves have grown out of season for *Thowung-Paho* and *Twazee-Paho,* they are all plucked for the *Souchong* from the third and fourth of the upper leaves. From *Souchong* leaves the *Minchong* and *Sychee* teas are made in the first crop, and no other. *Pouchong* is the next largest leaf; it is a little older and larger than the *Souchong.* From this leaf the *Sychee* and *Minchong* teas can be made in the first crop only. The *Pouchong* is never made in the second crop, on account of its not having a good flavour; many of the *Souchong* leaves are mixed up in this tea. The *Toychong* leaves are those that are rejected from the *Souchong* and *Pouchong,* as being too large and not taking the roll. When the teas are picked, these leaves are put on one side. The Chinese often put them into a bag, and give them a twist, something in the green tea way, and then mix them up with the *Souchong* to add to the weight. This leaf (*Toychong*) becomes worse in the second and third crops;—it is a cheap tea and sold to the poor. All the black teas that are damaged have the flower of what the Chinese call *Qui fa,* another called *Son fa,* mixed up with them. One pound of the flowers is put to each box of damaged tea. After the teas have been well tatched and mixed up with other sorts, these leaves give them a pleasant fragrance. The *Son fa* plant is about two feet high, and kept in flower-pots; it is propagated from the roots. The *Qui fa* plant is from three to four feet high; one pound of the flowers is put to a box of tea. The plant was seen in the Botanical Gardens at Calcutta by our Chinese interpreter. The flowers of this plant are considered finer than those of the *Son fa.*"

"The black-tea makers appear to me to be very arbitrary in their mode of manufacture; sometimes they will take the leaves of the *Thowung-Paho,* or perhaps *Twazee-Paho;* but if it has been raining, or there is any want of coolies to pluck the leaves quickly, or from any other cause, they will let the leaves grow a few days longer, and turn all into *Souchong;* which, it must be remembered, takes all the small leaves above it. If it is the first crop, the *Souchong* and *Pouchong* leaves may all be turned into *Souchong* tea; but even if it is the second crop, when the *Pouchong* leaves ought not to be gathered, they are nevertheless plucked and mixed up with the *Souchong* leaves. Almost all our black and all the green teas have just been made from one garden. When the green-tea makers complained that the leaves were beginning to get too large for them—that is, they were fast growing out of *Souchong* and running into *Pouchong*—the black-tea makers took up the manufacture, plucked all the leaves, and made excellent *Pouchong;* so that between the two there is not a leaf lost. When the black-tea makers have a garden to themselves they are cruel pluckers, for they almost strip the tree of leaves for the *Souchong,* and are not at all nice in the plucking; the third and even the fourth leaf on a tender twig is nipped off in the twinkling of an eye; they then look about for more young leaves, and away go the *Pouchong,* and *Toychong* too, which is the largest leaf of all. But the green-tea men pluck quietly, one by one, down to *Souchong.* The black-tea men separate all their teas into first, second, third, and fourth crop; but the green-tea manufacturers make no distinction; they prepare all the tea they can, throughout the season, box or basket it up, and when the season is over, they set off for Canton with their produce; at least all those who do not wish to sell their tea on the spot. The different merchants go in quest of it there. It now indiscriminately undergoes the second process; that is, the different crops all are mixed up together. No old leaves can be mixed in the green, as in the black teas; for the long rolling in the pan crushes them, and the fan blows them away, so that only the young leaves are left."—[Report on the Manufacture of Tea, and the Tea Plantations in Assam, by C. A. Bruce, presented to the Tea Committee, 10th June 1839.]

Tea was introduced into Europe in the year 1610, by the Dutch East India Company. It is generally said that it was first imported from Holland into England in 1666, by the Lords Arlington and Ossory. But that it was used in coffee-houses before this period, appears from an act of parliament passed in 1660, in which a duty of eightpence was laid on every gallon of the infusion sold in these places; and from the following entry which appears in the Diary of Mr Pepys, secretary to the Admiralty,—"September 25, 1661: I sent for a cup of tea (a Chinese drink), of which I never drunk before." In 1664, the East India Company bought 2 lbs. 2 oz. as a present to his majesty; and in 1667 they issued their first order to their agent at Bantam, to send home 100 lbs. of the best tea he could get. It continued to be sold in London for 60s. per lb. till 1707, though it did not cost more than 2s. 6d. or 3s. 6d. at Batavia. In 1689, instead of charging a duty on the decoction from the leaves, a duty of 5s. per lb. was laid on the tea itself. In 1715 green tea began to be used, and as great quantities were then imported, the price was proportionally lowered. In 1790 the quantity of tea retained for home consumption in Great Britain and Ireland was 1,643,095 lbs., and the duty amounted to L.580,362. Since that period the trade in tea has rapidly continued to increase till it has arrived at its present astonishing magnitude. Till 1833 the East India Company enjoyed a monopoly of the trade in tea, but by the act 3 and 4 William IV., c. 93, the trade was thrown open.

Sugar and tea are the most productive to the chancellor of the exchequer, of all the exciseable imports. These two articles alone yielded in 1836 a net revenue of L.8,858,700. In 1836 the net revenue from tea was L.4,184,165, and the quantity retained for home consumption was 49,142,236 pounds; in 1837 the net revenue was L.3,223,840, and the quantity retained for home consumption 30,625,206 pounds. The ease with which it can be levied has always been a great temptation to lay a heavy duty on this commodity; and the consequence has been, that this, which may now be termed a necessary of life, has been burdened to the utmost limit of productiveness, and sometimes considerably beyond it. Previously to the 1st of July 1837, the duty, which had varied greatly from time to time, was, for Bohea, 1s. 6d. per pound; Congou, Twankay, &c. 2s. 2d.; and Souchong, Hyson, 3s. From that date a uniform duty of 2s. 1d. is charged on all sorts. Thus it appears, from the table of sales by the East India Company, that the duty on Bohea is nearly 300 per cent., the price of the pound of Bohea being 9$\frac{2}{10}$d., and the tax upon it 2s. 1d. On the other sorts the tax is about 100 per cent. It may fairly be anticipated, that a considerable reduction of duty on this healthful beverage would promote the comfort and sobriety of the community, without diminishing the amount of the revenue, in consequence of the increase of consumption which would necessarily follow.

When imported into the United States in American vessels it is duty free; but a duty of ten cents, or 5d. per pound, is laid on what is imported in foreign vessels.

An Account of the Quantities and Prices of the several sorts of Tea sold in England by the East India Company, in the year 1837 (*May to December*).

The quantity exported by the Dutch and other nations, as compared with the exports of the British and Americans, is very small. Except Britain, Holland and Russia are the only European states in which the consumption of tea is considerable. In 1832 the imports into Russia were 6,461,064 lbs.; in Holland they amount to about 2,800,000 annually. By the last accounts from Canton, the quantity of teas shipped from Hongkong and Tongkoo for England, since the first of July 1839, was, of Black Congou, 4,643,609 lb.; Caper, 21,042 lb.; Souchong, 31,174 lb.; Pekoe, 66,900; and Orange Pekoe, 271,623 lb. Of green tea the quantities were, Hyson, 282,400; Young Hyson, 45,778 lb.; Hyson Skin, 38,700 lb.; Twankay, 1,222,907 lb.; Gunpowder, 138,009 lb.; and Imperial, 60,010 lb.

TEACHERS, persons employed in conducting the education of the young. See the articles Schools and Universities.

TEARY, a large village of Hindustan, in the province of Malwah, with a fort on an adjoining hill. Long. 79. 3. E. Lat. 24. 46. N.

TEBALA, a town of Arabia, province of the Hedsjas, 128 miles south-south-east of Mecca.

TEBETH, the tenth month of the Jewish ecclesiastical year, and fourth of the civil. It answers to our month of December.

TECHNICAL expresses somewhat relating to arts or sciences: in this sense we say technical terms. It is also particularly applied to a kind of verses in which are contained the rules or precepts of any art, thus digested to help the memory to retain them. An example may be seen in the article Memory.

TECRIT, a town of Irak Arabi, in the province of Mosul, on the western bank of the Tigris. It is thought to be the Birtha or Vitra of the ancients, described as a very strong fortress, and said to be founded by Alexander the Great. It was a considerable town in 1393, when it was taken by Timur, and now contains 500 or 600 houses, with two coffee-houses. The ruins are extensive. Long. 42. 37. E. Lat. 34. 37. N.

TEDDINGTON, a town, or rather a village, in the hundred of Spelthorne and county of Middlesex, twelve miles from London. It is delightfully placed on the banks of the Thames, at the spot where the tide ceases to flow, from which circumstance the name has been given to the place. It has a neat parish church; and within the parish are many splendid houses and a great number of country retreats for the inhabitants of the metropolis. Bushy Park, which adjoins it, is an attractive object, affording pleasing promenades and rides. The population in 1821 amounted to 863, and in 1831 to 895.

TE DEUM, the name of a celebrated hymn, used in the Christian church, and so called because it begins with these words, *Te Deum laudamus*, We praise thee, God. It is sung in the Romish church with great pomp and solemnity upon the gaining of a victory, or other happy event; and is believed to be the composition of St Ambrose, bishop of Milan.

TEDIF, a town of Syria, in the pachalic of Aleppo, where is a Jewish synagogue. It is twenty-one miles east of Aleppo.

TEDZEN, a considerable river of Persia, in the province of Khorassan, and the largest in this part of Asia next to the Oxus. After a course from east to west, it falls into the Gulf of Balkan, on the eastern coast of the Caspian.

TEEBAKAN, a small island in the Eastern Seas, near the north coast of Borneo. Long. 117. 39. E. Lat. 7. 52. N.

TEEHEENGAN, a small island in the Eastern Seas, north of Borneo. Long. 117. 30. E. Lat. 7. 49. N.

TEEKOOL, a small island near the Sooloo archipelago. Long. 125. 25. E. Lat. 6. 6. N.

TEES, a river which rises on the confines of Cumberland, and running eastward, divides the county of Durham from Yorkshire, and falls into the German Ocean below Stockton.

TEESGAON, a town of Hindustan, province of Aurungabad. Long. 74. 53. E. Lat. 19. 13. N.

TEESTA, a considerable river of Bengal, which has its source in the Himalaya Mountains, and after dividing the Nepaul country from the dominions of the Deb rajah, enters the northern region of Rungpoor. It thence takes a northerly course till it joins the Ganges.

TEETGAUM, a town of Hindustan, province of Gujerat, district of Neyer, situated about twelve miles south-west from Theraud. Its inhabitants are Hindus of a military tribe. Latitude not ascertained.

TEETH, the bones placed in the jaws for chewing food, that it may be the more easily digested in the stomach. The anatomical structure of the teeth has been described under Anatomy.

TEFF, a kind of grain, sown all over Abyssinia, from which is made the bread commonly used throughout the country. We have no description of this plant but from Mr Bruce, who says that it is herbaceous; and that from a number of weak leaves surrounding the root proceeds a stalk of about twenty-eight inches in length, not perfectly straight, smooth, but jointed or knotted at particular distances. This stalk is not much thicker than that of a carnation or julyflower. About eight inches from the top, a head is formed of a number of small branches, upon which it carries the fruit and flowers; the latter of which is small, of a crimson colour, and scarcely perceptible by the naked eye but from the opposition of that colour. The pistil is divided into two, seemingly attached to the germ of the fruit, and has at each end small capillaments forming a brush. The stamina are three in number; two on the lower side of the pistil, and one on the upper. These are each of them crowned with two oval stigmata, at first green, but afterwards crimson. The first is formed in a capsula, consisting of two conical hollow leaves, which, when closed, seems to compose a small conical pod, pointed at the top. The fruit or seed is oblong, and is not so large as the head of the smallest pin; yet it is very prolific, and produces these seeds in such quantity as to yield a very abundant crop in the quantity of meal. From the similarity of the names, Mr Bruce conjectures it to be the *tipha* mentioned but not described by Pliny; but this conjecture he acknowledges to be unsupported.

TEFLIS, or Tiflis, a city of Asia, and capital of the kingdom of Georgia, situated on the precipitous banks of the Kur, at the foot of a line of dark and barren hills, which overshadow the town, and impart to it a gloomy appearance. This city was visited by Sir R. K. Porter in 1817, and from his work the following account is chiefly compiled. Teflis has no claim to a very high antiquity, having been founded in 1063 by the czar Liewang, who was attracted to the spot by certain warm springs in the neighbourhood, from which he expected to derive benefit. Before that period it could boast of no habitation in the form of a house, with the exception of a few mud hovels for the convenience of the occupiers of a small fortress which stood on an adjacent height, and protected the valley, and of which the remains are still to be seen on a hill to the south of the town, at some distance from the station of the more modern citadel, which is of Turkish origin. The road along the western bank of the Kur was completely commanded by this old work of the native czars; and its dark and frowning towers still seem to threaten the passenger below. The first aspect of the town appeared to Sir R. K. Porter peculiarly gloomy; and though these impressions were in some degree lessened by greater familiarity, the effect of the surrounding scenery always remained the same; and the town seemed to be enclosed in a vast prison of high and beetling rocks, broken into deep clefts, black and bare, and projecting into a thousand rugged and savage forms. So confined an abode is far from being desirable; and hence the governor-general has chosen his place of residence at a short distance from the body of the city, on the gentle slope of a hill fronting the river, with a fine view of the Caucasus Mountains. This building, with the arsenal, the hospital, churches, and a few villas in the neighbourhood, is all that bears any resemblance to the architecture of Europe. The rest is purely Asiatic, in the most unfavourable sense of the term, being a collection of low, flat-roofed dwellings, built of dun brick, mingled with stones and mud; the doors and windows exceedingly small; the latter covered with paper instead of glass. The streets are all narrow, and covered with deep mud or dust, according as the weather is wet or dry. The Russian governor has begun to remedy this defect by ordering them to be paved. He has also introduced other improvements, by directing old and ruinous houses to be pulled down, and others more handsome and spacious to be erected in their stead. Among other improvements, the bazaar, or great market-place for merchants, has undergone important alterations. It has been totally roofed in, but with open circles left in the rafters for the admission of air and light. It is united with the square of the city guard by long colonnades, which place is also lined with shops, covered from the weather with a fine range of pillared arcades. The natives themselves begin to be sensible of these improvements, when they experience the comfort of shelter for themselves and their merchandise, from the injurious effects of rain or scorching heat. The bazaar is a narrow street, long and winding. It is lined on each side with shops of every description, such as those of fruiterers, grocers, barbers, cooks, mercers, saddlers, armourers, and various other traders, who all display their articles to the best advantage. Notwithstanding the value of the merchandise here exposed, the place is a free thoroughfare, not merely to pedestrians, but to horsemen, and asses with burdens, and even to droves of buffaloes. Hence it is often both disagreeable and dangerous to foot passengers, though it is still a bustling scene, full of people from morning till night. Not far from the bazaar is the public caravanserai, which is a circular building, three stories in height, with a sort of gallery running in front of each range of doors, from which stone-steps descend to conduct passengers above or below. Here the merchants take up their quarters; and here may be seen exposed on the stone or earthen floors of dark and vaulted apartments, whatever goods the merchants who inhabit them possess. The owner of each heap sits cross-legged, in grave attendance, waiting the appearance of customers, or bargaining with those who arrive. The centre of the court is filled with the horses and mules of the merchants in the caravanserai.

Teflis has been long famed for its hot baths, which possess valuable medicinal properties, and are frequented by both sexes for health as well as for luxury and amusement. These baths are situated at the extremity of the bazaar, where is a small bridge over a deep ravine, in which flows a mountain stream, pure and cold at its fountain head, but, mingling with the hot springs, which take their rise in the adjacent heights, it becomes warm. It is over this steaming flood that the baths are erected. On one side of the bridge stand those appropriated to the men, and on the other, immediately under the gloomy walks of the citadel, those allotted to the women. The water which supplies these baths is strongly impregnated with sulphur, having the usual offensive smell of such springs. Its heat may be reckoned at from 15 to 36 degrees of Reaumur in the several basins; and at the source the heat is 42 degrees. The basins are excavated in the solid rock, over whose surface the water had originally flowed; and these are divided, under one immense vaulted roof, into different apartments, from which the day-light is entirely excluded, and where total darkness is only dispelled by the faint glimmering of a few lamps twinkling amid the vapours from the steam. These baths are open to all ranks indiscriminately, and are in a state of the greatest disorder and filth. There is not a place where a bather could lay down his clothes without having them drenched in wet, and dirtied. In journeying farther into the interior of these boiling caverns, Sir R. K. Porter found an accumulation of every thing that can disgust the senses. All sorts of people were huddled together, scrubbing, scraping, rubbing, shaving, &c.; these offices being done in each case by the companions of the bather, or by the persons of the bath in attendance. He also visited the baths appropriated to the females, into which he was admitted without the least scruple.

The citadel is situated on the summit of a very high promontory, which forms the termination of the mountain that overshadows the town on its south-western side. This fortress was erected in 1576, when the Turks took possession of Georgia, to overawe the conquered province. About two centuries afterwards it was dismantled by the Persians when they overran the country, and was left gradually to decay. It exhibits a mass of ruins, which however are still grand and imposing; and the situation in which they are placed increases the wildness and majesty of these eastern towers. Within the old battlements may still be seen the remains of the mosque mentioned by Chardin, and which is now used as a prison for malefactors, under an officer and guard. Besides this fortress, the Turks, for greater security, enclosed the town on every side with a range of towers and walls; but these ancient bulwarks, like the citadel itself, are now, with the exception of the wall facing the river, nearly levelled with the ground. There are several fine churches in Teflis, of different Christian persuasions. That which is dedicated to the Catholic mode of worship is the most beautiful. The great Armenian church, the cathedral of Holy Zion, is more extensive, but is not equal to the other either in richness or grace of architecture; yet its more advantageous situation adding the majesty of nature to the holy sanctity of the place, seems fully to bear out the propriety of its appellation. The noble waters of the Kur roll past its base, increasing in rapidity and sound as they pour onward through the bold cliffs, which, narrowing, contract the rapid stream. Here a bridge of a single arch connects the town with a considerable suburb called Avlabar. It is chiefly inhabited by a colony of Armenians who fled from the neighbourhood of Erivan during the late wars between Russia and Persia. Here are also the ruins of an ancient fort, church, and houses; and about two miles farther from this side of the city stand the remains of another sacred and ancient edifice, on the summit of a hill so high that it commands the most extensive view in the vicinity of Teflis; embracing on one side the city, with its citadel, churches, and gardens; on the other, to the north, the windings of the Kur through the varied shores of the valley and the plain; with the whole chain of mountains from the province of Kahetia to Kasibeck, and their tremendous summits, pile above pile as far as the eye can reach to the north-west, the snowy summit of Elborus towering in the distance to the height, according to the calculation of a Russian officer, of 16,700 feet above the level of the sea.

From their intercourse with the Russians, the higher classes of the inhabitants have gradually lost much of their Asiatic manners; and such changes not being well understood by those who adopt them, are not in many cases favourable to the improvement of the people. In this case the Asiatics, set free from the restraints imposed by their own manners, have not adopted those of Europe; and have thus become more licentious than before. The women, having broken through the restraint that concealed their faces from all but their husbands, have also thrown off other restraints. They were at first extremely offended and disgusted when the Russian troops were quartered in their houses, and when they were first obliged to appear before them; but custom at last rendering them familiar to this intercourse, a great change has, within the last twenty years, been effected in the conduct of the female Georgians. Among the lower classes this effect of foreign intercourse has been even more decided. When they go abroad, they still retain the chadre, or veil, in which they are enveloped from head to foot; but when they are seen standing at their doors without this safeguard, they, from old custom, retreat hastily into the house from the gaze of strangers. They have been long celebrated for their beauty, having fine large dark eyes, regular features, and a pleasing and mild expression of countenance. Before its capture in 1757 by Aga Mahommed Khan, it contained 4000 houses, and 22,000 inhabitants. The population does not now exceed 15,000, though it is on the increase since the country came into the possession of the Russians, whose vigorous government gives protection to life and property. It is well situated for an entrepôt of trade; and Fraser mentions that it is fast rising from the ruinous condition in which the Russians received it, to be a thriving commercial place. The government gives every encouragement to industry: the port is declared free to all goods upon payment of an *ad valorem* duty of five per cent. at the Russian custom-house; and no internal duties are levied at toll-houses within their dominions. The distance from Redoubt Kaleh, on the Black Sea, to Teflis, is 230 miles. The Russian authorities are at present improving the road, and there are regular caravans from Teflis to Tabriz, which travel the journey in eighteen or twenty days, through a safe country. A trade has already commenced in such commodities as woollen cloths, cottons, plain and printed goods, hardware articles, silk and cotton manufactures of Lyon, embroideries, cloths, &c.; several cargoes of European goods having already reached Teflis from the Black Sea, and been sold with a large profit. This trade, it is probable, will gradually increase under the patronage of the Russian government, and hence Teflis bids fair to become, like Odessa, a commercial mart for an extensive district. From Petersburg it is distant 1752 English miles. Long. 62. 40½. E. Lat. according to the observation of Captain Monteith of the Madras engineers, 41. 43. N.

TEGADOO Bay, on the east coast of the most northern islands of New Zealand, discovered by Captain Cook in 1769. Long. 181. 14. W. Lat. 38. 10. S.

TEHAMA, a large belt of sand, which stretches along the eastern shore of the Red Sea, and extends as far as the mountains in the interior. It is entirely barren, presenting an unvarying picture of desolation. It bears every mark of having been anciently a part of the bed of the sea. It is increased by the blowing of the moving sands, which appear in this place to be continually making encroachments on the limit of the Red Sea. It contains large strata of salt, which in some places even rise into hills; and on the shore the banks of coral are perpetually increasing, so as every day more and more to augment the danger of navigating the gulf.

TEHERAN or Tehran, a large city of Persia, and during the last two reigns the residence of the sovereign, and hence considered to be the capital of the empire. It is situated on a very low tract of ground, near to the foot of the Elburz Mountains, in the province of Ajem. It is between four and five miles in circumference, and is surrounded by a strong wall, flanked by numerous towers and a broad dry ditch, with a glacis between it and the wall. It has, according to Sir R. K. Porter, four gates, though Morier says six. They are inlaid with coloured bricks, and with figures of tigers and other animals in rude mosaic. The streets, like those of all the other Persian towns, are narrow, and full of mud or dust according as the season is wet or dry. The plan in most of the eastern towns seems to have been to compress a numerous population within a small space; and hence the narrow streets and wretched alleys of which they consist, the heat, the crowd, and odious smell, which are fully as obnoxious to a European as the solar rays, against which the narrowness of the streets is supposed to be a defence. There is also another inconvenience, that when a khan or great personage goes out on horseback, as is generally the case, with a train of thirty or forty ill-appointed followers on foot, and when, besides, loaded camels, mules, asses, and not unfrequently one or two of the royal elephants, happen, as they often do, to be passing, they completely jam up the streets, to the evident hazard of life and limbs both to man and beast. Teheran is about the size of Shiraz. In summer, when the king quits it in order to pitch his tent in the plains of Sultania or Unjan, and when most of the inhabitants follow the royal camp, no more than 10,000 are left in the city; while in winter it contains between 60,000 and 70,000. The public edifices are not so numerous as in Shiraz; and as the city itself is built of bricks baked in the sun, it has a mud-like appearance. Of the mosques, the principal is the Mesjid, a structure not yet finished. There are six others, small and insignificant, and three or four colleges. The caravanserais are said to amount to 150, and there are 150 hummums or baths. There are two maidans or squares, one in the town, the other within the *ark*, a square fortified palace, which contains all the establishments of the king, is surrounded by a wall and ditch, and is entered by two gates. Half a century back, Teheran, the present metropolis of Persia, would hardly have been thought a town of sufficient importance for the capital of a province. It continued an obscure spot until Aga Mahommed Khan, uncle to the present shah, selected it for his residence. It had been destroyed by the Afghans at the beginning of the century, and afterwards rebuilt by Kurreen Khan: it was now improved by Mahommed Khan, and still further enlarged and embellished by his successor. As a central point of general surveillance for the safety of the empire, between the provinces to the north-west, which border on Georgia, and those to the east, which are subject to invasions from the Toorkomans, and their restless allies of Afghanistan, it is well chosen; but it is far from being a pleasant residence, being situated among swamps occasioned by the numerous spring torrents pouring from the adjacent heights, and saturating the low grounds about the town, from which the summer's sun exhales vapour and damp, so as to render this the most unhealthy season of the year. But the aspect of the place is far from disagreeable. The very humidity of the soil produces early verdure, and clothes the gardens with a more abundant shade; while the ranges of the Elburz Mountains stretch eastward behind the town, and in a direct line northward towers the peak of Demewand. Teheran is not known as one of the ancient cities of Persia. The first notices of its existence are in the fourteenth century. A Persian writer of that period remarks it as a large village, with productive gardens, in the vicinity of the city of Rey; and mentions that the inhabitants had their dwellings under ground, to avoid the excessive heats of summer, and also the attacks of their predatory neighbours. Teheran, according to observations of British officers lately resident in the city, is in Long. 50. 52. E. Lat. 35. 37. N.

TEHINCHIEN, a river of Hindustan, in the province of Bootan, which runs past Tassisudon, the capital; and being augmented by the tributary streams of the Hatchieu and Patcheiu, forces a passage through the mountains, whence it is precipitated into tremendous cataracts, and rushing with a rapid torrent between the high cliffs and vast rocks which oppose its progress, it pursues its course into the open plains near Buxedwar, and finally joins the Brahmapootra.

TEIGNMOUTH, West, a town of the hundred of Exminster, in the county of Devon, 187 miles from London. It stands on the sea-shore on Torbay, and adjoining to it, but on the opposite side of the river Teign, is East Teignmouth, a smaller and not a market-town. Both united form one of the most favourite resorts for sea-bathers on this coast, and it is frequently inhabited during the winter by persons afflicted with or apprehensive of pulmonary complaints. They are separate parishes, each having its church; and West Teignmouth has a good market on Saturdays. The country around is healthy and picturesque, and provisions are cheap. The population of West Teignmouth amounted in 1821 to 2514, and in 1831 to 2878; that of the other town in 1821 to 1466, and in 1831 to 1810.

TELEGRAPH.

TELEGRAPH, so named from two Greek words, *τέλος, end* or *distance*, and *γράφω, I write*, is a machine so constructed as to enable two persons to converse with each other at a distance, either by sentences, words, or letters, according to a convention previously agreed upon by the parties. Such a mode of communicating ideas beyond the reach of hearing is not, however, confined to any particular machine; the fingers of the human hand are quite sufficient, as every young boarding-school lady knows, for the purpose; and, when so applied, may be called a *telegraph*. Thus also the signal-flags used on board ships to communicate with each other, by making them represent letters or numbers, or both, constitute a *telegraph;* as may also the sending up of sky-rockets, blue lights, the suspension of lanterns, the making of fires on beacons, high hills, &c. be considered as telegraphic communications.

In imitation of the French, however, we have almost indiscriminately adopted the use of the word *semaphore* for the telegraph, which is perhaps of more extensive application, being derived from *σῆμα, a sign*, and *φέρω, I bear;* and may consequently be applied universally to whatever means may be used to communicate intelligence by signs or signals. Thus the firing of guns a certain number of times at certain intervals,—the notes of a trumpet, bugle, French horn, or other wind instrument,—the strokes on a drum,—may be used to convey information to a limited extent. The troops and marines which landed on the coast of America in the last war, when scouring the woods in detached parties, were regulated by the notes of the bugle, which were so clearly understood that no false movements were ever made. The immense number of barges and boats which crowd the Imperial Canal of China are directed in their movements, both by night and day, by the sound of the *gong*. The Indians of America convey intelligence from hill to hill by throwing out their arms with or without staves in them; by spreading their cloaks, holding up skins, &c.; and even the savage Hottentots, called Bosjeismans, the lowest probably in the scale of human beings, communicate with each other by arranging fires on the side of the hills in certain positions.

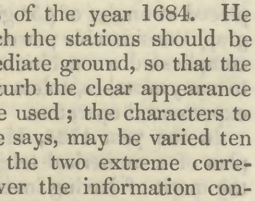
It is rather surprising that an art so simple as that of conveying ideas by means of signals, so well understood in remote antiquity, and practised even by savages, should have made so little progress in its improvement, that it may be said to have remained in its original rude state nearly down to our own times, when it has almost at once been brought to that state of perfection of which it appears to be capable.

One of the arguments usually adopted to prove that the art of conveying intelligence by signals was known in the early ages of Greece, is deduced from the opening of the *Agamemnon* of Æschylus, where the man on the watch-tower at the top of the palace announces the fire-signals having communicated the fall of Troy, long before any of the Greeks had returned from the siege; and Clytemnestra afterwards relates the stations; but this event of the burning of Troy, supposed thus to have been known in Greece soon after it happened, proves nothing more than that the use of signals was known to the poet, who wrote eight or nine hundred years after the event. Mention, however, is made by Jeremiah (ch. vi. v. 1), who was at least 200 years before Æschylus, of "setting up a sign of fire in Beth-haccerem;" and such signals are often alluded to by the prophets, as notices of the approach of an enemy.

The earliest decisive proof of telegraphic communications, except those by fires (πυρσεῖαι), being in use among the Greeks, is found in the methods described by Polybius. The Romans had their *vexillarii*, and used flags and other contrivances for regulating the movements of their armies; and they had hollow tubes constructed in the walls of their cities, by which they could communicate with the several ports or works by sound, as is done in our times in some manufactories by means of pipes or trumpets. Wherever the Romans pitched their camp, an elevated spot was selected for the signal station, to convey intelligence to the foraging parties or detachments; but it is nowhere stated to what extent this was carried. Vegetius alludes to something like a beam in the air, on the same principle perhaps as our semaphore.

In modern times, Kircher, who had more learning and less sense than any man of his day, and has written on almost every subject, gives an idea of telegraphic communication; and so does the ingenious Marquis of Worcester, in his Century of Inventions; but so vague as to convey no notion of the means he was to employ, except the use of colour; for the "discourse" to be held is stated to be "as far as eye can discover black from white." He also throws out a hint for a night telegraph, by which the same may be done, "though as dark as pitch is black." But almost every modern invention is supposed to exist in the mysterious "scantlings" of the Marquis of Worcester.

The first telegraph on record in modern times, applicable to universal purposes, is that of Dr Hooke, described in the Philosophical Transactions of the year 1684. He minutely details the mode in which the stations should be selected, their height and intermediate ground, so that the refraction of the air may not disturb the clear appearance of the object; the telescopes to be used; the characters to represent the alphabet, which, he says, may be varied ten thousand ways, and "none but the two extreme correspondents shall be able to discover the information conveyed;" and so convinced is he of the practical efficiency of his telegraph, as to leave no doubt on his mind, "that the same character may be seen at Paris within a minute after it hath been exposed in London." His method consisted in exposing in succession as many different shaped figures, or signs, at least, as the alphabet consists of letters. If used in the day-time, they might be squares, circles, triangles, &c. made of deals; if at night, torches or other lights disposed in a certain order. These characters or signs were to be brought forth from behind a screen on rods, as they might be wanted, and exposed to view. The accompanying figure, where A is the screen, and



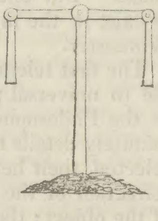
one of the signs exhibited, will convey an idea of Dr Hooke's telegraph.

Monsieur Amantons, of the Royal Academy of Paris, made an experiment to convey intelligence, which was highly approved of by the other members, and several persons of distinction belonging to the court. By the description given of the machine, it seems to have differed very little from that of Hooke already published in the Philosophical Transactions; the signals being either large letters of the alphabet, or figures of various shapes to represent them; the latter being the more valuable, as, by a change of key, the nature of the communication might be kept a secret from those actually employed in making the signals.

It has been supposed that electricity might be the means of conveying intelligence, by passing given numbers of sparks through an insulated wire in given spaces of time. A gentleman of the name of Ronalds has written a small treatise on the subject; and several persons on the Continent and in England have made experiments on Galvanic or Voltaic telegraphs, by passing the stream through wires in metal pipes to the two extremities or stations, into phials of water; but there is reason to think that, ingenious as the experiments are, they are not likely ever to become practically useful. Since this was written, Professor Wheatstone has succeeded in contriving a Galvanic telegraph that works admirably, and will no doubt be applied to all the great lines of rail-road in the kingdom. It is simple in its construction, not liable to error, very portable, and carries round the margin of a circle the letters of the whole alphabet in rapid succession, so that each word is speedily conveyed to any distance.

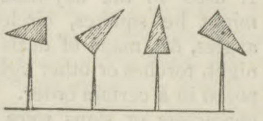
Necessity is said to be the mother of invention; she is also frequently the foster-mother, who calls forth into action, and displays the utility of, inventions abandoned by their natural parent. Both Hooke's invention and Amantons' modification were published all over Europe, the former as early as 1684; yet they were not practically applied to any useful purpose till the year 1794, when Citizen Barrere, in a report made to the Convention, ascribed the invention then in use to Citizen Chappe.

Chappe's telegraph consists of a beam of wood, moveable on a pivot at the summit of an upright post. At each of the extremities of this beam is a moveable arm, as in the figure. The different positions in which both the beam and its two arms may be placed at angles of 45° give to this telegraph considerable powers; but it is too complicated a machine not to be liable to many mistakes, unless worked by long-experienced operators.

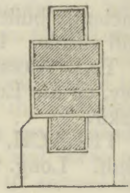


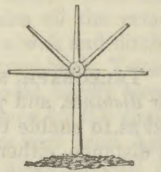
In the year 1784, Mr Lovell Edgeworth produced his plan of a numerical telegraph, claiming, at the same time, the merit of having invented a mode of distant communication as far back as 1767, by employing a common windmill, and arranging the various positions of its arms and sails so as to represent a certain number of signals arranged in numerical order.

Mr Edgeworth's telegraph consisted of four wedges or cones, moveable on four upright posts, as under, which, by their different positions, might be used either numerically or alphabetically.



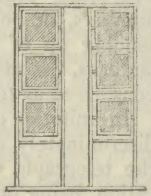
In the year 1795, when the advantages had been made evident which the French derived from M. Chappe's telegraph, the inventive faculties of our countrymen were called into action. Among other proposals, the Rev. J. Gamble produced two plans of a telegraph; the one consisting of five boards, one above the other, which, by opening and shutting singly, or according to all the combinations of which they were capable, gave a certain number of distinct signals, representing either numbers or letters, as might be deemed most expedient. The arrangement of the shutters was as in this figure. The other plan was that of five beams of wood, turning on the summit of a post, so as to form five radii of a semicircle at equal angles of 45° with each other, as in the annexed figure.





Among other projects about this time, was that of dividing a large circle into twenty-four parts, to represent the letters of the alphabet, round which a moveable radius was to traverse; then, by placing corresponding divisions, by means of wires, before the object-glass of the telescope, the coincidence of the two radii would mark out the letter meant to be designated. Of this kind, a plan by Mr Garnet approached nearest to efficiency; but, at best, could only be applied to very short distances.

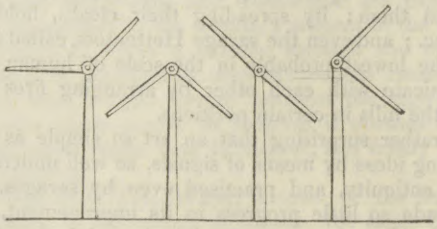
In the same year (1795) Lord George Murray presented his plan of a six-shutter telegraph to the Admiralty, which was the one adopted and made use of during the whole war, and until the year 1816, when it was changed for a simplified semaphore, which will be noticed hereafter. The annexed figure represents that of Lord George Murray.



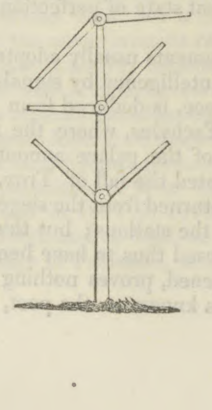
On the same principle as the radiated telegraph of Mr Gamble, but differently arranged, the French, on the commencement of the second war in 1803, erected signal-posts along the coast, to which they gave the name of semaphores, being two or three beams of wood on the same post, but turning on different pivots.

In 1807, Captain (now Colonel) Pasley published his *Polygrammatic Telegraph*, which differed only from the French semaphore in having two beams turning on one pivot on the same post, and multiplying the number of posts; which he afterwards (in 1810) changed so far as to place three sets of beams or arms, two in each set, on one post, and thus approaching still nearer to the French semaphore.

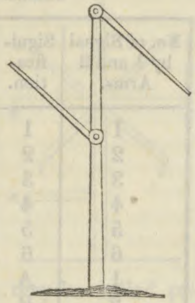
First Polygrammatic Telegraph.



Second Polygrammatic Telegraph.

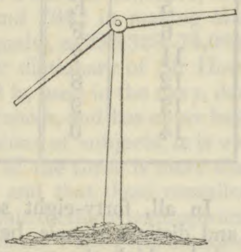


In the year 1816, Sir Home Popham, who had already introduced a new code of signals into the navy, which was admitted on all hands as a great improvement on the old system, both as regarding the number, the arrangement, and the shape of the flags, now turned his attention to the land semaphore, and proposed one on a construction of the same nature with those of M. Chappe and Colonel Pasley, but much simplified. It was, in fact, nothing more than two moveable arms on separate pivots on the same mast, as in the annexed figure.

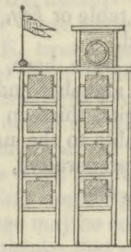


This machine, on account of its simplicity, had obviously the advantage over all others that had been proposed; and being found of sufficient power and efficiency for all required purposes, it was adopted by the Admiralty, instead of the shutter-telegraph, which had been in use since the year 1795.

Colonel Pasley, however, in 1822, still further simplified this useful machine, at the expense of sacrificing a small portion of its powers, by making the two arms revolve on the same pivot, as in this figure, to which he has given the name of the "universal telegraph."



The last, but by far the most persevering and voluminous writer on telegraphs, is Lieutenant-Colonel Macdonald, who, in 1808, published what he deems improvements in the system of telegraphic communications, both as they regard the machine itself, and the dictionary to be used with it. He not only gives the preference, but is so much attached, to the shutter machine, that he is quite indignant at its being supplanted by the semaphore; and so far from being satisfied with the powers of which a six-shutter telegraph is capable, he has extended his to no less than *thirteen* different boards, as in the annexed figure, by which he certainly gains power enough, but not without producing confusion and perplexity.



As the use of telegraphs is chiefly confined to public purposes, and more especially to convey speedy information respecting naval and military armaments and operations, the machine to be adopted, and the system of working it, ought to possess *power*, *certainty*, *simplicity*, *celerity*, and *secrecy*. The *power* of the machine, or the number of distinct combinations of its moveable parts, should be equal to the conveyance of every possible order or information, either by numbers representing the letters of the alphabet, or words, or sentences. To insure *certainty*, the moveable parts or signs should be so well and clearly defined, so wholly within the field of the telescope, and so completely removed from all ambiguity, as not to be liable to the mistaking of one signal for another; hence the advantage of the *simplicity* of the machine. And as one of the main uses of the telegraph is to convey instructions or intelligence in a speedier way than the intermediate distance can be travelled over, it is evident that *celerity* is an important quality of telegraphic communication. It is equally obvious, that if such instructions or intelligence could not be conveyed in *secrecy* from him who sent it to him who was to receive it, such a system would be highly defective and objectionable.

Bearing these observations in mind, we shall not have much difficulty in determining on the merits of the several telegraphic machines above mentioned. The choice, indeed, appears to lie between the six-shutter telegraph, so long used at the Admiralty, to communicate with the several ports; the semaphore of Sir Home Popham, which superseded it, and is now in use; and the universal telegraph of Colonel Pasley. Colonel Macdonald, who conceives the shutter telegraph as the perfection of the art, boldly asserts that "the semaphore arm of proper dimensions is not to be seen in clear weather so well as the common sized boards, and in cloudy weather by no means so well;" and consequently that, "for this climate, the boarded telegraph is in all respects more advantageous." This would be important if correct; but it is evident that the colonel is not aware of the discussion which took place on this very important part of the subject, on the first adoption of the *boarded* telegraph. Had he read the clear and decisive observations of Mr Gamble, he would scarcely have ventured upon such an assertion.

"It is a theorem in optics," says Mr Gamble, "that the apparent magnitude of an object varies nearly in the inverse ratio of its distance. Hence it follows, that the larger its dimensions, to the greater distance will it be visible. But the nature of our atmosphere, even in its most transparent state, is such as to render any calculation, grounded on this principle, extremely erroneous; and in general its density so obstructs, and its refracting powers cause such confusion in, the rays issuing from those surfaces which are not placed sufficiently distant to be distinct, that their image falling upon the retina is frequently so ill defined, as to render it difficult to determine either their figure or position; for which reasons, that which I shall term *insulation* is generally a quality more requisite to give *distinctness* to an object, than magnitude of superficial dimensions."

This is unquestionably true; but Mr Gamble illustrates his position thus: "An example of this distinctness arising from insulation cannot be more readily obtained than by taking a page of printed paper, and fixing the eye on some particular letter (as I); then retiring from it, the letter will be so confused with the surrounding ones, as not to be easily distinguished. But if the same letter (I) be printed on a plain sheet of paper, standing by itself (or *insulated*), the eye will then not only discern it at a much greater distance, but the image falling single and unencumbered upon the retina, we shall be able to determine whether it be inclined to the right or to the left, or whether it be placed horizontally on the paper."

The shutter telegraph is the printed page, and the arm of the semaphore is the letter (I) on a plain sheet of paper.

But actual experiment has completely proved the fallacy of Colonel Macdonald's assertion, and the justice of Mr Gamble's theory. Every officer serving on the line of telegraphs has stated, that at all times, and more especially in cloudy weather, the arms of the semaphore are seen much better than the boards of the telegraph ever were. Lieutenant Pace, who for many years superintended the Admiralty station, declared, that on the first day after the West Square semaphore was erected, he could clearly distinguish the positions of the arms *without a telescope*, and accurately take down any signals that could be made, which he had never been able to do, under any circumstance whatever, with the shutter telegraph. He also stated that he had frequently an open communication with the semaphore at West Square, while St Paul's was capt by a fog, which was at all times considered by him and his assistant as the conclusive sign that the boarded telegraph could not be worked. But in order to set the matter entirely at rest, the shutter telegraph on Nunhead, near Newcross, was left standing on the same hill with the new semaphore, in order to try their comparative distinctness, for a whole winter. The result was, that the semaphore was frequently distinctly visible when the boarded telegraph was so much enveloped in mist or fog, that the particular boards, shut or thrown open, could not be distinguished; and it appeared by a journal kept by this officer, that in the course of the winter, the days on which the semaphore was visible exceeded those on which the shutters could be seen by fully one third. If, then, this be the case with a six-boarded telegraph, how much more objectionable must one of twelve shutters be, which must necessarily be placed so near to each other as to make it at all times a matter of difficulty to discern at once how many, and which of them, are closed, and which open? Even in the six-shutter telegraph, one board has frequently been mistaken for the other; for it may be remarked, that such a mass of timber as is required for a shutter-telegraph is seldom free from haze.

It will probably be urged, that the arms of the semaphore, having to describe a larger circle, must be slower in their operations; but this increased slowness is so amply compensated by the ease and certainty of reading off the signals as to render any such objection of little or no weight: it may make the difference of *one second* in each signal, while the machinery by which the semaphore is worked is as simple and as little liable to be out of order as that of the boarded telegraph.

The six-shutter telegraph, it is true, has greater powers than the two-armed semaphore, and much greater than the universal semaphore of Colonel Pasley; that is to say, the number of combinations which it is capable of making without using the *stop*-signal (or signal which separates one word or one sentence from another), is much greater than in either of the other two; but *all* of them have sufficient powers, and a sufficient number of combinations, to convey with facility and despatch any communication whatsoever, and in any language, either by letters, words, or sentences. Their respective powers may be seen by the following tables of their positions.

Admiralty Six-shutter Telegraph.

In all, sixty-two separate and distinct signals, which may be made consecutively in any order, without requiring any *stop*-signal when applied to spelling. The letters of the alphabet opposite to the signals, and the numbers from 1 to 0, may be changed in every possible way.

When spelling is intended to be used, the number of changes need not, of course, exceed that of the alphabet; the rest, as in the table, may be applied to numbers; and what still remains may be made to represent *words* that are most commonly in use; as, for instance, *admiral, captain, ship of the line, frigate, arrived, sailed, harbour*, &c. in the navy; or, if military, *general, regiment, camp*, &c.

Admiralty Semaphore now in use.

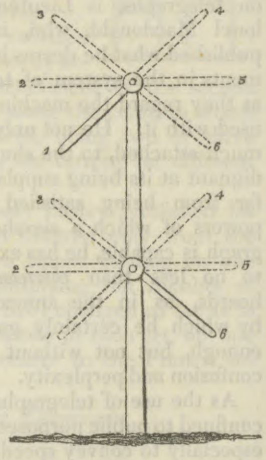
In all, forty-eight separate and distinct signals, being the whole which the two arms are capable of making, as in the annexed figure; in which the two arms actually exhibited (in black lines) represent the number 16 or H, according to the table or *key*, as above arranged.



We have here, in addition to the alphabet and the numeral digits, thirteen signs over, applicable to the names of stations, preparative, finish, stop-signals, &c.

Colonel Pasley's Universal Telegraph.

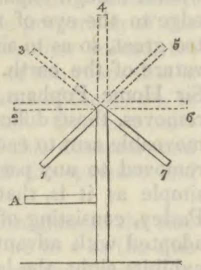
14	K	35	U		

In all, twenty-eight separate and distinct signals; containing a sufficient number for expressing the letters of the alphabet, and, consequently, for spelling any message; but not a sufficient number left to express the numeral digits by single signs. The signal No. 4 is, besides, as Colonel Pasley is aware, liable to be mistaken, it being a mere elongation of the mast, which, at a great distance, and owing to the refractive power of the atmosphere, will always be ambiguous when exhibited as a single signal. But Colonel Pasley has added a short arm, which he calls an *indicator*, as below at A; and which, when made moveable, more than compensates for this defect.

It was with a different view, however, that he has added this indicator. It was suggested to him by a captain in the navy, who had experienced the greatest inconvenience, in using Sir Home Popham's ship-semaphores, from the signal-men confounding the positions of the arms when seen in *reverse*. We apprehend no experienced signal-men could possibly make any mistake in merely changing the right hand for the left.

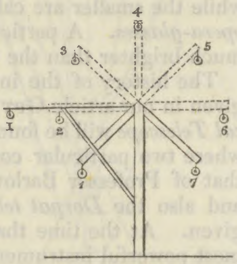


The respective powers of the three telegraphs, in making single, or what may be called primary signals, are, as appears from the tables, 62, 42, and 28. In making *two* changes, with a stop between them (that is, *three* signals), to represent a word or sentence, their powers will be as 3844, 1764, and 784; in making *three* changes (or, with the stop, *four* signals), as 238,328–74,088–21,952. Now, as the telegraphic dictionary of Sir Home Popham, which has been, and still is, used in the navy, does not exceed 13,000 words and sentences, and has never been found deficient in any of its divisions of subjects, it is evident that even the lowest power of the three is more than sufficient for all useful purposes; and that those compilers who have swelled out their telegraphic dictionaries to upwards of 100,000 (one mentioned by Colonel Pasley has extended his labours to 140,000), have made them nearly useless, by the difficulty and loss of time in finding the required phrase or sentence. We have actually seen in one telegraphic dictionary 126 pages, of three columns in each page, and sixty sentences in each column, containing upwards of 20,000 sentences (about one third of the number of words in Johnson's Dictionary), and each of these sentences beginning with the personal pronoun HE, twenty pages with IF, &c. Compared with the use of such a dictionary, spelling the sentences is infinitely preferable as to certainty, and in many cases as to celerity. Indeed we should say that the abbreviated nature of communications made by telegraph renders spelling by far the most eligible mode. In clear weather, the rapidity of working single signals, the short compass within which any message may be condensed, the impossibility of committing any mistake that cannot be immediately rectified, more than compensates for the difference of a few minutes which the use of sentences may probably save. In cloudy or foggy weather, the latter method will always be liable to mistake. If experience may be assumed as a guide, the practice at the Admiralty, of spelling all sentences, for the last thirty years, must decide in favour of that system.

In making use of the alphabetical table, much time may be saved by condensing the message into the briefest form possible, leaving out of the sentences such words as may not alter the sense, and generally the vowels of words. For instance, "*Order the Agamemnon out of harbour, and direct her to proceed to Spithead.*" To convey this message alphabetically, it would be quite enough to say, "Agmemn to Spthed." If *from Spithead into harbour*, "Agmemn nto hrbr." In spelling, too, it is very desirable, especially in our foggy climate, that the intelligence to be conveyed should be compressed as much as possible into the early part of the message. By not observing this rule, a curious mistake is said to have been made in the course of the Peninsular war. The admiral at Plymouth endeavoured to send up a message, but a fog coming on, part of it only on that day reached London. It began thus: "Wellington defeated"—and the rest was stopped by the fog: the anxiety for the remainder may readily be conceived; it came, however, complete towards the evening, and conveyed the intelligence, that "Wellington defeated the French," &c. Had the message been thus framed, "French defeated at," &c. (the word Wellington being quite superfluous), the anxiety for the particulars would have been of a very different kind. Much therefore depends, as far as celerity and certainty is concerned, on the construction of the sentence containing the intelligence to be conveyed.

The methods suggested for making use of telegraphic communications by night have not been less numerous than those for the day, though on land there are very few occasions on which they can be of the least possible use. A regiment might perhaps be ordered to move, at a moment's notice, in order to reach a particular point at a given time; or, as an extreme case, the enemy's fleet might be seen towards the close of the day in a particular quarter, which would make it desirable to have the intelligence conveyed in various directions; but no naval movement could take place during the night at any of the ports. So little useful, indeed, does a night telegraph for the navy appear to have been considered, that, with all the facility of applying lamps to the shutter-telegraph at the Admiralty, no attempt was ever made for carrying such a purpose into execution. Colonel Pasley's description of the application of his Universal Telegraph to night-signals will suffice to show one method (as good as any other, perhaps) of adapting the machine to this purpose.

"For night-signals, one lantern, called the centre-light, is fixed to the top of the post; and one lantern (I), as an indicator, is fixed to a light crane or derrick attached to the post, by night only, as under.



"These lanterns are stationary, and appear on the same level. Two other lanterns are suspended to the ends of the arms, upon fixing which a couple of weights are added to counterpoise them. Each of the two arms by day, and each of the two moveable lights by night, is capable of exhibiting the seven positions, besides position O pointing vertically downwards. The indicator serves to distinguish the low numbers 1, 2, 3, from the high numbers 7, 6, 5, in whatever direction the telegraph may be viewed."

The use of telegraphic communication, important as it may be on land, is far more so in the management of a fleet at sea. On the unfortunate result of Admiral Keppel's engagement, Dr Beatson, in his Memoirs, thus expresses himself: "The defects or impropriety of the signals having thus appeared clearly to be the true and sole cause of the miscarriage which disappointed the reasonable hopes of Britain on this critical and weighty occasion, we may be justified in observing, that if an admiral cannot command all the necessary movements of his ships by signal on the day of battle, he is not upon a footing with an enemy who possesses that advantage; and even with better ships and better men, and more experienced commanders, he may be foiled in his expectations of victory, if not defeated, from his want of the means to direct and to perform the necessary evolutions of his fleet."

In the Fighting and Sailing Instructions of the Duke of York (afterwards James II.), a certain number of signals are established for certain movements and manœuvres of the fleet, each flag having its respective object. *L'Art des Armées Navales* of le P. l'Hoste, published at Lyon in 1697, contains something like a system of signals, but so awkward and clumsy as to be of a very limited use. Indeed the best signals made use of, down to the American war, could only be considered as expedients; the *numerical plan* having never once been attempted, though Dr Hooke, De la Bourdonnois, and some others, had long before suggested it.

In 1798 a new signal-book was issued by the Admiralty, containing about four hundred sentences, for which flags were appropriated numerically, expressive of certain operations of a fleet, which were sufficiently useful as far as these sentences went; but when it became necessary to issue any order not to be found among them, the communication was obliged to be made by boats, and "a boat from each ship" was ordered. The state of the weather did not always render this practicable; and when it was, men's lives were frequently exposed to imminent risk. To remedy this inconvenience, Sir Home Popham printed at Calcutta a numerical code of naval signals, which was reprinted in England in 1803. He afterwards extended the code very considerably, which, by a recommendation of a committee of naval officers, has been adopted, and is now in general use in the navy. The only objection to this code, which more or less applies to all that have subsequently been proposed, is the great number of flags, &c., required for making numerical signals to the extent as laid down in the code in question; and which consists of nine flags, five cornettes, five triangles, and five pendants. With such a number it is next to impossible to make out, in calm weather, the figure and the colour of the flags; and equally so when in situations where, though expanded by the wind, they present only an edge to the eye of the observer, when the distance is not too great, so as to sink the hull of the ship behind the curvature of the earth. The semaphore or sea-telegraph of Sir Home Popham comes in aid of, and indeed entirely removes, those difficulties. It consists of two posts, with a moveable arm to each (see the article NAVY), and may be removed to any part of the deck; but we are not sure, simple as it is, that the Universal Telegraph of Colonel Pasley, consisting of one post and two arms, might not be adopted with advantage as a sea-telegraph. The former exhibits eight, the latter seven positions. (M.)

TELEMACHUS, the son of Ulysses and Penelope. His character and adventures belong more to poetry than to history.

TELESCOPE.[1]

TELESCOPE, an optical instrument for viewing distant objects; so named by compounding the Greek words τῆλε, *far off*, and σκοπέω, *I look at* or *contemplate.* This name is commonly appropriated to the larger sizes of the instrument, while the smaller are called *perspective glasses, spy-glasses, opera-glasses.* A particular kind, which is thought to be much brighter than the rest, is called a *night-glass.*

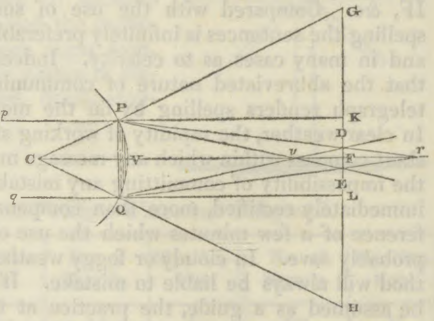
The history of the invention of the telescope has been given in our article OPTICS. The theory of the *Astronomical Telescope* will be found in ASTRONOMY (part iv. chap. 4), where two particular constructions of the instrument, viz. that of Professor Barlow and Mr Rogers, are described; and also the *Dorpat telescope*, of which a figure is there given. At the time that article was written, this was the most powerful instrument of the kind that had ever been directed to the heavens, its object-glass being $9\frac{1}{2}$ inches in diameter, and focal length about 14 feet. Now, however, the University of Cambridge possesses an instrument still more powerful, the *Northumberland Equatorial*, so called in honour of the noble duke by whom it was presented to the university in the year 1838. The object-glass of this magnificent telescope is $11\frac{1}{2}$ clear inches in diameter, and its focal length $19\frac{1}{2}$ feet. A particular description of it has been given in the eleventh volume of the Cambridge Astronomical Observations. There is another telescope of still larger dimensions in the possession of an amateur astronomer, Mr Cooper of Sligo. The diameter of the object-glass is 13·3 inches, and the focal length 21 feet 3 inches.

The general aim in the construction of a telescope is, to form, by means of mirrors or lenses, an image of the distant object, as large, as bright, and as extensive as is possible, consistently with distinctness; and then to view the image with a magnifying glass in any convenient manner. This gives us an arrangement of our subject. We shall first show the principles of construction of the object-glass or mirror, so that it shall form an image of the distant object with these qualities; and then show how to construct the magnifying glass or eye-piece, so as to preserve them unimpaired.

This indistinctness which we wish to avoid arises from two causes; the spherical figures of the refracting and reflecting surfaces, and the different refrangibility of the differently coloured rays of light. The first may be called the *spherical* and the second the *chromatic* indistinctness; and the deviations from the foci may be called the *spherical* and the *chromatic* aberrations.

The limits of a work like this will not permit us to give any more of the doctrine of aberrations than is absolutely necessary for the construction of achromatic telescopes; and we must refer the reader for a general view of the whole to Euler's Dioptrics, also to Dr Smith's Optics. We shall begin with the aberration of colour.

Fig. 1.



Let white or compounded light fall perpendicularly on the flat side PQ (fig. 1) of a plano-convex lens PVQ, whose axis is CV and vertex V. The white ray pP falling on the extremity of the lens is dispersed by refraction at the point P of the spherical surface, and the red ray goes to the point r of the axis, and the violet ray to the point v. In like manner, the white ray qQ is dispersed by refraction at Q, the red ray going to r, and the violet to v. The red ray Pr crosses the violet ray Qv in a point D, and Qr crosses Pv in a point E; and the whole light refracted and dispersed by the circumference whose diameter is PQ, passes through the circular area, whose diameter is DE. Supposing that the lens is of such a form that it would collect red rays, refracted by its whole surface in the point r, and violet in the point v; then it is evident that the whole light which occupies the surface of the lens will pass through this little circle, whose diameter is DE. Therefore white light issuing from a point so distant that the rays may be considered as parallel, will not be collected in another point or focus, but will be dispersed over the surface of that little circle, which is therefore called the *circle of chromatic dispersion;* and the radiant point will be represented by this circle. The neighbouring points are in like manner represented by circles; and these circles, encroaching on and mixing with each other, must occasion haziness or confusion, and render the picture indistinct. This indistinctness will be greater in the proportion of the number of circles which are in this manner mixed together. This will be in the proportion of the room that is for them; that is, in proportion to the area of the circle, or in the duplicate proportion of its diameter. Our first business therefore is to obtain measures of this diameter, and to mark the connection between it and the aperture and focal distance of the lens.

---

[1] Though this subject has already been partly discussed under the articles ACHROMATIC GLASSES and OPTICS, it could not be viewed as fully illustrated without a separate treatise; and the editor gladly avails himself of the late Professor Robison's article on the Telescope, which forms one of the valuable series of contributions by him to the third edition of this work.

Let i be to r as the sine of incidence in glass to the sine of refraction of the red rays; and let i be to v as the sine of incidence to the sine of refraction of the violet rays. Then we say, that when the aperture PQ is moderate, $v-r : v+r-2i = \mathrm{DE} : \mathrm{PQ}$ very nearly.

For let DE, which is evidently perpendicular to Vr, meet the parallel incident rays in K and L and the radii of the spherical surface in G and H. It is plain that GPK is equal to the angle of incidence on the posterior or spherical surface of the lens; and GPr and GPv are the angles of the refraction of the red and the violet rays; and that GK, GD, and GE, are very nearly as the sines of those angles, because the angles are supposed to be small. Therefore $\mathrm{DE} : \mathrm{KD} = v-r : r-i$; and, by doubling the consequents, $\mathrm{DE} : 2\mathrm{KD} = v-r : 2r-2i$. Also $\mathrm{DE} : 2\mathrm{KD} + \mathrm{DE} = v-r : 2r-2i+v-r = v-r : r+v-2i$. But $2\mathrm{KD}+\mathrm{DE}$ is equal to KL or PQ. Therefore we have $\mathrm{DE} : \mathrm{PQ} = v-r : r+v-2i$. *Q. E. D.*

Cor. 1. Sir Isaac Newton found, that in common glass the sines of refraction of the red and violet rays were 77 and 78 where the sine of incidence was 50. Hence $v-r$ is to $v+r-2i$ as 1 to 55; and the diameter of the smallest circle of dispersion is $\frac{1}{55}$th part of that of the lens.

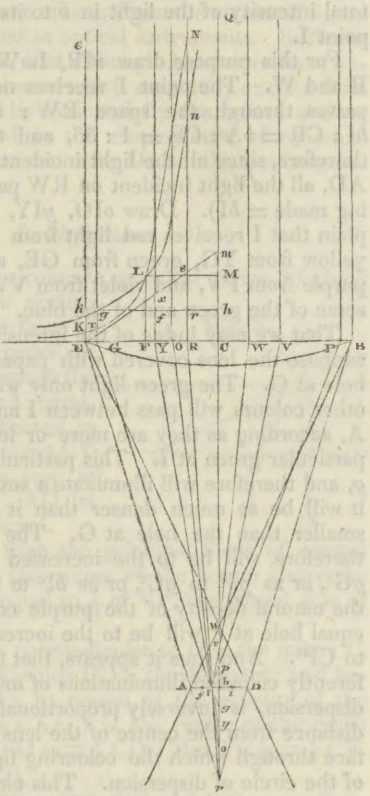
2. In like manner may be determined the circle of dispersion that will comprehend the rays of any particular colour or set of colours. Thus all the orange and yellow will pass through a circle whose diameter is $\frac{1}{200}$th of that of the lens.

3. In different surfaces, or plano-convex lenses, the angles of aberration rPv are as the breadth PQ directly, and as the focal distance VF inversely; because any angle DPE is as its subtense DE directly and radius DP inversely. —We call VF the focal distance, because at this distance, or at the point F, the light is most of all constipated. If we examine the focal distance by holding the lens to the sun, we judge it to be where the light is drawn into the smallest spot.

When we reflect that a lens of $5\frac{1}{2}$ inches in diameter has a circle of dispersion $\frac{1}{10}$th of an inch in diameter, we are surprised that it produces any picture of an object that can be distinguished. We should not expect greater distinctness from such a lens than would be produced in a camera obscura without a lens, by simply admitting the light through a hole of $\frac{1}{10}$th of an inch in diameter. This, we know, would be very hazy and confused. But when we remark the superior vivacity of the yellow and orange light in comparison with the rest, we may believe that the effect produced by the confusion of the other colours will be much less sensible. But a stronger reason is, that the light is much denser in the middle of the circle of dispersion, and is exceedingly faint towards the margin. This, however, must not be taken for granted; and we must know distinctly the manner in which the light of different colours is distributed over the circle of chromatic dispersion, before we pretend to pronounce on the immense difference between the indistinctness arising from colour and that arising from the spherical figure. We think this the more necessary, seeing that the illustrious discoverer of the chromatic aberration has made a great mistake in the comparison, because he did not consider the distribution of the light in the circle of spherical dispersion. It is therefore proper to investigate the chromatic distribution of the light, and we shall then see that the superiority of the reflecting telescope is incomparably less than Newton imagined it to be.

Therefore let EB (fig. 2) represent a plano-convex lens, of which C is the centre and Cr the axis. Let us suppose it to have no spherical aberration, but to collect rays occupying its whole surface to single points in the axis. Let a beam of white or compounded light fall perpendicularly on its plane surface. The rays will be so refracted by its curved surface, that the extreme red rays will be collected at r, the extreme violet rays at w, and those of intermediate refrangibility at intermediate points o, y, g, b, p, v, of the line rw, which is nearly $\frac{1}{28}$th of rC. The extreme red and violet rays will cross each other at A and D; and AD will be a section or diameter of the circle of chromatic dispersion, and will be about $\frac{1}{55}$th of EB. We may suppose wr to be bisected in b, because wb is to br very nearly in the ratio of equality (for $rb : r\mathrm{C} = b\mathrm{A} : c\mathrm{E} = b\mathrm{A} : c\mathrm{B} = wb : w\mathrm{C}$). The line rw will be a kind of prismatic spectrum, red from r to o, orange-coloured from o to y, yellow from y to g, green from g to b, blue from b to p, purple from p to v, and violet from v to w.

Fig. 2.



The light in its compound state must be supposed uniformly dense as it falls upon the lens; and the same must be said of the rays of any particular colour. Newton supposes also, that when a white ray, such as eE, is dispersed into its component coloured rays by refraction at E, it is uniformly spread over the angle DEA. This supposition is indeed gratuitous; but we have no argument to the contrary, and may therefore consider it as just. The consequence is, that each point w, v, p, b, &c. of the spectrum is not only equally luminous, but also illuminates uniformly its corresponding portion of AD; that is to say, the coating (so to term it) of any particular colour, such as purple, from the point p, is uniformly dense in every part of AD on which it falls. In like manner, the colouring of yellow, intercepted by a part of AD in its passage to the point y, is uniformly dense in all its parts. But the density of the different colours in AD is extremely different; for, since the radiation in w is equally dense with that in p, the density of the violet colouring, which radiates from w, and is spread over the whole of AD, must be much less than the density of the purple colouring, which radiates from p, and occupies only a part of AD round the circle b. These densities must be very nearly in the inverse proportion of wb^2 to pb^2.

Hence we see that the central point *b* will be very intensely illuminated by the blue radiating from *pb*, and the green intercepted from *bg*. It will be more faintly illuminated by the purple radiating from *vp*, and the yellow intercepted from *gy*; and still more faintly by the violet from *wv*, and the orange and red intercepted from *yr*. The whole colouring will be a white, tending a little to yellowness. The accurate proportion of these colourings may be computed from our knowledge of the position of the points *o*, *y*, *g*, &c. But this is of little moment. It is of more consequence to be able to determine the proportion of the total intensity of the light in *b* to its intensity in any other point I.

For this purpose draw *r*IR, I*w*W, meeting the lens in R and W. The point I receives none of the light which passes through the space RW; for it is evident that *b*I : CR = *b*A : CE = 1 : 55, and that CR = CW; and therefore, since all the light incident on EB passes through AD, all the light incident on RW passes through I*i* (*bi* being made = *b*I). Draw *o*IO, *y*IY, *g*IG, I*p*P, I*v*V. It is plain that I receives red light from RO, orange from OY, yellow from YG, green from GE, a little blue from BP, purple from PV, and violet from VW. It therefore wants some of the green and of the blue.

That we may judge of the intensity of these colours at I, suppose the lens covered with paper pierced with a small hole at G. The green light only will pass through I; the other colours will pass between I and *b*, or between I and A, according as they are more or less refrangible than the particular green at I. This particular colour converges to *g*, and therefore will illuminate a small spot round I, where it will be as much denser than it is at G as this spot is smaller than the hole at G. The natural density at G, therefore, will be to the increased density at I, as $g\mathrm{I}^2$ to $g\mathrm{G}^2$, or as gb^2 to $g\mathrm{C}^2$, or as $b\mathrm{I}^2$ to CG^2. In like manner, the natural density of the purple coming to I through an equal hole at P will be to the increased density at I as $b\mathrm{I}^2$ to CP^2. And thus it appears, that the intensity of the differently coloured illuminations of *any* point of the circle of dispersion, is inversely proportional to the square of the distance from the centre of the lens to the point of its surface through which the colouring light comes to this point of the circle of dispersion. This circumstance will give us a very easy, and, we think, an elegant solution of the question.

Bisect CE in F, and draw FL perpendicular to CE, making it equal to CF. Through the point L describe the hyperbola KLN of the second order, that is, having the ordinates EK, FL, RN, &c. inversely proportional to the squares of the abscissæ CE, CF, CR, &c.; so that FL : RN $= \frac{1}{\mathrm{CF}^2} : \frac{1}{\mathrm{CR}^2}$, or $= \mathrm{CR}^2 : \mathrm{CF}^2$, &c. It is evident that these ordinates are proportional to the densities of the severally coloured lights which go from them to any points whatever of the circle of dispersion.

Now the total density of the light at I depends both on the density of each particular colour and on the number of colours which fall on it. The ordinates of this hyperbola determine the first; and the space ER measures the number of colours which fall on I, because it receives light from the whole of ER, and of its equal BW. Therefore, if ordinates be drawn from any point of ER, their sum will be as the whole light which goes to I; that is, the total density of the light at I will be proportional to the area NREK. Now it is known that CE · EK is equal to the infinitely extended area lying beyond EK; and CR · RN is equal to the infinitely extended area lying beyond RN. Therefore the area NREK is equal to CR · RN — CE · EK. But RN and EK are respectively equal to $\frac{\mathrm{CF}^3}{\mathrm{CR}^2}$ and $\frac{\mathrm{CF}^3}{\mathrm{CE}^2}$. Therefore the density at I is proportional to $\mathrm{CF}^3 \cdot \left(\frac{\mathrm{CR}}{\mathrm{CR}^2} - \frac{\mathrm{CE}}{\mathrm{CF}^2}\right)$ $= \mathrm{CF}^3 \cdot \left(\frac{1}{\mathrm{CR}} - \frac{1}{\mathrm{CE}}\right) = \mathrm{CF}^3 \cdot \frac{\mathrm{CE}-\mathrm{CR}}{\mathrm{CE}\cdot\mathrm{CR}} = \mathrm{CF}^3 \cdot \frac{\mathrm{ER}}{\mathrm{CE}\cdot\mathrm{CR}}$ $= \frac{\mathrm{CF}^3}{\mathrm{CE}} \cdot \frac{\mathrm{ER}}{\mathrm{CR}}$. But because CF is $\frac{1}{2}$ of CE, $\frac{\mathrm{CF}^3}{\mathrm{CE}}$ is $= \frac{\mathrm{CF}^3}{2\,\mathrm{CF}}$ $= \frac{\mathrm{CF}^2}{2}$, a constant quantity. Therefore the density of the light at I is proportional to $\frac{\mathrm{ER}}{\mathrm{CR}}$, or to $\frac{\mathrm{AI}}{b\mathrm{I}}$, because the points R and I are similarly situated in EC and A*b*.

Farther, if the semi-aperture CE of the lens be called 1, $\frac{\mathrm{CF}^2}{2}$ is $= \frac{1}{8}$, and the density at I is $= \frac{\mathrm{AI}}{8\,b\mathrm{I}}$.

Here it is proper to observe, that since the point R has the same situation in the diameter EB that the point I has in the diameter AD of the circle of dispersion, the circle described on EB may be conceived as the magnified representation of the circle of dispersion. The point F, for instance, represents the point *f* in the circle of dispersion, which bisects the radius *b*A; and *f* receives no light from any part of the lens which is nearer the centre than F, being illuminated only by the light which comes through EF, and its opposite BF′. The same may be said of every other point.

In like manner, the density of the light in *f*, the middle between *b* and A, is measured by $\frac{\mathrm{EF}}{\mathrm{CF}}$, which is $= \frac{\mathrm{EF}}{\mathrm{EF}}$, or 1. This makes the density at this point a proper standard of comparison. The density there is to the density at I as 1 to $\frac{\mathrm{AI}}{b\mathrm{I}}$, or as *b*I to AI; and this is the simplest mode of comparison. The density half way from the centre of the circle of dispersion, is to the density at any point I as *b*I to AI.

Lastly, through L describe the common rectangular hyperbola *k*L*n*, meeting the ordinates of the former in *k*, L, and *n*; and draw *kh* parallel to EC, cutting the ordinates in *g*, *f*, *r*, &c. Then CR : CE = E*k* : R*n*, and CR : CE — CR = E*k* : R*n* — E*k*, or CR : RE = E*k* : *rn*, and *b*I : IA = E*k* : *rn*. And thus we have a very simple expression of the density in any point of the circle of dispersion. Let the point be anywhere, as at I. Divide the lens in R as AD is divided in I, and then *rn* is as the density in I.

These two measures were given by Newton; the first in his treatise *de Mundi Systemate*, and the last in his Optics, but both without demonstration.

If the hyperbola *k*L*n* be made to revolve round the axis CQ, it will generate a solid spindle, which will measure the whole quantity of light which passes through different portions of the circle of dispersion. Thus the solid produced by the revolution of L*kf* will measure all the light which occupies the outer part of the circle of dispersion lying without the middle of the radius. This space is $\frac{3}{4}$ths of the whole circle; but the quantity of light is but $\frac{1}{4}$th of the whole.

A fully more simple expression of the whole quantity of light passing through different portions of the circle of chromatic dispersion may now be obtained as follows:

It has been demonstrated, that the density of the light at I is as $\frac{\mathrm{AI}}{b\mathrm{I}}$, or as $\frac{\mathrm{ER}}{\mathrm{CR}}$. Suppose the figure to turn round the axis: the points I and R describe circumferences of circles; and the whole light passing through this circumference is as the circumference, or as the radius and as the density jointly. It is therefore as $\frac{ER}{CR}\cdot CR$, that is, as ER. Draw any straight line Em, cutting RN in s, and any other ordinate FL in xRs. The whole light which illuminates the circumference described by I is to the whole light which illuminates the centre b as ER to EC, or as Rs to Cm. In like manner, the whole light which illuminates the circumference described by the point f in the circle of dispersion, is to the whole light which illuminates the centre b as Fx to Cm. The lines Cm, Rs, Fx, are therefore proportional to the whole light which illuminates the corresponding circumferences in the circle of dispersion. Therefore the whole light which falls on the circle whose radius is bI, will be represented by the trapezium in CRs; and the whole light which falls on the ring described by IA, will be represented by the triangle EsR; and so of any other portions.

By considering the figure, we see that the distribution of the light is exceedingly unequal. Round the margin it has no sensible density; while its density in the very centre is incomparably greater than in any other point, being expressed by the asymptote of a hyperbola. Also the circle described with the radius $\frac{Ab}{2}$ contains $\frac{3}{4}$ths of the whole light. No wonder, then, that the confusion caused by the mixture of these circles of dispersion is less than one should expect; besides, it is evident that the most lively or impressive colours occupy the middle of the spectrum, and are there much denser than the rest. The margin is covered with an illumination of deep red and violet, neither of which colours is brilliant. The margin will be of a dark claret colour. The centre revives all the colours, but in a proportion of intensity greatly different from that in the common prismatic spectrum, because the radiant points L, p, b, g, &c. by which it is illuminated, are at such different distances from it. It will be white; but, we apprehend, not a pure white, being greatly overcharged with the middle colours.

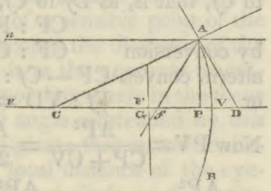
These considerations show that the coloured fringes which are observed to border very luminous objects seen on a dark ground through optical instruments, do not proceed from the object-glass of a telescope or microscope, but from an improper construction of the eye-glasses. The chromatic dispersions would produce fringes of a different colour when they produce any at all, and the colours would be differently disposed. But this dispersion by the object-glass can hardly produce any fringes: its effect is a general and almost uniform mixture of circles all over the field, which produces an uniform haziness, as if the object were viewed at an improper distance, or out of its focus, as we vulgarly express it.

We may at present form a good guess at the limit which this cause puts to the performance of a telescope. A point of a very distant object is represented, in the picture formed by the object-glass, by a little circle, whose diameter is at least $\frac{1}{300}$th of the aperture of the object-glass, making a very full allowance for the superior brilliancy and density of the central light. We look at this picture with a magnifying eye-glass. This magnifies the picture of the point. If it amplify it to such a degree as to make it an object individually distinguishable, the confusion is then sensible. Now this can be computed. An object subtending one minute of a degree is distinguished by the dullest eye, even although it be a dark object on a bright ground. Let us therefore suppose a telescope, the object-glass of which is of six feet focal distance, and one inch aperture. The diameter of the circle of chromatic dispersion will be $\frac{1}{300}$th of an inch, which subtends at the centre of the object-glass an angle of about nine seconds and a half. This, when magnified six times by an eye-glass, would become a distinguishable object; and a telescope of this length would be indistinct if it magnified more than six times, if a point were thus spread out into a spot of uniform intensity. But the spot is much less intense about its margin. It is found experimentally that a piece of engraving, having fine cross hatches, is not sensibly indistinct till brought so far from the limits of perfectly distinct vision, that this indistinctness amounts to 6′ or 5′ in breadth. Therefore such a telescope will be sensibly distinct when it magnifies thirty-six times; and this is very agreeable to experience.

We come, in the second place, to the more arduous task of ascertaining the error arising from the spherical figure of the surfaces employed in optical instruments. Suffice it to say, before we begin, that although geometers have exhibited other forms of lenses which are totally exempt from this error, they cannot be executed by the artist; and we are therefore restricted to the employment of spherical surfaces. We shall set out with Dr Smith's fundamental theorem.

1. *In Reflections.*

Fig. 3.



Let AVB (fig 3) be a concave spherical mirror, of which C is the centre, V the vertex, CV the axis, and F the focus of an infinitely slender pencil of parallel rays passing through the centre. Let the ray aA, parallel to the axis, be reflected in AG, crossing the central ray CV in f. Let AP be the sine of the semi-aperture AV, AD its tangent, and CD its secant.

The aberration Ff from the principal focus of central rays is equal to $\frac{1}{2}$ VD, the excess of the secant above the radius, or very nearly equal to $\frac{1}{2}$ of VP, the versed sine of the semi-aperture.

For, because AD is perpendicular to CA, the points C, A, D, are in a circle, of which CD is the diameter; and because Af is equal to Cf, by reason of the equality of the angles fAC, fCA, and CAa, f is the centre of the circle through C, A, D, and fD is $= \frac{1}{2}$ CD. But FC is $= \frac{1}{2}$ CV. Therefore Ff is $\frac{1}{2}$ of VD.

But because DV : VP = DC : VC, and DC is very little greater than VC when the aperture AB is moderate, DV is very little greater than VP, and Ff is very nearly equal to $\frac{1}{2}$ of VP.

Cor. 1. The longitudinal aberration Ff is $=\frac{AV^2}{4CV}$, for PV is very nearly $=\frac{AV^2}{2CV}$.

Cor. 2. The lateral aberration FG is $=\frac{AV^3}{2CV^2}$. For FG : Ff = AP : Pf = AV : $\frac{1}{2}$ CV nearly, and therefore $FG=\frac{AV^3}{4CV}\cdot\frac{2}{CV}=\frac{AV^3}{2CV^2}$.

2. *In Refractions.*

Let AVB (fig. 4 or 5) be a spherical surface separating

Fig. 4.

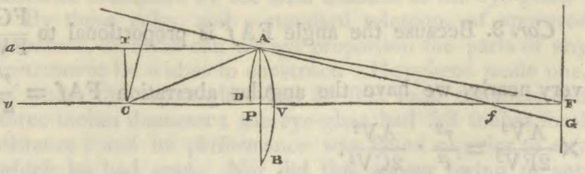


Fig. 5.

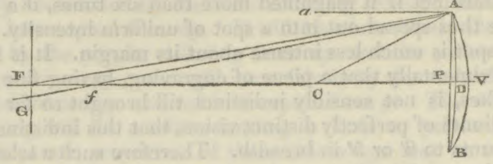


two refracting substances, C the centre, V the vertex, AV the semi-aperture, AP its sine, PV its versed sine, and F the focus of parallel rays infinitely near to the axis. Let the extreme ray aA, parallel to the axis, be refracted into AG, crossing CF in f, which is therefore the focus of extreme parallel rays.

The rectangle of the sine of incidence, by the difference of the sines of incidence and refraction, is to the square of the sine of refraction, as the versed sine of the semi-aperture is to the longitudinal aberration of the extreme rays.

Call the sine of incidence i, the sine of refraction r, and their difference d.

Join CA, and about the centre f describe the arch AD.

The angle ACV is equal to the angle of incidence, and CAf is the angle of refraction. Then, since the sine of incidence is to the sine of refraction as VF to CF, or as Af to Cf, that is, as Df to Cf, we have

$$\mathrm{CF} : \mathrm{FV} = \mathrm{C}f : f\mathrm{D},$$

by conversion $\mathrm{CF} : \mathrm{CV} = \mathrm{C}f : \mathrm{CD},$

altern. conver. $\mathrm{CF} - \mathrm{C}f : \mathrm{CV} - \mathrm{CD} = \mathrm{CF} : \mathrm{CV}$

or $\mathrm{F}f : \mathrm{VD} = \mathrm{CF} : \mathrm{CV} = r : d.$

Now $\mathrm{PV} = \dfrac{\mathrm{AP}^2}{\mathrm{CP}+\mathrm{CV}} = \dfrac{\mathrm{AP}^2}{2\mathrm{CV}}$ nearly, and $\mathrm{PD} = \dfrac{\mathrm{AP}^2}{f\mathrm{P}+f\mathrm{V}} = \dfrac{\mathrm{AP}^2}{2f\mathrm{V}}$ nearly, $= \dfrac{\mathrm{AP}^2}{2\mathrm{FV}}$ nearly. Therefore $\mathrm{PV} : \mathrm{PD} = \mathrm{FV} : \mathrm{CV}$, and $\mathrm{DV} : \mathrm{PV} = \mathrm{CF} : \mathrm{FV}$ nearly.

We had above $\mathrm{F}f : \mathrm{VD} = r : d,$

and now $\mathrm{VD} : \mathrm{PV} = \mathrm{CF} : \mathrm{FV} = r : i;$

therefore $\mathrm{F}f : \mathrm{PV} = r^2 : di,$

and $\mathrm{F}f = \dfrac{r^2}{di} \cdot \mathrm{PV}$. *Q. E. D.*

The aberration will be different according as the refraction is made towards or from the perpendicular; that is, according as r is less or greater than i. They are in the ratio of $\dfrac{r^2}{di}$ to $\dfrac{i^2}{dr}$, or of r^3 to i^3. The aberration therefore is always much diminished when the refraction is made from a rare into a dense medium. The proportion of the sines for air and glass is nearly that of 3 to 2. When the light is refracted into the glass, the aberration is nearly $\frac{4}{3}$ of PV; and when the light passes out of glass into air, it is about $\frac{9}{2}$ of PV.

Cor. 1. $\mathrm{F}f = \dfrac{r^2}{di} \cdot \dfrac{\mathrm{AP}^2}{2\mathrm{CV}}$ nearly, and it is also $= \dfrac{r^2}{d^2} \cdot \dfrac{\mathrm{AP}^2}{2\mathrm{FV}}$, because $\mathrm{PV} = \dfrac{\mathrm{AP}^2}{2\mathrm{CV}}$ nearly, and $i : d = \mathrm{FV} : \mathrm{CV}$.

Cor. 2. Because $f\mathrm{P} : \mathrm{PA} = \mathrm{F}f : \mathrm{FG}$
or $\mathrm{FV} : \mathrm{AV} = \mathrm{F}f : \mathrm{FG}$ nearly,

we have FG, the lateral aberration, $= \mathrm{F}f \times \dfrac{\mathrm{AV}}{\mathrm{FV}} = \dfrac{r^2}{d^2} \cdot \dfrac{\mathrm{AV}^3}{2\mathrm{FV}^2} = \dfrac{r^2}{i^2} \cdot \dfrac{\mathrm{AV}^3}{2\mathrm{CV}^2}$.

Cor. 3. Because the angle FAf is proportional to $\dfrac{\mathrm{FG}}{\mathrm{FV}}$ very nearly, we have the angular aberration $\mathrm{FA}f = \dfrac{r^2}{d^2} \times \dfrac{\mathrm{AV}^3}{2\mathrm{FV}^3} = \dfrac{r^2}{i^2} \cdot \dfrac{\mathrm{AV}^2}{2\mathrm{CV}^3}$.

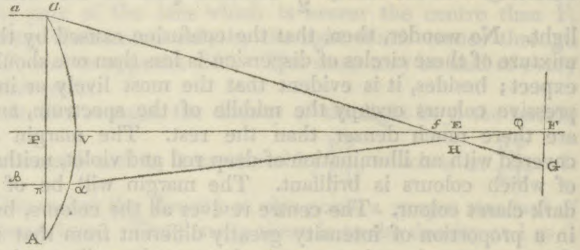
In general, the longitudinal aberrations from the focus of central parallel rays are as the squares of the apertures directly, and as the focal distances inversely; and the lateral aberrations are as the cubes of the apertures directly, and the squares of the focal distances inversely; and the angular aberrations are as the cubes of the aperture directly, and the cubes of the focal distances inversely.

The reader must have observed, that to simplify the investigation, some small errors are admitted. PV and PD are not in the exact proportion that we assumed them, nor is Df equal to FV. But in the small apertures which suffice for optical instruments, these errors may be disregarded.

This spherical aberration produces an indistinctness of vision, in the same manner as the chromatic aberration does, viz. by spreading out every mathematical point of the object into a little spot in its picture; which spots, by mixing with each other, confuse the whole. We must now determine the diameter of the circle of diffusion, as we did in the case of chromatic dispersion.

Let a ray $\beta\alpha$ (fig. 6) be refracted on the other side of the axis, into αHφ, cutting afG in H, and draw the perpendicular EH. Put $\mathrm{AV} = a$, $\alpha\mathrm{V} = \alpha$, V$f$ (or VF or Vφ, which in this comparison may be taken as equal) $= f$, $\mathrm{F}f = b$, and $f\mathrm{E} = x$.

Fig. 6.



$\mathrm{AV}^2 : \alpha\mathrm{V}^2 = \mathrm{F}f : \mathrm{F}\varphi$ (already demonstrated), and $\mathrm{F}\varphi = \dfrac{\alpha^2}{a^2}b$, and $\mathrm{F}f - \mathrm{F}\varphi$ (or $f\varphi$) $= b - \dfrac{\alpha^2}{a^2}b = \dfrac{a^2b - \alpha^2b}{a^2} = \dfrac{b}{a^2}(a^2 - \alpha^2) = \dfrac{b}{a^2}(a+\alpha)(a-\alpha)$. Also $\mathrm{P}f : \mathrm{PA} = f\mathrm{E} : \mathrm{EH}$, or $f : a = x : \dfrac{ax}{f} = \mathrm{EH}$. And $\mathrm{P}\pi : \mathrm{P}\varphi = \mathrm{EH} : \mathrm{E}\varphi$ or $\alpha : f = \dfrac{ax}{f} : \dfrac{ax}{\alpha} = \mathrm{E}\varphi$. Therefore $f\varphi = \dfrac{ax}{\alpha} + x = \dfrac{ax + \alpha x}{\alpha} = \dfrac{x}{\alpha}(a+\alpha)$. Therefore $\dfrac{x}{\alpha} \cdot (a+\alpha) = \dfrac{b}{a^2}(a+\alpha)(a-\alpha)$, and $\dfrac{x}{\alpha} = \dfrac{b}{a^2}(a-\alpha)$, and $x = \dfrac{b}{a^2}\alpha(a-\alpha)$. Therefore x is greatest when $\alpha(a-\alpha)$ is greatest; that is, when $\alpha = \frac{1}{2}a$. Therefore EH is greatest when Pπ is equal to the half of AP. When this is the case, we have at the same time $\dfrac{b}{a^2} \cdot \alpha(a-\alpha) = \dfrac{b}{a^2} \cdot \frac{1}{4}a^2$, and $x = \frac{1}{4}b$, or $\mathrm{EH} = \frac{1}{4}\mathrm{FG}$. That is, the diameter of the circle of aberration through which the whole of the refracted light must pass, is $\frac{1}{4}$ of the diameter of the circle of aberration at the focus of parallel central rays. In the chromatic aberration it was $\frac{1}{2}$; so that in this respect the spherical aberration does not create so great confusion as the chromatic.

We are now able to compare them, since we have the measure of both the circles of aberration.

It has not been found possible to give more than four inches of aperture to an object-glass of 100 feet focal distance, so as to preserve sufficient distinctness. If we compute the diameter of the circle EH corresponding to this aperture, we shall find it not much to exceed $\frac{1}{120,000}$ of an inch. If we restrict the circle of chromatic dispersion to $\frac{1}{250}$ of the aperture, which is hardly the fifth part of the whole dispersion in it, it is $\frac{1}{62\frac{1}{2}}$ of an inch, and is about 1900 times greater than the other.

The circle of spherical aberration of a plano-convex lens, with the plane side next the distant object, is equal to the circle of chromatic dispersion when the semi-aperture is about 15°; for we saw formerly that EH is $\frac{1}{4}$ of FG, and that FG is $=\frac{r^2}{i^2}\frac{AP^3}{2AC^2}$, and therefore $EG=\frac{r^2}{i^2}\cdot\frac{AP^3}{8AC^2}$. This being made $=\frac{AP}{55}$, gives us $AP=\sqrt{\frac{8i^2AC^2}{55r^2}}$, which is nearly $\frac{AC}{4}$, and corresponds to an aperture of 30° diameter, if r be to i as 3 to 2.

Sir Isaac Newton was therefore well entitled to say, that it was quite needless to attempt figures which should have less aberration than spherical ones, while the confusion produced by the chromatic dispersion remained uncorrected. Since the indistinctness is as the squares of the diameters of the circles of aberration, the disproportion is quite beyond our imagination, even when Newton has made such a liberal allowance to the chromatic dispersion. But it must be acknowledged, that he has not attended to the distribution of the light in the circle of spherical aberration, and has hastily supposed it to be like the distribution of the coloured light, indefinitely rare in the margin, and denser in the centre.

Boscovich has shown that the light in the margin of the circle of spherical aberration, instead of being incomparably rarer than in the spaces between it and the centre, is incomparably denser. The indistinctness therefore produced by the intersection of these luminous circumferences is vastly great, and increases the whole indistinctness exceedingly. By a gross calculation which we made, it appears to be increased at least 500 times. The proportional indistinctness, therefore, instead of being 1900^2 to 1, is only $\frac{1900^2}{500}$, or nearly 7220 to 1; a proportion still sufficiently great to warrant Newton's preference of the reflecting telescope of his invention. And we may now observe, that the reflecting telescope has even a great advantage over a refracting one of the same focal distance, with respect to its spherical aberration: For we have seen (*Cor.* 2) that the lateral aberration is $\frac{r^2}{i^2}\frac{AV^3}{2CV^2}$. This for a plano-convex glass is nearly $\frac{9}{4}\frac{AV^3}{2CV^2}$, and the diameter of the circle of aberration is one fourth of this, or $\frac{9}{16}\cdot\frac{AV^3}{2CV^2}$. In like manner, the lateral aberration of a concave mirror is $\frac{AV^3}{2CV^2}$; and the diameter of the circle of dispersion is $\frac{AV^3}{8CV^2}$; and therefore, if the surfaces were portions of the same sphere, the diameter of the circle of aberration of refracted rays would be to that of the circle of aberration of reflected rays as $\frac{9}{16}$ to $\frac{1}{4}$, or as 9 to 4. But when the refracting and reflecting surfaces, in the position here considered, have the same focal distance, the radius of the refracting surface is four times that of the reflecting surface. The proportion of the diameters of the circles of spherical aberration is that of 9×4^2 to 4, or of 144 to 4, or 36 to 1. The distinctness therefore of the reflector is 36×36, or 1296 times greater than that of a plano-convex lens (placed with the plane side next the distant object) of the same breadth and focal distance, and will therefore admit of a much greater magnifying power. This comparison is indeed made in circumstances most favourable to the reflector, because this is the very worst position of a plano-convex lens. But we have not as yet learned the aberration in any other position. In another position the refraction and consequent aberration of both surfaces are complicated.

Before we proceed to the consideration of this very difficult subject, we may deduce, from what has been already demonstrated, several general rules and maxims in the construction of telescopes, which will explain (to such readers as do not wish to enter more deeply into the subject) and justify the proportion which long practice of the best artists has sanctioned.

Indistinctness proceeds from the commixture of the circles of aberration on the retina of the eye: for any one *sensible* point of the retina, being the centre of a circle of aberration, will at once be affected by the admixture of the rays of as many different pencils of light as there are sensible points in the area of that circle, and will convey to the mind a mixed sensation of as many visible points of the object. This number will be as the area of the circle of aberrations, whatever be the size of a sensible point of the retina. Now in vision with telescopes the diameter of the circle of aberration on the retina is as the *apparent* magnitude of the diameter of the corresponding circle in the focus of the eye-glass; that is, as the angle subtended by this diameter at the centre of the eye-glass; that is, as the diameter itself directly, and as the focal distance of the eye-glass inversely. And the area of that circle on the retina is as the area of the circle on the focus of the eye-glass directly, and as the square of the focal distance of the eye-glass inversely. And this is the measure of the apparent indistinctness.

Cor. In all sorts of telescopes, and also in compound microscopes, an object is seen equally distinct when the focal distances of the eye-glasses are proportional to the diameters of the circles of aberration in the focus of the object-glass.

Here we do not consider the trifling alteration which well-constructed eye-glasses may add to the indistinctness of the first image.

In refracting telescopes, the apparent indistinctness is as the area of the object-glass directly, and as the square of the focal distance of the eye-glass inversely. For it has been shown, that the area of the circle of dispersion is as the area of the object-glass, and that the spherical aberration is insignificant when compared with this.

Therefore, to make reflecting telescopes equally distinct, the diameter of the object-glass must be proportional to the focal distance of the eye-glass.

But in reflecting telescopes, the indistinctness is as the sixth power of the aperture of the object-glass directly, and as the fourth power of the focal distance of the object-glass and square of the focal distance of the eye-glass inversely. This is evident from the dimensions of the circle of aberration, which was found proportional to $\frac{AV^3}{CV^2}$.

Therefore, to have them equally distinct, the cubes of the apertures must be proportional to the squares of the focal distance multiplied by the focal distance of the eye-glass.

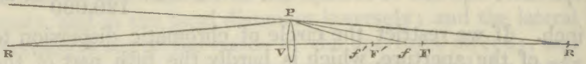
By these rules, and a standard telescope of approved goodness, an artist can always proportion the parts of any instrument he wishes to construct. Huyghens made one, of which the object-glass had 30 feet focal distance, and three inches diameter; the eye-glass had 3·3 inches focal distance; and its performance was found superior to any which he had seen. Nor did this appear owing to any chance goodness of the object-glass, because he found others equally good which were constructed on similar proportions. This has therefore been adopted as a standard.

It does not at first appear how there can be any difficulty in this matter, because we can always diminish the aperture of the object-glass or speculum, till the circle of aberration is as small as we please. But by diminishing this aperture, we diminish the light in the duplicate ratio of the aperture. Whatever be the aperture, the brightness is diminished by the magnifying power, which spreads the light over a greater surface in the bottom of the eye. The apparent brightness must be as the square of the aperture of the telescope directly, and the square of the amplification of the diameter of an object inversely. Objects therefore will be seen equally bright if the apertures of the telescopes be as the focal distances of the object-glasses directly, and the focal distances of the single eye-glass (or eye-glass equivalent to the eye-piece) inversely. Therefore, to have telescopes equally distinct and equally bright, we must combine these proportions with the former. It is needless to go farther into this subject, because the construction of refracting telescopes has been so materially changed by the correction of the chromatic aberration, that there can hardly be given any proportion between the object-glass and eye-glasses. Every thing now depends on the degree in which we can correct the aberrations of the object-glass. We have been able so far to diminish the chromatic aberration, that we can give very great apertures without its becoming sensible. But this is attended with so great an increase of the aberration of figure, that this last becomes a sensible quality. A lens which has 30° for its semi-aperture, has a circle of aberration equal to its chromatic aberration. Fortunately we can derive from the very method of contrary refractions, which we employ for removing the chromatic aberrations, a correction of the other. For this contrivance we are also indebted to the illustrious Newton.

We call this Newton's contrivance, because he was the first who proposed a construction of an object-glass in which the aberration was corrected by the contrary aberrations of glass and water.

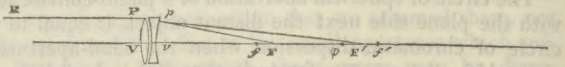
Huyghens had indeed supposed, that our all-wise Creator had employed in the eyes of animals many refractions in place of one, in order to make the vision more distinct; and the invidious detractors from Newton's fame have catched at this vague conjecture as an indication of his knowledge of the possibility of destroying the aberration of figure by contrary refractions. But this is very ill founded. Huyghens has acquired sufficient reputation by his theory of aberrations. The scope of his writing in the passage alluded to, is to show that, by dividing any intended refraction into parts, and producing a certain convergence to or divergence from the axis of an optical instrument, by means of two or three lenses instead of one, we diminish the aberrations four or nine times. This conjecture about the eye was therefore in the natural train of his thoughts. But he did not think of destroying the aberration altogether by opposite refractions. Newton, in 1669, says that opticians need not trouble themselves about giving figures to their glasses other than spherical. If this figure were all the obstacle to the improvement of telescopes, he could show them a construction of an object-glass having spherical surfaces where the aberration is destroyed; and accordingly he gives the construction of one composed of glass and water, in which this is done completely by means of contrary refractions.

Fig. 7.



The general principle is this. When the radiant point R (fig. 7), or focus of incident rays, and its conjugate focus F of refracted central rays, are on opposite sides of the refracting surface or lens V, the conjugate focus f of marginal rays is nearer to R than F is. But when the focus of incident rays R′ lies on the same side with its conjugate focus F′ for central rays, R′f' is greater than R′ F′.

Fig. 8.

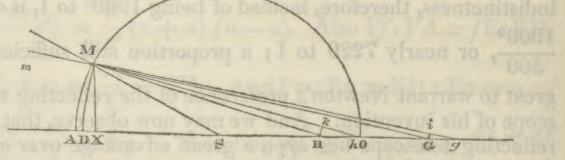


Now fig. 8 represents the contrivance for destroying the colour produced at F, the principal focus of the convex lens V, of crown glass, by means of the contrary refraction of the concave lens v of flint glass. The incident parallel rays are made to converge to F by the first lens. This convergence is diminished, but not entirely destroyed, by the concave lens v, and the focus is formed in F′. F and F′ therefore are conjugate foci of the concave lens. If F be the focus of V for central rays, the marginal rays will be collected at some point f nearer to the lens. If F be now considered as the focus of light incident on the centre of v, and F′ be the conjugate focus, the marginal ray p F′ would be refracted to some point f' lying beyond F′. Therefore the marginal ray pf may be refracted to F, if the aberration of the concave be properly adjusted to that of the convex.

This brings us to the most difficult part of our subject, the compounded aberrations of different surfaces. Our limits will not admit of our treating this in the same elementary and perspicuous manner that we employed for a single surface. We must try to do it in a compendious way, which will admit at once the different surfaces, and the different refractive powers of different substances. This must naturally render the process more complicated; but we hope to treat the subject in a way easily comprehended by any person moderately acquainted with common algebra.

Lemma 1. In the right-angled triangle MXS (fig. 9), of which one side MX is very small in comparison of either of the others, the excess of the hypothenuse MS above the side XS is very nearly equal to $\frac{MX^2}{2MS}$ or to $\frac{MX^2}{2XS}$. For if about the centre S, with the radius SM, we describe the semicircle AMO, we have $AX \cdot XO = MX^2$. Now $AX = MS - SX$, and XO is nearly equal to 2MS or 2XS; on the other hand, MS is nearly equal to $XS + \frac{MX^2}{2XS}$; and in like manner MG is nearly equal to $\frac{MX}{2XG} + XG$, and MH is nearly equal to $\frac{MX^2}{2XH} + XH$.

Fig. 9.



Prop. I. Let the ray mM, incident on the spherical surface AM, converge to G; that is, let G be the focus of incident rays. It is required to find the focus H of refracted rays.

Let m express the ratio of the sine of incidence and refraction; that is, let m be to 1 as the sine of incidence to the sine of refraction in the substance of the sphere.

Then $\mathrm{MG} : \mathrm{GS} = \sin.\ \mathrm{MSH} : \sin.\ \mathrm{SMG}$,
and $m : 1 = \sin.\ \mathrm{SMG} : \sin.\ \mathrm{SMH}$;
therefore $m \cdot \mathrm{MG} : \mathrm{GS} = \sin.\ \mathrm{MSH} : \sin.\ \mathrm{SMH}$.
Now S, MSH : S, SMH = MH : HS. Therefore, finally,
$m \cdot \mathrm{MG} : \mathrm{GS} = \mathrm{MH} : \mathrm{HS}$.

Now, let MS, the radius of the refracting surface, be called a. Let AG, the distance of the focus of incident rays from the surface, be called r. And let AH, the focal distance of refracted rays, be called x. Lastly, let the sine MX of the semi-aperture be called e. Observe, too, that a, r, x, are to be considered as positive quantities, when AS, AG, AH, lie from the surface in the direction in which the light is supposed to move. If therefore the refracting surface be concave, that is, having the centre on that side from which the light comes; or if the incident rays are divergent, or the refracted rays are divergent; then a, r, x, are negative quantities.

It is plain that $\mathrm{HS} = x - a$; $\mathrm{GS} = r - a$; also $\mathrm{AX} = \frac{e^2}{2a}$ nearly. $\mathrm{HX} = x - \frac{e^2}{2a}$. $\mathrm{GX} = r - \frac{e^2}{2a}$. Now add to HX and to GH their differences from MH and MG, which (by the Lemma) are $\frac{e^2}{2x}$ and $\frac{e^2}{2r}$. We get $\mathrm{MH} = x - \frac{e^2}{2a} + \frac{e^2}{2x}$, and $\mathrm{MG} = r - \frac{e^2}{2a} + \frac{e^2}{2r}$. In order to shorten our notation, make $k = \frac{1}{a} - \frac{1}{r}$. This will make $\mathrm{MG} = r - \frac{ke^2}{2}$.

Now substitute these values in the analogy $\mathrm{MH} : \mathrm{HS} = m \cdot \mathrm{MG} : \mathrm{GS}$; it becomes $x - \frac{e^2}{2a} + \frac{e^2}{2x} : x - a = mr - \frac{mke^2}{2} : r - a$ (or ark), because $k = \frac{r-a}{ar}$, and $ark = r - a$. Now multiply the extreme and mean terms of this analogy. It is evident that it must give us an equation which will give us a value of x or AH, the quantity sought.

But this equation is quadratic. We may avoid the solution by an approximation which is sufficiently accurate, by substituting for x in the fraction $\frac{e^2}{2x}$ (which is very small in all cases of optical instruments) an approximate value very easily obtained, and very near the truth. This is the focal distance of an infinitely slender pencil of rays converging to G. This we know by the common optical theorem to be $\frac{amr}{(m-1)r \pm a}$. Let this be called φ; if we substitute k in place of $\frac{1}{a} - \frac{1}{r}$, this value of φ becomes $= \frac{am}{m - ak}$. This gives us, by the by, an easily-remembered expression (and beautifully simple) of the refracted focus of an infinitely slender pencil, corresponding to any distance r of the radiant point. For since $\varphi = \frac{am}{m - ak}$; $\frac{1}{\varphi}$ must be $= \frac{m - ak}{am} = \frac{m}{am} - \frac{ak}{am} = \frac{1}{a} - \frac{k}{m}$. We may even express it more simply, by expanding k, and it becomes $\frac{1}{\varphi} = \frac{1}{a} - \frac{1}{ma} - \frac{1}{mr}$.

Now put this value of $\frac{1}{\varphi}$ in place of $\frac{1}{x}$ in the analogy employed above. The first term of the analogy becomes $x - \frac{e^2}{2a} + \frac{e^2}{2a} - \frac{ke^2}{2m}$, or $x - \frac{ke^2}{2m}$. The analogy now becomes $x - \frac{ke^2}{2m} : x - a = mr - \frac{mke^2}{2} : ark$. Hence we obtain the linear equation $mrx - \frac{mke^2x}{2} - mra + \frac{mkae^2}{2} = arkx - \frac{ark^2e^2}{2m}$; from which we finally deduce

$$x = \frac{mra - \frac{1}{2}make^2 - \frac{ark^2e^2}{2m}}{mr - ark - \frac{1}{2}mke}.$$

We may simplify this greatly by attending to the elementary theorem in fluxions, that the fraction $\frac{x + dx}{y + dy}$ differs from the fraction $\frac{x}{y}$ by the quantity $\frac{ydx + xdy}{y^2}$; this being the fluxion of $\frac{x}{y}$. Therefore $\frac{x + dx}{y + dy} = \frac{x}{y} + \frac{ydx + xdy}{y^2}$. Now the preceding formula is nearly in this situation. It may be written thus:

$\frac{mra - \left(\frac{1}{2}make^2 + \frac{ark^2e^2}{2m}\right)}{mr - ark - mke^2}$. Here the last terms of the numerator and denominator are very small in comparison with the first, and may be considered as the dx and dy, while mra is the x, and $mr - ark$ is the y. Treating it in this way, it may be stated thus:

$$x = \frac{ma}{m - ak} + \frac{(mra)\,mk - (mr - ark)\left(mka + \frac{ark^2}{m}\right)}{r^2(m - ak)^2} \cdot \tfrac{1}{2}e^2.$$

The first term $\frac{ma}{m - ak}$ is evidently $= \varphi$, the focal distance of an infinitely slender pencil. Therefore the aberration is expressed by the second term, which we must endeavour to simplify.

Now the numerator of the small fraction, by multiplication, may be expressed thus:

$$m^2a^2\left(\frac{rk^2}{m} - \frac{r^2k^2}{m^2a} + \frac{r^3k^3}{m^3}\right)\tfrac{1}{2}e^2.$$

The denominator was $r^2(m - ak)^2$, and the fraetion now becomes $\frac{m^2a^2}{(m - ak)^2}\left(\frac{k^2}{mr} - \frac{k^2}{m^2a} + \frac{k^3}{m^3}\right)\frac{1}{2}e^2$, which is evidently $= \varphi^2\left(\frac{k^2}{mr} - \frac{k^2}{m^2a} + \frac{k^3}{m^3}\right)\frac{e^2}{2}$. Now recollect that $k = \frac{1}{a} - \frac{1}{r}$. Therefore $\frac{k^3}{m^2} = \frac{k^2}{m^2}\left(\frac{1}{a} - \frac{1}{r}\right) = \frac{k^2}{m^2a} - \frac{k^2}{m^2r}$. Therefore, instead of $-\frac{k^2}{m^2a}$, write $\frac{-k^3}{m^2} - \frac{k^2}{m^2r}$, and we get the fraction $\varphi^2\left(\frac{k^3}{m^3} - \frac{k^3}{m^2} - \frac{k^2}{m^2r} + \frac{k^2}{mr}\right)\frac{e^2}{2} = \varphi^2\left(\frac{k^3}{m^3} - \frac{mk^3}{m^3} - \frac{mk^2}{m^3r} + \frac{m^2k^2}{m^3r}\right)\frac{e^2}{2}$, which is equal to $\varphi^2\frac{1 - m}{m^3}\left(k^3 - \frac{mk^2}{r}\right)\frac{e^2}{2}$, and finally to $-\varphi^2\frac{m - 1}{m^3}\left(k^3 - \frac{mk^2}{r}\right)\frac{e^2}{2}$.

Therefore the focal distance of refracted rays is

$$x = \varphi - \varphi^2\frac{m - 1}{m^3}\left(k^3 - \frac{mk^2}{r}\right)\frac{e^2}{2}.$$

This consists of two parts. The first, φ, is the focal distance of an infinitely slender pencil of central rays, and the other, $-\varphi^2 \frac{m-1}{m^3}\left(k^3 - \frac{mk^2}{r}\right)\frac{e^2}{2}$, is the aberration arising from the spherical figure of the refracting surface.

Thus our formula has at last assumed a very simple form, and is vastly preferable to Dr Smith's for practice.

This aberration is evidently proportional to the square of the semi-aperture, and to the square of the distance φ; but in order to obtain this simplicity, several quantities were neglected. The assumption of the equality of AX to $\frac{e^2}{2a}$ is the first source of error. A much more accurate value of it would have been $\frac{2ae^2}{4a^2 + e^2}$, for it is really $= \frac{e^2}{2a - \text{AX}}$. If for AX we substitute its approximated value $\frac{e^2}{2a}$, we should have $\text{AX} = \frac{e^2}{2a - \frac{e^2}{2a}} = \frac{2ae^2}{4a^2 - {}^2}$. To have used this value would not much have complicated the calculus; but it did not occur to us till we had finished the investigation, and it would have required the whole to be changed. The operation in page 149, col. 2, par. 1, is another source of error. But these errors are very inconsiderable when the aperture is moderate. They increase for the most part with an increase of aperture, but not in the proportion of any regular function of it; so that we cannot improve the formula by any manageable process, and must be contented with it. The errors are precisely the same with those of Dr Smith's theorem, and indeed with those of any that we have seen, which are not vastly more complicated.

As this is to be frequently combined with subsequent operations, we shorten the expression by putting θ for $\frac{m-1}{m^3}\left(k^3 - \frac{mk^2}{r}\right)\frac{e^2}{2}$. Then $\varphi^2\theta$ will express the aberration of the first refraction from the focal distance of an infinitely slender pencil; and now the focal distance of refracted rays is $f = \varphi - \varphi^2\theta$.

If the incident rays are parallel, r becomes infinite, and $\theta = \frac{m-1}{m^3} k^3 \frac{e^2}{2}$. But in this case k becomes $= \frac{1}{a}$, and $\frac{1}{\varphi} = \frac{m-1}{ma}$, and $\varphi = \frac{ma}{m-1}$, and $\varphi^2\theta$ becomes $\frac{m^2 a^2}{(m-1)^2} \times \frac{m-1}{m^3} \times \frac{1}{a^3} \times \frac{e^2}{2} = \frac{e^2}{(2m-1)\,ma}$. This is the aberration of extreme parallel rays.

We must now add the refraction of another surface.

Lemma 2. If the focal distance AG be changed by a small quantity Gg, the focal distance AH will also be changed by a small quantity Hh, and we shall have

$$m \cdot \text{AG}^2 : \text{AH}^2 = \text{G}g : \text{H}h.$$

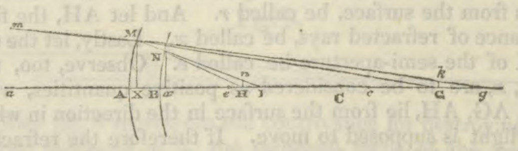
Draw Mg, Mh, and the perpendiculars Gi, Hk. Then, because the sines of the angles of incidence are in a constant ratio to the sines of the angles of refraction, and the increments of these small angles are proportional to the increments of the sines, these increments of the angles are in the same constant ratio. Therefore we have the angle GMg to HMh as m to 1.

Now Gg : Gi = AG : AM,
and Gi : hk = $m \cdot$ AG : HA,
and hk : Hh = MA : AH;
therefore Gg : Hh = $m \cdot$ AG² : AH².

The easiest and most perspicuous method for obtaining the aberration of rays twice refracted, will be to consider the first refraction as not having any aberration, and determine the aberration of the second refraction. Then conceive the focus of the first refraction as shifted by the aberration. This will produce a change in the focal distance of the second refraction, which may be determined by this Lemma.

Prop. II. Let AM, BN (fig. 10) be two spherical surfaces, including a refracting substance, and having their centres C and c in the line AG. Let the ray aA pass through the centres, which it will do without refraction. Let another ray mM, tending to G, be refracted by the first surface into MH, cutting the second surface in N, where it is farther refracted into NI. It is required to determine the focal distance BI.

Fig. 10.



It is plain that the sine of incidence on the second surface is to the sine of refraction into the surrounding air as 1 to m. Also BI may be determined in relation to BH, by means of BH, Nx, Be, and $\frac{1}{m}$, in the same way that AH was determined in relation to AG, by means of AG, MX, AC, and m.

Let the radius of the second surface be b, and let e still express the semi-aperture (because it hardly differs from Nx). Also let α be the thickness of the lens. Then observe, that the focal distance of the rays refracted by the first surface (neglecting the thickness of the lens and the aberration of the first surface), is the distance of the radiant point for the second refraction, or is the focal distance of rays incident on the second surface. In place of r therefore we must take φ; and as we made $k = \frac{1}{a} - \frac{1}{r}$, in order to abbreviate the calculus, let us now make $l = \frac{1}{b} - \frac{1}{\varphi}$; and make $\frac{1}{f} = \frac{1}{b} - ml$, as we made $\frac{1}{\varphi} = \frac{1}{a} - \frac{k}{m}$. Lastly, in place of $\theta = \frac{m-1}{m^3}\left(k^3 - \frac{mk^2}{r}\right)\frac{e^2}{2}$, make $\theta' = \left(\frac{1}{m} - 1\right)m^3 \left(l^3 - \frac{l^2}{m\varphi}\right)\frac{e^2}{2} = -\frac{m-1}{m}\left(m^3 l^3 - \frac{m^2 l^2}{\varphi}\right)\frac{e^2}{2}$.

Thus we have got an expression similar to the other; and the focal distance BI, after two refractions, becomes $\text{BI} = f - f^2\theta'$.

But this is on the supposition that BH is equal to φ, whereas it is really $\varphi - \varphi^2\theta - \alpha$. This must occasion a change in the value just now obtained of BI. The source of the change is twofold. 1st, Because in the value $\frac{1}{b} - \frac{1}{\varphi}$, we must put $\frac{1}{b} - \frac{1}{\varphi - \varphi^2\theta - \alpha}$, and because we must do the same in the fraction $\frac{m^2 l^2}{\varphi}$. In the second place, when the value of BH is diminished by the quantity $\varphi^2\theta + \alpha$, BI will suffer a change in the proportion determined by the second Lemma. The first difference may safely be neglected, because the value of θ' is very small, by reason of the co-efficient $\frac{e^2}{2}$ being very small, and also because the variation bears a very small ratio to the quantity itself, when the true value of φ differs but little from that of the quantity for which it is employed. The chief change in BI is that which is determined by the Lemma. Therefore take from BI the variation of BH, multiplied by $\frac{m\mathrm{BI}^2}{\mathrm{BH}^2}$, which is very nearly $= \frac{mf^2}{\varphi^2}$. The product of this multiplication is $mf^2\,\theta + \frac{mf^2\,\alpha}{\varphi^2}$. This being taken from f, leaves us for the value of BI,

$$f - \frac{f^2\,m\alpha}{\varphi^2} - f^2\,(m\theta + \theta').$$

In this value f is the focal distance of an infinitely slender pencil of rays twice refracted by a lens having no thickness, $\alpha\,\frac{mf^2}{\varphi}$ is the shortening occasioned by the thickness, and $f^2\,(m\,\theta + \theta')$ is the effect of the two aberrations arising from the aperture.

It will be convenient, for several collateral purposes, to exterminate from these formulæ the quantities k, l, and φ. For this purpose, make $\frac{1}{n} = \frac{1}{a} - \frac{1}{b}$. We have already $k = \frac{1}{a} - \frac{1}{r}$; and $\frac{1}{\varphi} = \frac{1}{a} - \frac{1}{ma} + \frac{1}{mr}$; and $l = \frac{1}{b} - \frac{1}{\varphi} = \frac{1}{b} - \frac{1}{a} + \frac{1}{ma} - \frac{1}{mr}$. Now for $\frac{1}{b} - \frac{1}{a}$ write $-\frac{1}{n}$, and we get $l = \frac{1}{ma} - \frac{1}{mr} - \frac{1}{n}$. Therefore $\frac{1}{f} = \frac{1}{b} - ml$ (by construction, page 150, Prop. II.) becomes $= \frac{1}{b} - \frac{1}{a} + \frac{1}{r} + \frac{m}{n} = \frac{m}{n} + \frac{1}{r} - \frac{1}{n} = \frac{m-1}{n} + \frac{1}{r}$.

This last value of $\frac{1}{f}$ (the reciprocal of the focus of a slender pencil twice refracted), viz. $\frac{m-1}{n} + \frac{1}{r}$, is the simplest that can be imagined, and makes n as a substitute for $\frac{1}{a} - \frac{1}{b}$; a most useful symbol, as we shall frequently find in the sequel. It also gives a very simple expression of the focal distance of parallel rays, which we may call the principal focal distance of the lens, and distinguish it in future by the symbol p; for the expression $\frac{1}{f} = \frac{m-1}{n} + \frac{1}{r}$ becomes $\frac{1}{p} = \frac{m-1}{n}$ when the incident light is parallel. And this gives us another very simple and useful measure of f; for $\frac{1}{f}$ becomes $= \frac{1}{p} + \frac{1}{r}$. These equations, $\frac{1}{f} = \frac{m-1}{n} + \frac{1}{r}$, $\frac{1}{p} = \frac{m-1}{n}$, and $\frac{1}{f} = \frac{1}{p} + \frac{1}{r}$, deserve therefore to be made very familiar to the mind.

We may also take notice of another property of n. It is half the radius of an isosceles lens, which is equivalent to the lens whose radii are a and b; for suppose the lens to be isosceles, that is, $a = b$; then $n = \frac{1}{a} - \frac{1}{a}$. Now the second a is negative if the first be positive, or positive if the first be negative. Therefore $\frac{1}{a} - \frac{1}{b} = \frac{a+b}{a^2} = \frac{a+a}{a^2} = \frac{2}{a}$, and $\frac{1}{n} = \frac{2}{a}$, and $n = \frac{a}{2}$. Now the focal distance of this lens is $\frac{m-1}{n}$, and so is that of the other, and they are equivalent.

But, to proceed with our investigation, recollect that we had $\theta = \frac{m-1}{m^3}\left(k^3 - \frac{mk^2}{r}\right)\frac{e^2}{2}$. Therefore $m\,\theta = \frac{m-1}{m}\left(\frac{k^3}{m} - \frac{k^2}{r}\right)\frac{e^2}{2}$. And θ' was $= \frac{m-1}{m}\left(-m^3\,l^3 + \frac{m^2l^2}{\varphi}\right)\frac{e^2}{2}$. Therefore $f^2(m\theta + \theta')$, the aberration (neglecting the thickness of the lens), is $f^2\,\frac{m-1}{m}\left(\frac{k^3}{m} - \frac{k^2}{r} - m^3\,l^3 + \frac{m^2l^2}{\varphi}\right)\frac{e^2}{2}$.

If we now write for k, l, and φ, their values as determined above, performing all the necessary multiplications, and arrange the terms in such a manner as to collect in one sum the co-efficients of a, n, and r, we shall find four terms for the value of $m\theta$, and ten for the value of θ'. The four are destroyed by as many with contrary signs in the value of θ', and there remain six terms to express the value of $m\theta + \theta'$, which we shall express by one symbol q; and the equation stands thus:

$$q = \frac{m-1}{m}\left(\frac{m^3}{n^3} - \frac{2m^2+m}{an^2} + \frac{m+2}{a^2n} + \frac{3m^2+m}{rn^2} - \frac{4m+4}{arn} + \frac{3m+2}{r^2n}\right)\frac{e^2}{2}.$$

The focal distance therefore of rays twice refracted, reckoned from the last surface, or BI, corrected for aberration, and for the thickness of the lens, is $f - f^2\,\frac{m\alpha}{\varphi^2} - f^2\,q$, consisting of three parts, viz. f, the focal distance of central rays; $f^2\,\frac{m\alpha}{\varphi^2}$, the correction for the thickness of the lens; and $f^2\,q$, the aberration.

The preceding formula appears very complex, but is of very easy management, requiring only the preparation of the simple numbers which form the numerators of the fractions included in the parenthesis. When the incident rays are parallel, the terms vanish which have r in the denominator, so that only the first three terms are used.

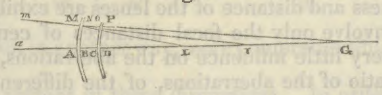
We might here point out the cases which reduce the aberration expressed in the formula last referred to, to nothing; but as they can scarcely occur in the object-glass of a telescope, we omit it for the present, and proceed to the combination of two or more lenses.

Lemma 3. If AG be changed by a small quantity Gg; BI suffers a change Ii, and Gg : Ii = AG² : BI². For it is well known that the small angles GMg and INi are equal; and therefore their subtenses Gk, In are proportional to MG, NI, or to AG, AI nearly, when the aperture is moderate. Therefore we have (nearly)

Gk : In : AG : BI,
In : Ii = AM : BI,
Gg : Gk = AG : AM,
Therefore Gg : Ii = AG² : BI².

Prop. III. To determine the focal distance of rays refracted by two lenses placed near to each other on a common axis.

Fig. 11.



Let AM, BN (fig. 11) be the surfaces of the first lens, and CO, DP be the surfaces of the second, and let β be the thickness of the second lens, and δ the interval between them. Let the radius of the anterior surface of the second lens be a', and the radius of its posterior surface be b'. Let m' be to 1 as the sine of incidence to the sine of refraction in the substance of the second lens. Lastly, let p' be the principal focal distance of the second lens. Let the extreme or marginal ray meet the axis in L after passing through both lenses, so that DL is the ultimate focal distance, reckoned from the last surface.

It is plain that DL may be determined by means of a', b', m', p', and CI in the same manner that BI was determined by means of a, b, m, p, and AG.

The value of BI is $f - m\alpha\frac{f^2}{\varphi^2} - f^2 q$. Take from this the interval δ, and we have $CI = f - m\alpha\frac{f^2}{\varphi^2} - \delta - f^2 q$. Let the small part $- m\alpha\frac{f^2}{\varphi^2} - \delta - f^2 q$ be neglected for the present, and let CI be supposed $= f$: As we formed φ, f, and q, by means of a, b, m, n, and r, let us now form φ', f', and q', for the second lens, by means of a', b', m', n' $\left(= \frac{1}{a'} - \frac{1}{b'}\right)$, and r'; then φ' will be the focal distance of a slender pencil refracted by the first surface, f' will be the focal distance of this pencil after two refractions, and q' will be the co-efficient of the aberration, neglecting the thickness and interval of the lenses.

Proceeding in this way, DL will be $= f' - m\beta\frac{f'^2}{\varphi'^2} - f'^2 q'$. But because CI is really less than f, by the quantity $m\alpha\frac{f^2}{\varphi'^2} + \delta + f^2 q'$, we must (by Lemma 3) subtract the product of this quantity, multiplied by $\frac{DL}{BI^2}$ (which is nearly $\frac{f'^2}{f^2}$), from $f' - m\beta\frac{f'^2}{\varphi'^2} f'^2 q'$.

By this process we shall have

$$DL = f' - f'^2\left(\frac{m\alpha}{\varphi^2} + \frac{\delta}{f^2} + \frac{m'\beta}{\varphi'^2}\right) - f'^2(q + q').$$

The first term f' of this value of DI is the focal distance of a slender pencil of central rays refracted by both lenses, neglecting their thickness and distance; the second term, $-f'^2\left(\frac{m\alpha}{\varphi^2} + \frac{\delta}{f^2} + \frac{m'\beta}{\varphi'^2}\right)$, is the correction necessary for these circumstances; and the third term, $-f'^2(q + q')$, is the correction for the aperture $2e$. And it is evident that q' is a formula precisely similar to q, containing the same number of terms, and differing only by the m', a', n', and r', employed in place of m, a, n, and r.

It is also evident, that if there be a third lens, we shall obtain its focal distance by a process precisely similar to that by which we obtained DL; and so on for any number of lenses.

Thus have we obtained formulæ by which the foci of rays are determined in the most general terms, and in such a manner as shall point out the connection of the curvatures, thicknesses, and distances of the lenses, with their spherical aberrations, and with the final aberration of the compound lens, and give the aberrations in separate symbols, so that we can treat them by themselves, and subject them to any conditions which may enable us to correct one of them by another.

We also see in general, that the corrections for the thickness and distance of the lenses are exhibited in terms which involve only the focal distances of central rays, and have very little influence on the aberrations, and still less on the ratio of the aberrations, of the different lenses. This is a most convenient circumstance; for we may neglect them while we are determining q and q', and in determining the ratio of the focal distances of the several lenses, on which the correction of the chromatic aberration chiefly depends. Therefore, in the construction of a compound lens for uniting the different colours, we may neglect this correction for the thickness and distance till the end of the process. When we apply it, we shall find that it chiefly affects the final focal distance, making it somewhat longer, but has hardly any influence either on the chromatic or spherical aberration. We do not hesitate to say, that the final formulæ here given are abundantly accurate, while they are vastly more manageable than those employed by Euler or D'Alembert. We have calculated trigonometrically the progress of the rays through one of the glasses, which will be given as an example, giving it a very extravagant aperture, that the errors of the formulæ might be very remarkable. We found the real aberration exceed the aberration assigned by the formula by no more than $\frac{1}{50}$th part, a difference which is quite insignificant. The process here given derives its simplicity from the frequent occurrence of harmonic proportions in all optical theorems. This enabled M. Clairaut to employ the reciprocals of the radii and distances with so much simplicity and generality.

We consider it as another advantage of M. Clairaut's method, that it gives, by the way, formulæ for the more ordinary questions in optics, which are of wonderful simplicity, and most easily remembered. The chief problems in the elementary construction of optical instruments relate to the focal distances of central rays. This determines the focal distances and arrangement of the glasses. All the rest may be called the refinement of optics; teaching us how to avoid or correct the indistinctness, the colours, and the distortions, which are produced in the images formed by these simple constructions.

Let m be to 1 as the sine of incidence to the sine of refraction; let a and b be the radii of the anterior and posterior surfaces of a lens; let r be the distance of the radiant point, or the focus of incident central rays, and f the distance of the conjugate focus; and let p be the principal focal distance of the lens, or the focal distance of parallel rays. Make $\frac{1}{n}$ equal to $\frac{1}{a} - \frac{1}{b}$; let the same letters a', b', r', &c. express the same things for a second lens; and a'', b'', r'', &c. express them for a third; and so on. Then we have $\frac{1}{f} = \frac{m-1}{n} + \frac{1}{r}$; $\frac{1}{f'} = \frac{m'-1}{n'} + \frac{1}{r'}$; $\frac{1}{f''} = \frac{m''-1}{n''} + \frac{1}{r''}$, &c.

Therefore, when the incident light is parallel, and r infinite, we have $\frac{1}{p} = \frac{m-1}{n}$; $\frac{1}{p'} = \frac{m'-1}{n'}$; $\frac{1}{p''} = \frac{m''-1}{n''}$, &c.

And when several lenses are contiguous, so that their intervals may be neglected, and therefore $\frac{1}{f}$, belonging to the first lens, becomes $\frac{1}{r'}$, belonging to the second, we have

1. $\frac{1}{r'} = \frac{1}{f} = \frac{m-1}{n} + \frac{1}{r} = \frac{1}{p} + \frac{1}{r}$;

2. $\frac{1}{r''} = \frac{1}{f'} = \frac{m'-1}{n'} + \frac{m-1}{n} + \frac{1}{r} = \frac{1}{p'} + \frac{1}{p} + \frac{1}{r}$;

3. $\frac{1}{f''} = \frac{m''-1}{n''} + \frac{m'-1}{n} + \frac{m-1}{n} + \frac{1}{r} = \frac{1}{p''} + \frac{1}{p'} + \frac{1}{p} + \frac{1}{r}$.

Nothing can be more easily remembered than these formulæ, how numerous soever the glasses may be.

Having thus obtained the necessary analysis and formula, it now remains to apply them to the construction of achromatic lenses, in which it fortunately happens that the employment of several surfaces, in order to produce the union of the differently refrangible rays, enables us at the same time to employ them for correcting each other's spherical aberration.

A white or compounded ray is separated by refraction into its component coloured rays, and they are diffused over a small angular space. Thus it appears, that the glass used by Sir Isaac Newton in his experiments diffused a white ray, which was incident on its posterior surface in an angle of 30°, in such a manner that the extreme red ray emerged into air, making an angle of 50° 21⅓' with the perpendicular; the extreme violet ray emerged in an angle of 51° 15⅗'; and the ray which was in the confines of green and blue, emerged in an angle of 50° 48⅓'. If the sine of the angle 30° of incidence be called 0·5, which it really is, the sine of the emergence of the red ray will be 0·77, that of the violet ray will be 0·78, and that of the intermediate ray will be 0·77½, an exact mean between the two extremes. This ray may therefore be called the mean refrangible ray, and the ratio of 77½ to 50, or of 1·55 to 1, will very properly express the mean refraction of this glass; and we have for this glass $m = 1{\cdot}55$. The sine of refraction, being measured on a scale of which the sine of incidence occupies 100 parts, will be 154 for the red ray, 155 for the mean ray, and 156 for the violet ray. This number, or its ratio to unity, is commonly taken to represent the refractive power of the glass. There is some impropriety in this, unless we consider ratios as measured by their logarithms; for if m be 1, the substance does not refract at all. The refractive power can be properly measured only by the refraction which it produces; that is, by the change which it makes in the direction of the light, or the angle contained between the incident and refracted rays. If two substances produce such deviations always in one proportion, we should then say that their refractive powers are in that proportion. This is not true in any substances; but the sines of the angles contained between the refracted ray and the perpendicular, are always in one proportion when the angle of incidence in both substances is the same. This being a cognisable function of the real refraction, has therefore been assumed as the only convenient measure of the refractive powers. Although it is not strictly just, it answers extremely well in the most usual cases in optical instruments. The refractions are moderate, and the sines are very nearly as the angles contained between the rays and the perpendicular; and the real angles of refraction, or deflections of the rays, are almost exactly proportional to $m - 1$. The most natural and obvious measure of the refractive powers would therefore be $m - 1$. But this would embarrass some very frequent calculations; and we therefore find it best, on the whole, to take m itself for the measure of the refractive power.

The separation of the red, violet, and intervening rays, has been called *dispersion;* and although this arises merely from a difference of the refractive power in respect of the different rays, it is convenient to distinguish this particular modification of the refractive power by a name, and we call it the *dispersive power* of the refracting substance.

It is susceptible of degrees; for a piece of flint-glass will refract the light, so that when the sine of refraction of the red ray is 77, the sine of the refraction of the violet ray is nearly 78½; or if the sine of refraction of the red ray, measured on a particular scale, is 1·54, the sine of refraction of the violet ray is 1·57. The dispersion of this substance, being measured by the difference of the extreme sines of refraction, is greater than the dispersion of the other glass, in the proportion of three to two.

But this alone is not a sufficient measure of the absolute dispersive power of a substance. Although the ratio of 1·54 to 1·56 remains constant, whatever the real magnitude of the refractions of common glass may be, and though we therefore say that its dispersive power is constant, we know that by increasing the incidence and the refraction, the absolute dispersion is also increased. Another substance shows the same properties, and in a particular case may produce the same dispersion; yet it has not for this sole reason the same dispersive power. If indeed the incidence and the refraction of the mean ray be also the same, the dispersive power cannot be said to differ; but if the incidence and the refraction of the mean ray be less, the dispersive power must be considered as greater, though the actual dispersion be the same; because if we increase the incidence till it becomes equal to that in the common glass, the dispersion will now be increased. The proper way of conceiving the dispersion therefore is, to consider it as a portion of the whole refraction; and if we find a substance making the same dispersion with half the general refraction, we must say that the dispersive quality is double, because by making the refraction equal, the dispersion will really be double.

If therefore we take dm as a symbol of the separation of the extreme rays from the middle ray, $\frac{dm}{m-1}$ is the natural measure of the dispersive power.

It is not unusual for optical writers to take the whole separation of the red and violet rays for the measure of the dispersive power, and to compare this with the refracting power with respect to one of the extreme rays. But it is surely better to consider the mean refraction as the measure of the refracting power; and the deviation of either of the extremes from this mean is a proper enough measure of the dispersion, being always half of it. It is attended with this convenience, that being introduced into our computations as a quantity infinitely small, and treated as such for the ease of computation, while it is really a quantity of sensible magnitude, the errors arising from this supposition are diminished greatly by taking one half of the deviation and comparing it with the mean refraction. This method has, however, this inconvenience, that it does not exhibit at once the refractive power in all substances respecting any particular colour of light; for it is not the ray of any particular colour that suffers the mean refraction. In common glass it is the ray which is in the confines of the yellow and blue, in flint-glass it is nearly the middle blue ray, and in other substances it is a different ray. These circumstances appear plainly in the different proportions of the colours of the prismatic spectrum exhibited by different substances. This will be considered afterwards, being a great bar to the perfection of achromatic instruments.

The way in which an achromatic lens is constructed is, to make use of a contrary refraction of a second lens to destroy the dispersion or spherical aberration of the first.

The first purpose will be answered if $\frac{dm}{n}$ be equal to $-\frac{dm'}{n'}$. For, in order that the different coloured rays may be collected into one point by two lenses, it is only necessary that $\frac{1}{f'}$, the reciprocal of the focal distance of rays refracted by both, may be the same for the extreme and mean rays, that is, that $\frac{m+dm-1}{n} + \frac{m'+dm'-1}{n'} + \frac{1}{r}$ be of the same value with $\frac{m-1}{n} + \frac{m'-1}{n'} + \frac{1}{r}$, which must happen if $\frac{dm}{n} + \frac{dm'}{n'}$ be $= 0$, or $\frac{dm}{n} = -\frac{dm'}{n}$. This may be seen in another way, more comprehensible by such as are not versant in these discussions. In order that the extreme colours which are separated by the first lens may be rendered parallel by the second, we have shown already that n and n' are proportional to the radii of the equivalent isosceles lenses, being the halves of these radii. In these small refractions they are therefore inversely proportional to the angles formed by the surfaces at the edges of the lenses: n' may therefore be taken for the angle of the first lens, and n for that of the second. Now the small refraction by a prism whose angle (also small) is n', is $(m-1)\,n$. The dispersive power being now substituted for the refractive power, we have for this refraction of the prism $dm \times n'$. This must be destroyed by the opposite refraction of the other prism $dm' \times n$. Therefore $dm \times n' = dm' \times n$, or $\frac{dm}{n} = -\frac{dm'}{n'}$. In like manner, this effect will be produced by three lenses if $\frac{dm}{n} + \frac{dm'}{n'} + \frac{dm''}{n''}$ be $= 0$, &c.

Lastly, the errors arising from the spherical figure, which we expressed by $-\mathrm{R}^2\,(q+q')$, will be corrected if $q+q'$ be $= 0$. We are therefore to discover the adjustments of the quantities employed in the preceding formulæ, which will insure these conditions. It will render the process more perspicuous if we collect into one view the significations of our various symbols, and the principal equations which we are to employ.

1. The ratios to unity of the sines of mean incidence in the different media are.............. m, m', m''.

2. The ratio of the differences of the sines of the extremes.. $\frac{dm}{dm'} = u$.

3. The ratio $\frac{m-1}{m'-1}$ .... $= c$.

4. The radii of the surfaces .... $a, b\,;\ a', b'\,;\ a'', b''$.

5. The principal focal distances, or the focal distances of parallel central rays .... p, p', p''.

6. The focal distance of the compound lens............ P.

7. The distance of the radiant point, or of the focus of incident rays on each lens .... r, r', r''.

8. The focal distance of the rays refracted by each lens .... f, f', f''.

9. The focal distance of rays refracted by the compound lens .... F.

10. The half breadth of the lens .... e.

Also the following subsidiary values:

1. $\frac{1}{n} = \frac{1}{a} - \frac{1}{b}$; $\frac{1}{n'} = \frac{1}{a'} - \frac{1}{b'}$; $\frac{1}{n''} = \frac{1}{a''} - \frac{1}{b''}$.

2. $q = \frac{m-1}{m}\left(\frac{m^3}{n^3} - \frac{2\,m^2+m}{an^2} + \frac{m+2}{a^2n} + \frac{3\,m^2+m}{rn^2} - \frac{4\,(m+1)}{arn} + \frac{3\,m+2}{r^2n}\right)\frac{e^2}{2}$. And q' and q'' must be formed in the same manner from m', a', n', r'; and from m'', a'', n'', r'', as q is formed from m, a, n, r.

3. Also because in the case of an object-glass, r is infinitely great, the last term $\frac{1}{r}$ in all the values of $\frac{1}{f}, \frac{1}{f'}, \frac{1}{f''}, \frac{1}{r'}, \frac{1}{r''}$, will vanish, and we shall also have $\mathrm{F} = \mathrm{P}$.

Therefore in a double object-glass $\frac{1}{\mathrm{P}} = \frac{m'-1}{n'} + \frac{m-1}{n} = \frac{1}{p} + \frac{1}{p'}$.

And in a triple object-glass $\frac{1}{\mathrm{P}} = \frac{m''-1}{n''} + \frac{m'-1}{n'} + \frac{m-1}{n} = \frac{1}{p''} + \frac{1}{p'} + \frac{1}{p}$.

Also, in a double object-glass, the correction of spherical aberration requires $q + q' = v$.

And a triple object-glass requires $q + q' + q'' = v$. For the whole error is multiplied by F^2, and by $\frac{1}{2}\,e^2$; and therefore the equation which corrects this error may be divided by $\mathrm{F}^2\,\frac{1}{2}\,e^2$.

The equation in the 14th line from the bottom of the column, giving the value of q, q', q'', may be much simplified as follows: In the first place, they may be divided by m, m', or m'', by applying them properly to the terms within the parenthesis, and expunging them from the denominator of the general factors $\frac{m-1}{m}$, $\frac{m'-1}{m'}$, $\frac{m''-1}{m''}$. This does not alter the values of q, q', and q''. In the second place, the whole equations may afterwards be divided by $m'-1$. This will give the values of $\frac{q}{m'-1}$, $\frac{q'}{m'-1}$, and $\frac{q''}{m'-1}$, which will still be equal to nothing if $q + q' + q''$ be equal to nothing.

This division reduces the general factor $\frac{m'-1}{m'}$ of q' to $\frac{1}{m'}$ And in the equation for q we obtain, in place of the general factor $\frac{m-1}{m}$, the factor $\frac{m-1}{m'-1}$, or c. This will also be the factor of the value of q'' when the third lens is of the same substance with the first, as is generally the case. And, in the third place, since the rays incident on the first lens are parallel, all the terms vanish from the value of q in which $\frac{1}{r}$ is found, and there remain only the first three, viz. $\frac{m^3}{n^3} - \frac{2\,m^2+m}{an^2} + \frac{m+2}{a^2n}$.

Performing these operations, we have

$$\frac{q}{m'-1} = c\left(\frac{m^2}{n^3} - \frac{2m+1}{an^2} + \frac{m+2}{ma^2n}\right)\frac{e^2}{2},$$

$$\frac{q'}{m'-1} = \left(\frac{m'^2}{n^{3'}} - \frac{2m'+1}{a'n'^2} + \frac{m'+2}{m'a'^2n'} + \frac{3m'+1}{r'n'^2} - \frac{(4m'+1)}{m'a'r'n'} + \frac{3'm+2}{m'r'^2n'}\right)\frac{e^2}{2},$$

$$\frac{q''}{m'-1} = c\left(\frac{m^2}{n''^3} - \frac{2m+1}{a''n''^2} + \frac{m+2}{m''a''^2n''} + \frac{3m+1}{r''n''^2} + \frac{(4m+1)}{m''a''r''n''} + \frac{3m+2}{m''r''^2n''}\right)\frac{e^2}{2}.$$

Let us now apply this investigation to the construction of an object-glass; and we shall begin with a double lens.

Construction of a Double Achromatic Object-glass.

Here we have to determine four radii, a, b, a', and b'. Make $n = 1$. This greatly simplifies the calculus, by exterminating n from all the denominators. This gives for the equation $\frac{dm}{n} + \frac{dm'}{n'} = 0$, the equation $dm + \frac{dm'}{n'} = 0$, or $dm = -\frac{dm'}{n'}$ and $\frac{1}{n'} = -\frac{dm}{dm'} = -u$. Also we have r', the focal distance of the light incident on the second lens, the same with the principal focal distance p of the first lens (neglecting the interval, if any). Now $\frac{1}{p'} = \frac{m-1}{n}$, which in the present case is $= m - 1$. Also $\frac{1}{p}$ is $= -u\,(m'-1)$, and $\frac{1}{\mathrm{P}} = m - 1 - u\,(m'-1) = u'$.

Make these substitutions in the values of $\frac{q}{m-1}$ and $\frac{q'}{m'-1}$, and we obtain the following equation.

$$cm^2 - \frac{c(2m+1)}{a} + \frac{c(m+2)}{ma^2} - u^3m'^2 - \frac{u^2(2m'+1)}{a'}$$
$$- \frac{u(m'+2)}{m'a'^2} + u^2(3m'+1)(m-1) + \frac{4u(m'+1)(m-1)}{m'a'}$$
$$- \frac{u(3m'+2)(m-1)^2}{m'} = 0.$$

Arrange these terms in order, according as they are factors of $\frac{1}{a^2}, \frac{1}{a}, \frac{1}{a'^2}, \frac{1}{a'}$, or independent quantities. It puts on this form:

$$c\frac{(m+2)}{m} \cdot \frac{1}{a^2} - c(2m+1) \cdot \frac{1}{a} - \frac{u(m'+2)}{m'} \cdot \frac{1}{a'^2}$$
$$- \left\{ u^2(2m'+1) - \frac{4u(m'+1)(m-1)}{m'} \right\} \cdot \frac{1}{a'} + cm^2 + u^2$$
$$(3m+1)(m-1) - u^3m'^2 - \frac{u(3m'+2)(m-1)^2}{m'} = 0.$$

Let A be the co-efficient of $\frac{1}{a^2}$, B that of $\frac{1}{a}$, C that of $\frac{1}{a'^2}$, D that of $\frac{1}{a'}$, and E the sum of the independent quantity; that is, let A be $= \frac{c(m+2)}{m}$, B $= c(2m+1)$, C $= \frac{u(m'+2)}{m'}$, D $= u^2(2m'+2) - \frac{4u(m'+1)(m-1)}{m'}$, and E $= cm^2 + u^2(3m'+1)(m-1) - u^3m'^2 - \frac{u(3m'+2)(m-1)^2}{m'}$.

Our final equation becomes

$$\frac{A}{a^2} - \frac{B}{a} - \frac{C}{a'^2} - \frac{D}{a'} + E = 0.$$

The co-efficients of this equation, and the independent quantity, are all known, from our knowledge of m, m', dm, dm'; and we are to find the values of a and a', and from them, and $n = 1$, to find the values of b and b'.

But it is evidently an indeterminate equation, because there are two unknown quantities, so that there may be an infinity of solutions. It must be rendered determinate by means of some other conditions to which it may be subjected. These conditions must depend on some other circumstances, which may direct our choice.

One circumstance occurs to us which we think of very great consequence. In the passage of light from one substance to another, there is always a considerable portion reflected from the posterior surface of the first and from the anterior surface of the last; and this reflection is more copious in proportion to the refraction. This loss of light will therefore be diminished by making the internal surfaces of the lenses to coincide, that is, by making $b = a'$. This will be attended with another advantage. If we put between the glasses a substance of nearly the same refracting power, we shall not only completely prevent this loss of light, but we shall greatly diminish the errors which arise from an imperfect polish of the surfaces. We have tried this, and find the effect very surprising. The lens being polished immediately after the figure has been given it, and while it was almost impervious to light by reason of its roughness, which was still sensible to the naked eye, performed as well as when finished in the finest manner.

This condition, by taking away one refraction, obliges us to increase those which remain, and therefore increases the spherical aberrations. And since our formulæ do not fully remove those (by reason of the small quantities neglected in the process), it is uncertain whether this condition be the most eligible. We have, however, no direct argument to the contrary.

Let us see what determination this gives us.

In this case $\frac{1}{a'} = \frac{1}{b} = \frac{1}{a} - 1$. For because $\frac{1}{n} = \frac{1}{a} - \frac{1}{b}$ and $n = 1$, we have $1 + \frac{1}{b} = \frac{1}{a}$, and $\frac{1}{b} = \frac{1}{a} - 1$. Therefore $\frac{1}{a'^2} = \frac{1}{a^2} - \frac{2}{a} + 1$. Therefore, in our final equation, put $\frac{1}{a^2} - \frac{2}{a} + 1$ in place of $\frac{1}{a'^2}$, and $\frac{1}{a} - 1$ in place of $\frac{1}{a'}$, and it becomes $\frac{A-C}{a^2} - \frac{B+D-2C}{a} + E + D - C = 0$.

Thus have we arrived at a quadratic equation, where $\frac{1}{a}$ is the unknown quantity. It has the form $px^2 + qx + r = 0$, where $p = A - C$, $q = 2C - B - D$, $r = E + D - C$ and $x = \frac{1}{a}$.

Divide the equation by p, and we have $x^2 + \frac{q}{p}x + \frac{r}{p} = 0$. Make $s = \frac{q}{p}$ and $t = \frac{r}{p}$, and we have $x^2 + sx + t = 0$. This gives us finally $\frac{1}{a}$, or $x = -\frac{1}{2}s \pm \sqrt{\frac{1}{4}s^2 - t}$.

This value of $\frac{1}{a}$ is taken from a scale of which the unit is half the radius of the isosceles lens which is equivalent to the first lens, or has the same focal distance with it. We must then find (on the same scale) the value of b, viz. $\frac{1}{a} - 1$, which is also the value of a'. Having obtained a', we must find b' by means of the equation $\frac{1}{n'} = \frac{1}{a'} - \frac{1}{b'}$, and therefore $\frac{1}{b} = \frac{1}{a'} - \frac{1}{n'}$. But $\frac{1}{n'} = u$. Therefore $\frac{1}{b'} = \frac{1}{a'} + u = \frac{1}{a} + u - 1$.

Thus is our object-glass constructed; and we must determine its focal distance, or its reciprocal $\frac{1}{P}$. This is $= m - 1 - u(m' - 1)$.

All these radii and distances are measured on a scale of which n is the unit. But it is more convenient to measure every thing by the focal distance of the compound object-glass. This gives us the proportion which all the distances bear to it. Therefore, calling P unity, in order to obtain $\frac{1}{a}$ on this scale, we have only to state the analogy $m - 1 - u(m' - 1) : 1 = \frac{1}{a} : \frac{1}{A}$, and A is the radius of our first surface measured on a scale of which P is the unit.

If, in the formula which expresses the final equation for $\frac{1}{a}$, the value of t should be positive, and greater than $\frac{1}{4}s^2$, the equation has imaginary roots; and it is not possible, with the glasses employed and the conditions assumed, to correct both the chromatic and spherical aberrations.

If t is negative and equal to $\frac{1}{4}s^2$, the radical part of the value is $= 0$, and $\frac{1}{a} = -\frac{1}{2}s$. But if it be negative or positive, but less than $\frac{1}{4}s^2$, the equation has two real roots, which will give two constructions. That is to be preferred which gives the smallest curvature of the surfaces; because, since in our formulæ which determine the spherical aberration, some quantities are neglected, these are always greater when a large arch (that is, an arch of many degrees) is employed. No radius should be admitted which is much less than one third of the focal distance.

This process will be made plain by an example.

Experiments have shown, that in common crown-glass the sine of incidence is to the sine of refraction as 1·526 is to 1, and that in the generality of flint-glass it is as 1·604 to 1. Also that $\frac{dm}{dm'} = 0{\cdot}6054 = u$. Therefore $m - 1 = 0{\cdot}526$; $m' - 1 = 0{\cdot}604$; $c = \frac{m-1}{m'-1'} = 0{\cdot}87086$. By these numbers we can compute the co-efficients of our final equation. We shall find them as follows:

$A = 2{\cdot}012$, $B = 3{\cdot}529$, $C = 1{\cdot}360$, $D = -0{\cdot}526$, $E = 1{\cdot}8659$.

The general equation (p. 155, col. 1, line 16), when subjected to the assumed coincidence of the internal surfaces, is $\frac{A-C}{a^2} - \frac{B+D-2C}{a} + E + D - C = 0$. $A - C$ is $= 0{\cdot}652$, $B + D - 2C$ is $= 0{\cdot}283$, and $E + D - C$ is $= -0{\cdot}020$; and the equation with numerical co-efficients is $\frac{0{\cdot}652}{a^2} - \frac{0{\cdot}283}{a} - 0{\cdot}020 = 0$, which corresponds to the equation $px^2 + qx + r = 0$. We must now make $s = \frac{q}{p} = \frac{0{\cdot}283}{0{\cdot}652} = 0{\cdot}434$, and $t = \frac{r}{p} = \frac{0{\cdot}02}{0{\cdot}652} = 0{\cdot}0307$. This gives us the final quadratic equation $\frac{1}{a^2} - \frac{0{\cdot}434}{a} - 0{\cdot}0307 = 0$. To solve this, we have $-\frac{1}{2}s = 0{\cdot}217$, and $\frac{1}{4}s^2 = -0{\cdot}0471$. From this take t, which is $= -0{\cdot}0307$ (that is, to 0·0471 add 0·0307), and we obtain 0·0778, the square root of which is $= 0{\cdot}2789$. Therefore, finally, $\frac{1}{a} = 0{\cdot}2170 \pm 0{\cdot}2789$, which is either 0·4959 or $-0{\cdot}0619$. It is plain that the first must be preferred, because the second gives a negative radius, or makes the first surface of the crown-glass concave. Now as the convergence of the rays is to be produced by the crown-glass, the other surface must become very convex, and occasion great errors in the computed aberration. We therefore retain 0·4959 for the value of $\frac{1}{a}$, and $a = \frac{1}{0{\cdot}4959} = 2{\cdot}0166$.

To obtain b, use the equation $\frac{1}{b} = \frac{1}{a} - 1$, which gives $\frac{1}{b} = -0{\cdot}5041$, and therefore a convex surface. Therefore $b = \frac{1}{0{\cdot}5041} = 1{\cdot}9837$.

a' is the same with b, and $\frac{1}{a'} = -0{\cdot}5041$.

To obtain b', use the equation $\frac{1}{b'} = \frac{1}{a'} + u$. Now $u = 0{\cdot}6054$, and $\frac{1}{a'} = -0{\cdot}5041$. The sum of these is 0·1013; and since it is positive, the surface is concave. $b = \frac{1}{\cdot1013} = 9{\cdot}872$.

Lastly, $\frac{1}{P} = m - 1 - u\,(m' - 1) = 0{\cdot}1603$, and $P = \frac{1}{0{\cdot}1603} = 0{\cdot}2383$.

Now to obtain all the measures in terms of the focal distance P, we have only to divide the measures already found by 6·2383, and the quotients are the measures wanted.

Therefore $a = \frac{2{\cdot}0166}{6{\cdot}2383} = 0{\cdot}32325$,

$$b = \frac{1{\cdot}9837}{6{\cdot}2383} = -0{\cdot}31798,$$

$$a' = \;\text{--}\; = -0{\cdot}31798,$$

$$b' = \frac{9{\cdot}872}{6{\cdot}2383} = 1{\cdot}5825,$$

$$P = \;\text{--}\; = 1{\cdot}$$

If it be intended that the focal distance of the object-glass shall be any number n of inches or feet, we have only to multiply each of the above radii by n, and we have their lengths in inches or feet.

Thus we have completed the investigation of the construction of a double object-glass. Although this was intricate, the final result is abundantly simple for practice, especially with the assistance of logarithms. The only troublesome thing is the preparation of the numerical co-efficients A, B, C, D, E of the final equation. Strict attention must also be paid to the positive and negative signs of the quantities employed.

We might propose other conditions. Thus it is natural to prefer for the first or crown-glass lens such a form as shall give it the smallest possible aberration. This will require a small aberration of the flint-glass to correct it. But a little reflection will convince us that this form will not be good. The focal distance of the crown-glass must not exceed one third of that of the compound glass; these two being nearly in the proportion of $dm' - dm$ to dm'. Therefore if this form be adopted, and a be made about $\frac{1}{6}$th of b, it will not exceed $\frac{1}{3}$th of P. Therefore, although we may produce a most accurate union of the central and marginal rays by opposite aberrations, there will be a considerable aberration of some rays which are between the centre and the margin.

It is absolutely impossible to collect into one point the whole rays (though the very remotest rays are united with the central rays), except in a very particular case, which cannot obtain in an object-glass; and the small quantities which are neglected in the formula which we have given for the spherical aberration, produce errors which do not follow any proportion of the aperture that can be expressed by an equation of a manageable form. When the aperture is very large, it is better not to correct the aberration for the whole aperture, but for about $\frac{5}{6}$ths of it. When the rays corresponding to this distance are made to coincide with the central rays by means of opposite aberrations, the rays which are beyond this distance will be united with some of those which are nearer to the centre, and the whole diffusion will be considerably diminished. Dr Smith has illustrated this in a very perspicuous manner in his theory of his Catoptric Microscope.

But although we cannot adopt this form of an object-glass, there may be other considerations which may lead us to prefer some particular form of the crown-glass, or of the flint-glass. We shall therefore adopt our general equation $\frac{A}{a^2} - \frac{B}{a} - \frac{C}{a'^2} - \frac{D}{a'} + E = 0$ to this condition.

Therefore let h express this selected ratio of the two radii of the crown-glass, making $\frac{a}{b} = h$ (remembering always that a is positive and b negative in the case of a double convex, and h is a negative number).

With this condition we have $\frac{1}{b} = \frac{h}{a}$. But when we make n the unit of our formula of aberration, $\frac{1}{b} = \frac{1}{a} - 1$. Therefore $1 = \frac{1}{a} - \frac{h}{a}$, and $\frac{1}{a} = \frac{1}{1-h}$. Now substitute this for $\frac{1}{a}$ in the general equation, and change all the signs (which still preserves it $= 0$), and we obtain

$$\frac{\mathrm{C}}{a'^2}+\frac{\mathrm{D}}{a'}-\mathrm{E}-\frac{\mathrm{A}}{(1-h)^2}+\frac{\mathrm{B}}{1-h}=0.$$

By this equation we are to find $\frac{1}{a'}$, or the radius of the anterior surface of the flint-glass. The equation is of this form $px^2+qx+r=0$, and we must again make $s=\frac{q}{p}$ and $t=\frac{r}{p}$. Therefore $s=\frac{\mathrm{D}}{\mathrm{C}}$, and $t=\frac{1}{\mathrm{C}}\times\left(\frac{\mathrm{B}}{1-h}-\frac{\mathrm{A}}{(1-h)^2}-\mathrm{E}\right)$. Then, finally,

$$\frac{1}{a'}=-\tfrac{1}{2}s\pm\sqrt{\tfrac{1}{4}s^2-t}.$$

It may be worth while to take a particular case of this condition. Suppose the crown-glass to be of equal convexities on both sides. This has some advantages: we can tell with precision whether the curvatures are precisely equal, by measuring the focal distance of rays reflected back from its posterior surface. These distances will be precisely equal. Now it is of the utmost importance in the construction of an object-glass which is to correct the spherical aberration, that the forms be precisely such as are required by our formulæ.

In this case of a lens equally convex on both sides $\frac{1}{a}$ is $=-\frac{1}{b}=\frac{1}{2}$. Substitute this value for $\frac{1}{a}$ in the general equation $\frac{\mathrm{A}}{a^2}-\frac{\mathrm{B}}{a}-\frac{\mathrm{C}}{a'^2}-\frac{\mathrm{D}}{a'}+\mathrm{E}=0$, and then $\frac{\mathrm{A}}{a^2}=\frac{\mathrm{A}}{4}$; $\frac{\mathrm{B}}{a}$ becomes $\frac{\mathrm{B}}{2}$. Now change all the signs, and we have $\frac{\mathrm{C}}{a'^2}+\frac{\mathrm{D}}{a'}-\mathrm{E}-\frac{\mathrm{A}}{4}+\frac{\mathrm{B}}{2}=0$, by which we are to find a'. This in numbers is $\frac{1\cdot360}{a'}-\frac{0\cdot526}{a'}-0\cdot6044=0$. Then $s=\frac{-0\cdot526}{1\cdot360}=0\cdot3867$, and $t=\frac{-0\cdot6044}{1\cdot360}=-0\cdot4444$. Then $-\frac{1}{2}s=0\cdot1933$; $\frac{1}{4}s^2=0\cdot0374$; and $\sqrt{\frac{1}{4}\mathrm{S}^2-t}=\pm 0\cdot6941$; so that $\frac{1}{a'}=0\cdot1933\pm 0\cdot6941$. This gives two real roots, viz. 0·8874, and — 0·5008. If we take the first, we shall have a convex anterior surface for the flint-glass, and consequently a very deep concave for the posterior surface. We therefore take the second or negative root — 0·5008.

We find $\frac{1}{b'}$, as before, by the equation $\frac{1}{b'}=\frac{1}{a'}+u=0\cdot1046$, which will give a large value of b'.

We had $\frac{1}{a}=\frac{1}{2}$,

and $\frac{1}{b}=-\frac{1}{2}$,

and $\frac{1}{\mathrm{P}}$ is the same as in the former case, viz. 0·1603.

Having all these reciprocals, we may find a, b, a', b', and P; and then dividing them by P, we obtain finally

$$\begin{aligned} a &= 0\cdot3206, \\ b &= -0.3206, \\ a' &= -0\cdot3201, \\ b' &= 1\cdot533, \\ \mathrm{P} &= 1\cdot \end{aligned}$$

By comparing this object-glass with the former, we may remark, that diminishing a a little increases b, and in this respect improves the lens. It indeed has diminished b', but this being already considerable, no inconvenience attends the diminution. But we learn, at the same time, that the advantage *must* be very small; for we cannot diminish a much more, without making it as small as the smallest radius of the object-glass. This proportion is therefore very near the maximum, or best possible; and we know that in such cases even considerable changes in the radii will make but small changes in the result: for these reasons we are disposed to give a strong preference to the first construction, on account of the other advantages which we showed to attend it.

As another example, we may take a case which is very nearly the general practice of the London artists. The radius of curvature for the anterior surface of the convex crown-glass is $\frac{5}{6}$ths of the radius of the posterior surface, so that $h=\frac{5}{6}$. This being introduced into the determinate equation, gives

$$\begin{aligned} a &= 0\cdot2938, & a' &= -0\cdot3443, \\ b &= -0\cdot3526, & b &= 1\cdot1474. \end{aligned}$$

As another condition, we may suppose that the second or flint-glass is of a determined form.

This case is solved much in the same manner as the former. Taking h to represent the ratio of a' and b', we have $\frac{1}{a'}=\frac{1}{1-h}$. This value being substituted in the general equation $\frac{\mathrm{A}}{a^2}-\frac{\mathrm{B}}{a}-\frac{\mathrm{C}}{a'2}-\frac{\mathrm{D}}{a'}+\mathrm{E}=0$, gives us $\frac{\mathrm{A}}{a^2},-\frac{\mathrm{B}}{a}+\mathrm{E}-\frac{\mathrm{C}}{(1-h)^2}-\frac{\mathrm{D}}{1-h}=0$. This gives for the final equation $x^2+sx+t=0$, $s=\frac{\mathrm{B}}{\mathrm{A}}$, and $t=\frac{1}{\mathrm{A}}\times\left(\mathrm{E}-\frac{\mathrm{C}}{(1-h)^2}-\frac{\mathrm{D}}{1-h}\right)$, and $\frac{1}{a}=-\frac{1}{2}s\pm\sqrt{\frac{1}{4}s^2-t}$.

We might here take the particular case of the flint-glass being equally concave on both sides. Then, because $\frac{1}{n'}=-u$, and in the case of equal concavities $\frac{2}{a'}=\frac{1}{n'}=-u$, it is sufficient to put $-\frac{1}{2}u$ for $\frac{1}{a'}$. This being done, the equation becomes $\frac{\mathrm{A}}{a}-\frac{\mathrm{B}}{a}+\frac{\mathrm{C}u^2}{4}+\frac{\mathrm{D}u}{2}+\mathrm{E}=0$. This gives $s=\frac{\mathrm{B}}{\mathrm{A}}$, and $t=\frac{1}{\mathrm{A}}\cdot\left(\frac{4\,\mathrm{D}u-2\,\mathrm{C}u^2}{8}+\mathrm{E}\right)$.

We imagine that these cases are sufficient for showing the management of the general equation; and the example of the numerical solution of the first case affords instances of the only niceties which occur in the process, viz. the proper employment of the positive and negative quantities.

We have oftener than once observed, that the formula is not perfectly accurate, and that in very large apertures errors will remain. It is proper, therefore, when we have obtained the form of a compound object-glass, to calculate trigonometrically the progress of the light through it; and if we find a considerable aberration, either chromatic or spherical, remaining, we must make such changes in the curvatures as will correct it. We have done this for the first example; and we find, that if the focal distance of the compound object-glass be 100 inches, there remains of the spherical aberration nearly $\frac{1}{60}$th of an inch, and the aberration of colour is over corrected above $\frac{1}{9}$th of an inch. The first aberration has been diminished about six times, and the other about thirty times. Both of the remaining errors will be diminished by increasing the radius of the inner surfaces. This will diminish the aberration of the crown-glass, and will diminish the dispersion of the flint more than that of the crown. But indeed the remaining error is hardly worth our notice.

It is evident to any person conversant with optical discussions that we shall improve the correction of the spherical aberration by diminishing the refractions. If we employ two lenses for producing the convergency of the rays to a real focus, we shall reduce the aberration to $\frac{1}{4}$th. Therefore a better achromatic glass will be formed of three lenses, two of which are convex and of crown-glass. The refraction being thus divided between them, the aberrations are lessened. There is no occasion to employ two concave lenses of flint-glass; there is even an advantage in using one. The aberration being considerable, less of it will serve for correcting the aberration of the crown-glass, and therefore such a form may be selected as has little aberration. Some light is indeed lost by these two additional surfaces; but this is much more than compensated by the greater apertures which we can venture to give when the curvature of the surface is so much diminished. We proceed therefore to

The Construction of a Triple Achromatic Object-glass.

It is plain that there are more conditions to be assumed before we can render this a determinate problem, and that the investigation must be more intricate. At the same time it must give us a much greater variety of constructions, in consequence of our having more conditions necessary for giving the equation this determinate form. Our limits will not allow us to give a full account of all that may be done in this method. We shall therefore content ourselves with giving one case, which will sufficiently point out the method of proceeding. We shall then give the results in some other eligible cases, as rules to artists by which they may construct such glasses.

Let the first and second glasses be of equal curvatures on both sides; the first being a double convex of crown-glass, and the second a double concave of flint-glass.

Still making n the unit of our calculus, we have in the first place $a = -b = -a' = b'$. Therefore $\frac{1}{a'} - \frac{1}{b'} = -\left(\frac{1}{a} - \frac{1}{b}\right)$, or $\frac{1}{n'} = -\frac{1}{n} = -1$. Therefore the equation $\frac{m}{n} + \frac{dm'}{n'} + \frac{dm''}{n''} = 0$ becomes $u - 1 + \frac{u}{n''} = 0$, or $\frac{1}{n''} = \frac{1}{u} - 1$. Let us call this value u'.

We have $\frac{1}{p} = m - 1$; $\frac{1}{p'} = -(m' - 1)$; $\frac{1}{p''} = u'(m - 1)$; $\frac{1}{\mathrm{P}} = \frac{1}{p} + \frac{1}{p'} + \frac{1}{p''} = m - m' + u'(m - 1)$. And if we make $m' - m = \mathrm{C}$, we shall have $\frac{1}{\mathrm{P}} = -\mathrm{C} + u'(m - 1)$.

Also $\frac{1}{r'} = m - 1$; $\frac{1}{r''} = m - 1 - (m' - 1) = m - m' = -\mathrm{C}'$.

The equality of the two curvatures of each lens gives $\frac{1}{a} = \frac{1}{2n}$. Therefore $\frac{1}{a} = -\frac{1}{b} = -\frac{1}{a'} = \frac{1}{b'} = \frac{1}{2}$; and $\frac{1}{b''} = \frac{1}{a''} - \frac{1}{n''} = \frac{1}{a''} - u$.

Substituting these values in the equation (page 154, col. 2, paragraph 4), we obtain the three formulæ,

1. $$cm^2 - \tfrac{1}{2}c(2m + 1) + \frac{c(m + 2)}{4m}$$

2. $$-m'^2 + \tfrac{1}{2}(2m' + 1) - \frac{m' + 2}{4m'} + (3m' + 1)(m - 1) - \frac{2(m' + 1)(m - 1)}{m'} - \frac{(3m' + 2)(m - 1)^2}{m'}$$

3. $$cu'\,3m^2 - \frac{cu'^2(2m + 1)}{a''} + \frac{cu'(m + 2)}{ma''^2} - cc'u'^2(3m + 1) + \frac{4cc'u'(m + 1)}{ma''} + \frac{cc'^2u'(3m + 2)}{m} = 0.$$

Now, arrange these quantities according as they are co-efficients of $\frac{1}{a''^2}$ and of $\frac{1}{a''}$, or independent quantities. Let the co-efficient of $\frac{1}{a''^2}$ be A, that of $\frac{1}{a''}$ be B, and the independent quantity be C, we have

$$\mathrm{A} = \frac{cu'(m + 2)}{m},\quad \mathrm{B} = cu'^2(2m + 1) - \frac{4cc'u'(m + 1)}{m}, \text{ and}$$

$$\mathrm{C} = cm^2 + \frac{c(m + 2)}{4m} + \tfrac{1}{2}(2m' + 1) + (3m' + 1)(m - 1) + cu'^3m^2 + \frac{cc'^2u'(3m + 2)}{m} - \tfrac{1}{2}c(2m + 1) - m'^2 - \frac{m' + 2}{4m} - \frac{2(m' + 1)(m - 1)}{m'} - \frac{(3m' + 2)(m - 1)^2}{m'} - cc'u'^2(3m + 1).$$

Our equation now becomes $\frac{\mathrm{A}}{a''^2} - \frac{\mathrm{B}}{a''} + \mathrm{C} = 0$.

This reduced to numbers, by computing the values of the co-efficients, is $\frac{1{\cdot}312}{a''^2} - \frac{1{\cdot}207}{a''} - 0{\cdot}3257 = 0$.

This, divided by 1·312, gives $s = -0{\cdot}92$, and $t = -0{\cdot}2482$, $-\frac{1}{2}s = 0{\cdot}46$, $\frac{1}{4}s^2 = 0{\cdot}2116$, and $\sqrt{\frac{1}{4}s^2 - t} = \pm 0{\cdot}6781$.

And, finally, $\frac{1}{a''} = 0{\cdot}46 \pm 0{\cdot}6781$.

This has two roots, viz. 0·2181 and − 1·1381. The last would give a small radius, and is therefore rejected.

Now, proceeding with this value of $\frac{1}{a''}$ and the $\frac{1}{n''}$, we get the other radius b'', and then, by means of u', we get the other radius which is common to the four surfaces. Then, by $\frac{1}{\mathrm{P}} = \frac{1}{p''} - c'$, we get the value of P.

The radii being all on the scale of which u is the unit, they must be divided by P to obtain their value on the scale which has P for its unit. This will give us

$a = -b = -a' = b' = 0{\cdot}530$,
$a'' = 1{\cdot}215$,
$b'' = -0{\cdot}3046$,
$\mathrm{P} = 1{\cdot}$

This is not a very good form, because the last surface has too great curvature.

We thought it worth while to compute the curvatures for a case where the internal surfaces of the lenses coincide, in order to obtain the advantages mentioned on a former occasion. The form is as follows:

The middle lens is a double concave of flint-glass; the last lens is of crown-glass, and has equal curvatures on both sides. The following table contains the dimensions of the glasses for a variety of focal distances. The first column contains the focal distances in inches; the second contains the radii of the first surface in inches; the third contains the radii of the posterior surface of the first lens, and anterior surface of the second; and the fourth column has the radii of the three remaining surfaces.

We have had an opportunity of trying glasses of this construction, and found them equal to any of the same length, although executed by an artist by no means excellent in his profession as a glass-grinder. This very circumstance gave us the opportunity of seeing the good effects of interposing a transparent substance between the glasses. We put some clear turpentine varnish between them, which completely prevented all reflection from the internal surfaces. Accordingly these telescopes were surprisingly bright; and although the roughness left by the first grinding was very perceptible by the naked eye before the glasses were put together, yet when joined in this manner it entirely disappeared, even when the glasses were viewed with a deep magnifier.

The aperture of an object-glass of this construction, of 30 inches focal distance, was $3\frac{1}{5}$th inches, which is considerably more than any of Mr Dollond's that we have seen.

If we should think it of advantage to make all the three lenses isosceles, that is, equally curved on both surfaces, the general equation will give the following radii:

$$a = +\,0·639 \quad a' = -\,0·5285 \quad a'' = +\,0·6413$$
$$b = -\,0·639 \quad b' = +\,0·5285 \quad b'' = -\,0·6413.$$

This seems a good form, having large radii.

Should we choose to have the two crown-glass lenses isosceles and equal, we must make

$$a = +\,0·6412 \quad a' = -\,0·5227 \quad a'' = +\,0·6412$$
$$b = -\,0·6412 \quad b' = +\,0·5367 \quad b'' = -\,0·6412.$$

This form hardly differs from the last.

Our readers will recollect that all these forms proceed on certain measures of the refractive and dispersive powers of the substances employed, which are expressed by m, m', dm, and dm'; and we may be assured that the formulæ are sufficiently exact, by the comparison (which we have made in one of the cases) of the result of the formulæ and the trigonometrical calculation of the progress of the rays. The error was but $\frac{1}{60}$th of the whole, ten times less than another error, which unavoidably remains, and will be considered presently. These measures of refraction and dispersion were carefully taken; but there is great diversity, particularly in the flint-glass. We are well informed that the manufacture of this article has considerably changed of late years, and that it is in general less refractive and less dispersive than formerly. This must evidently make a change in the forms of achromatic glasses. The proportion of the focal distance of the crown-glasses to that of the flint must be increased, and this will occasion a change in the curvatures, which shall correct the spherical aberration. We examined with great care a parcel of flint-glass which an artist of this city got lately for the purpose of making achromatic object-glasses, and also some very white crown-glass made in Leith; and we obtained the following measures:

$$m = 1·529 \qquad \frac{dm}{dm'} = \frac{142}{219} = 0·64841.$$
$$m' = 1·578$$

We computed some forms for triple object-glasses made of these glasses, which we shall subjoin as a specimen of the variations which this change of data will occasion.

If all the three lenses are made isosceles, we have

$$a = +\,0·796 \quad a' = -\,0·474 \quad a'' = +\,0·502$$
$$b = -\,0·796 \quad b' = +\,0·474 \quad b'' = -\,0·502$$

or

$$a = \;\,0·504 \quad a' = -\,0·475 \quad a'' = +\,0·793$$
$$b = -\,0·504 \quad b' = \;\,0·475 \quad b'' = -\,0·793.$$

If the middle lens be isosceles, the two crown-glass lenses may be made of the same form and focal distance, and placed the same way. This will give us

$$a = +\,0·705 \quad a' = -\,0·475 \quad a'' = +\,0·705$$
$$b = -\,0·547 \quad b' = +\,0·475 \quad b'' = -\,0·547.$$

This construction allows a much better form, if the measures of refraction and dispersion are the same that we used formerly. For we shall have

$$a = +\,0·628 \quad a' = -\,0·579 \quad a'' = +\,0·628$$
$$b = -\,0·749 \quad b' = +\,0·579 \quad b'' = -\,0·749.$$

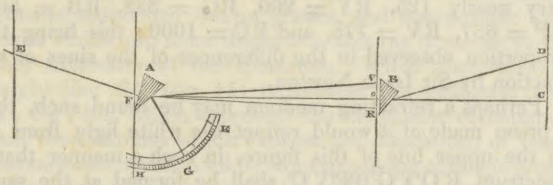
And this is pretty near the practice of the London opticians.

We may here observe, upon the whole, that an amateur has little chance of succeeding in these attempts. The diversity of glasses, and the uncertainty of the workman's producing the very curvatures which he intends, are so great, that the object-glass turns out different from our expectation. The artist who makes great numbers acquires a pretty certain guess at the remaining error; and having many lenses intended to be of one form, but unavoidably differing a little from it, he tries several of them with the other two, and finding one better than the rest, he makes use of it to complete the set.

The great difficulty in the construction is to find the exact proportion of the dispersive powers of the crown and flint glass. The crown is pretty constant; but there are hardly two pots of flint-glass which have the same dispersive power. Even if constant, it is difficult to measure it accurately; and an error in this greatly affects the instrument, because the focal distances of the lenses must be nearly as their dispersive powers. The method of examining this circumstance, which we found most accurate, was as follows:

The sun's light, or that of a brilliant lamp, passed through a small hole in a board, and fell on another board pierced also with a small hole. Behind this was placed a fine prism A (fig. 12), which formed a spectrum R*o*V on a screen pierced with a small hole. Behind this was placed a prism B of the substance under examination. The ray which was refracted by it fell on the wall at D, and the distance of its illumination from that point to C, on which an unrefracted ray would have fallen, was carefully measured. This showed the refraction of that colour. Then, in order that we might be certain that we always compared the refraction of the same precise colour by the different prisms placed at B, we marked the precise position of the prism A when the ray of a particular colour fell on the prism B. This was done by an index AG attached to A, and turning with it, when we caused the different colours of the spectrum formed by A to fall on B. Having examined one prism B with respect to all the colours in the spectrum formed by A, we put another B in its place. Then bringing A to all its former positions successively, by means of a graduated arch HGK, we were certain, that when the index was at the same division of the arch, it was the very ray which had been made to pass through the first prism B in a former experiment. We did not solicitously endeavour to find the very extreme red and violet rays; because, although we did not learn the whole dispersions of the two prisms, we learned their proportions, which is the circumstance wanted in the construction of achromatic glasses. It

Fig. 12.

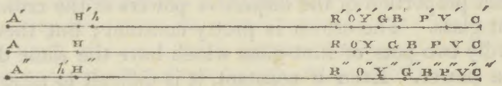


is in vain to attempt this by measuring the spectrums themselves; for we cannot be certain of selecting the very same colours for the comparison, because they succeed in an insensible gradation.

The intelligent reader will readily observe that we have hitherto proceeded on the supposition that when, by means of contrary refractions, we have united the extreme red and violet rays, we have also united all the others. But this is quite gratuitous. Sir Isaac Newton would however have made the same supposition; for he imagined that the different colours divided the spectrum formed by all substances in the proportions of a musical canon. This is a mistake. When a spectrum is formed by a prism of crown-glass, and another of precisely the same length is formed by the side of it by a prism of flint-glass, the confine between the green and blue will be found precisely in the middle of the first spectrum, but in the second it will be considerably nearer to the red extremity. In short, different substances do not disperse the colours in the same proportion.

The effect of this irrationality (so to call it) of dispersion, will appear plainly in the following manner: Let A (fig. 13) represent a spot of white solar light falling perpendicularly on a wall. Suppose a prism of common glass placed behind the hole through which the light is admitted, with its refracting angle facing the left hand. It will refract the beam of light to the right, and will at the same time disperse this heterogeneous light into its component rays, carrying the extreme red ray from A to R, the extreme orange from A to O, the extreme yellow from A to Y, &c. and will form the usual prismatic spectrum ROYGBPVC. If the whole length RC be divided into 1000 parts, we shall have (when the whole refraction AR is small) RO very nearly 125, $RY = 200$, $RG = 333$, $RB = 500$, $RP = 667$, $RV = 778$, and $RC = 1000$; this being the proportion observed in the differences of the sines of refraction by Sir Isaac Newton.

Fig. 13.

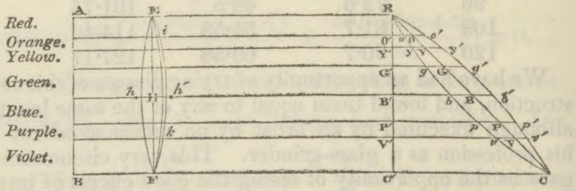


Perhaps a refracting medium may be found such, that a prism made of it would refract the white light from A′, in the upper line of this figure, in such a manner that a spectrum R′O′Y′G′B′P′V′C′ shall be formed at the same distance from A′, and of the same length, but divided in a different proportion. We do not know that such a medium has been found; but we know that a prism of flint-glass has its refractive and dispersive powers so constituted, that if A′H be taken about one third of AR, a spot of white light, formed by rays falling perpendicularly at H′, will be so refracted and dispersed that the extreme red ray will be carried from H′ to R′, and the extreme violet from H′ to C′, and the intermediate colours to intermediate points, forming a spectrum resembling the other, but having the colours more constipated towards R′, and more dilated towards C; so that the ray which the common glass carried to the middle point B of the spectrum RC is now in a point B′ of the spectrum R′C′, considerably nearer to R′.

Dr R. Blair found, on the other hand, that certain fluids, particularly such as contain the muriatic acid, when formed into a prism, will refract the light from H″ (in the lower line) so as to form a spectrum R″C″ equal to RC, and as far removed from A″ as RC is from A, but having the colours more dilated toward R″, and more constipated toward C, than is observed in RC; so that the ray which was carried by the prism of common glass to the middle point B, is carried to a point B″, considerably nearer to C″.

Let us now suppose that, instead of a white spot at A, we have a prismatic spectrum AB (fig. 14), and that the prism of common glass is applied, as before, immediately behind the prism which forms the spectrum AB. We know that this will be refracted sidewise, and will make a spectrum ROYGBPC, inclined to the plane of refraction in an angle of 45°; so that drawing the perpendicular RC′, we have $RC' = C'C$.

Fig. 14.



We also know that the prism of flint-glass would refract the spectrum formed by the first prism on EHF, in such a manner that the red ray will go to R, the violet to C, and the intermediate rays to points o, y, g, b, p, v, so situated that $O'o$ is $= R'O'$ of the other figure, Yy is $= R'Y'$ of that figure, $Gg = R'G'$, &c. These points must therefore lie in a curve R*oygbpv*C, which is convex towards the axis R′C′. In like manner, we may be assured that Dr Blair's fluid will form a spectrum R*o′y′g′b′p′v′*C, concave toward R′C.

Let it be observed, by the way, that this is a very good method for discovering whether a medium disperses the light in the same proportion with the prism which is employed for forming the first spectrum AB or EF. It disperses in the same or in a different proportion, according as the oblique spectrum is straight or crooked; and the exact proportion corresponding to each colour is found by measuring the ordinates of the curves R*b*C or R*b′*C.

Having formed the oblique spectrum RBC by a prism of common glass, we know that an equal prism of the same glass, placed in a contrary position, will bring back all the rays from the spectrum RBC to the spectrum AB, laying each colour on its former place.

In like manner, having formed the oblique spectrum R*b*C by a prism of flint-glass, we know that another prism of flint-glass, placed in the opposite direction, will bring all the rays back to the spectrum EHF.

But having formed the oblique spectrum RBC by a prism of common glass, if we place the flint-glass prism in the contrary position, it will bring the colour R back to E, and the colour C to F; but it will not bring the colour B to H, but to a point *h*, such that B*h* is equal to *b*H, and *b*B to *h*H. In like manner, the other colours will not be brought back to the straight line EHF, but to a curve E*h*F, forming a crooked spectrum.

In like manner, the fluids discovered by Dr Blair, when employed to bring back the oblique spectrum RBC formed by common glass, will bring its extremities back to E and F, and form the crooked spectrum E*h′*F lying beyond EHF.

This experiment evidently gives us another method for examining the proportionality of the dispersion of different substances.

Having, by common glass, brought back the oblique spectrum formed by common glass to its natural place AB, suppose the original spectrum at AB to contract gradually (as Newton has made it to do by means of a lens), it is plain that the oblique spectrum will also contract, and so will the second spectrum at AB; and it will at last coalesce into a white spot. The effect will be equivalent to a gradual compression of the whole figure, by which the parallel lines AR and BC gradually approach, and at last unite.

In like manner, when the oblique spectrum formed by flint-glass is brought back to EHF by a flint-glass prism, and the figure compressed in the same gradual manner, all the colours will coalesce into a white spot.

But when flint-glass is employed to bring back the oblique spectrum formed by common glass, it forms the crooked spectrum EhF. Now let the figure be compressed. The curve EhF will be doubled down on the line Hh, and there will be formed a compound spectrum Hh, quite unlike the common spectrum, being purple or claret coloured at H by the mixture of the extreme red and violet, and green edged with blue at h by the mixture of the green and blue. The fluid prisms would in like manner form a spectrum of the same kind on the other side of H.

This is precisely what is observed in achromatic object-glasses made of crown-glass and flint: for the refraction from A to R corresponds to the refraction of the convex crown-glass; and the contrary refraction from R to E corresponds to the contrary refraction of the concave flint-glass, which still leaves a part of the first refraction, producing a convergence to the axis of the telescope. It is found to give a purple or wine-coloured focus, and within this a green one, and between these an imperfect white. Dr Blair found, that when the eye-glass was drawn out beyond its proper distance, a star was surrounded by a green fringe, by the rays of the green end of the spectrum, which crossed each other within the focus; and when the eye-glass was too near the object-glass, the star had a wine-coloured fringe. The green rays were ultimately most refracted. We should expect the fringe to be of a blue colour rather than a green. But this is easily explained. The extreme violet rays are very faint, so as hardly to be sensible; therefore, when a compound glass is made as achromatic as possible to our senses, in all probability (nay certainly) these almost insensible violet rays are left out, and perhaps the extreme colours which are united are the red and the middle violet rays. This makes the green to be the mean ray, and therefore the most outstanding when the dispersions are not proportional.

Dr Blair very properly calls these spectrums, Hh and Hh', *secondary spectrums*, and seems to think that he is the first who has taken notice of them as indispensably necessary. But this subject was touched by Clairaut, and fully discussed by Boscovich.

The most essential service which the public has received at the hands of Dr Blair, is the discovery of fluid mediums of proper dispersive power. By composing the lenses of such substances, we are at once freed from the irregularities in the refraction and dispersion of flint-glass, from which the chemists have not been able to free it. In whatever way this glass is made, it consists of parts which differ both in refractive and dispersive power; and when taken up from the pot, these parts mix in threads, which may be disseminated through the mass in any degree of fineness. But they still retain their properties; and when a piece of flint-glass has been formed into a lens, the eye, placed in its focus, sees the whole surface occupied by glistening threads or broader veins running across it. Great rewards have been offered for removing this defect, but hitherto to no purpose. We beg leave to propose the following method. Let the glass be reduced to powder, and then melted with a great proportion of alkaline salt, so as to make a liquor silicum. When precipitated from this by an acid, it must be in a state of very uniform composition. If again melted into glass, we should hope that it would be free from this defect; if not, the case seems to be desperate. But by using a fluid medium, Dr Blair was released from all this embarrassment; and he acquired another immense advantage, that of adjusting at pleasure both the refractive and dispersive powers of his lenses. In solid lenses, we do not know whether we have taken the curvatures suited to the refractions till our glass is finished; and if we have mistaken the proportions, all our labour is lost. But when fluids are used, it is enough that we know nearly the refractions. We suit our focal distances to these, and then select our curvature, so as to remove the aberration of figure, preserving the focal distances. Thus, by properly tempering the fluid mediums, we bring the lens to agree precisely with the theory, perfectly achromatic, and the aberration of figure as much corrected as is possible.

Dr Blair examined the refractive and dispersive powers of a great variety of substances, and found great varieties in their actions on the different colours. This is indeed what every well-informed naturalist would expect. There is no doubt now among naturalists about the mechanical connection of the phenomena of nature; and all are agreed that the chemical actions of the particles of matter are perfectly like in kind to the action of gravitating bodies; that all these phenomena are the effects of forces like those which we call attractions and repulsions, and which we observe in magnets and electrified bodies; that light is refracted by forces of the same kind, but differing chiefly in the small extent of their sphere of activity. We cannot derive much knowledge from what he has already published, because it was chiefly with the intention of giving a popular, though not an accurate, view of the subject. The constructions which are there mentioned are not those which he found most effectual, but those which would be most easily understood, or demonstrated by the slight theory which is contained in the dissertation; besides, the manner of expressing the difference of refrangibility, perhaps chosen for its paradoxial appearance, does not give us a clear notion of the characteristic differences of the substances examined. Those rays which are ultimately most deflected from their direction, are said to have become the most refrangible by the combination of different substances, although in all the particular refractions by which this effect is produced, they are less refracted than the violet light. We can just gather this much, that common glass disperses the rays in such a manner that the ray which is in the confine of the green and blue occupies the middle of the prismatic spectrum; but in glasses, and many other substances which are more dispersive, this ray is nearer to the ruddy extremity of the spectrum. While therefore the straight line RC′ (fig. 14) terminates the ordinates Oo', YY′, Gg', &c., which represent the dispersion of common glass, the ordinates which express the dispersions of these substances are terminated by a curve passing through R and C′, but lying below the line RC′. When therefore parallel heterogeneous light is made to converge to the axis of a convex lens of common glass, as happens at F (in fig. 8) the light is dispersed, and the violet rays have a shorter focal distance. If we now apply a concave lens of greater dispersive power, the red and violet rays are brought to one focus F; but the green rays, not being so much refracted away from F, are left behind at φ, and have now a shorter focal distance. But Dr Blair afterwards found that this was not the case with the muriate acid, and some solutions in it. He found that the ray which common glass caused to occupy the middle of the spectrum, was much nearer to the blue extremity when refracted by these fluids. Therefore a concave lens formed of such fluids which united the red and violet rays in F′, refracted the green rays to f'.

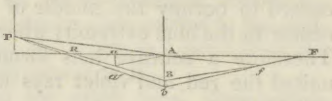
Having observed this, it was an obvious conjecture, that a mixture of some of these fluids might produce a medium, whose action on the intermediate rays should have the same proportion that is observed on common glass; or that two of them might be found which formed spectra similarly divided, and yet differing sufficiently in dispersive power to enable us to destroy the dispersion by contrary refractions, without destroying the whole refraction. Dr Blair accordingly found a mixture of ammoniacal and mercurial salts, and also some other substances, which produced dispersions proportional to that of glass, with respect to the different colours.

And thus did the result of this intricate and laborious investigation correspond to his utmost wishes. He produced achromatic telescopes which seem as perfect as the thing will admit of; for he was able to give them such apertures, that the *incorrigible* aberration arising from the spherical surfaces becomes a sensible quantity, so as to preclude farther amplification of the eye-glasses. We have examined one of his telescopes. The focal distance of the object-glass did not exceed 17 inches, and the aperture was fully 3½ inches. We viewed some single and double stars, and some common objects, with this telescope; and found, that in magnifying power, brightness, and distinctness, it was manifestly superior to one of Mr Dollond's of 42 inches focal length. It also gave us an opportunity of admiring the dexterity of the London artists, who could work the glasses with such accuracy. We had most distinct vision of a star when using an erecting eye-piece, which made this telescope magnify more than a hundred times; and we found the field of vision as uniformly distinct as with Dollond's 42-inch telescope magnifying forty-six times. The intelligent reader must admire the nice figuring and centring of the very deep eye-glasses which are necessary for this amplification.

We now proceed to consider the eye-pieces or glasses of telescopes. The proper construction of an eye-piece is not less essential than that of the object-glass. But our limits will not allow us to treat this subject in the same detail. Our readers will find abundant information in Dr Smith's Optics concerning the eye-glasses, chiefly deduced from Huyghens's fine theory of aberration. At the same time, we must again pay Mr Dollond the merited compliment of saying, that he was the first who made any scientific application of this theory to the compound eye-piece for erecting the object. His eye-pieces of five and six glasses are very ingenious reduplications of Huyghens's eye-pieces of two glasses, and would probably have superseded all others, had not his discovery of achromatic object-glasses caused opticians to consider the chromatic dispersion with more attention, and pointed out methods of correcting it in the eye-piece without any compound eye-glasses. They have found that this may be more conveniently done with four eye-glasses, without sensibly diminishing the advantages which Huyghens showed to result from employing many small refractions instead of a lesser number of great ones. As this is a curious subject, we shall add what may be sufficient for making our readers fully acquainted with it, and content ourselves with merely mentioning the principles of the other rules for constructing an eye-piece.

Such readers as are less familiarly acquainted with optical discussions will do well to keep in mind the following consequences of the general focal theorem.

Fig. 15.



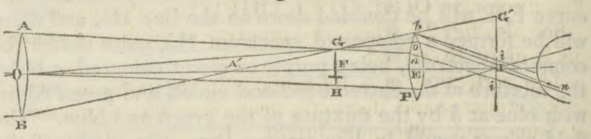
If AB (fig. 15) be a lens, R a radiant point or focus of incident rays, and a the focus of parallel rays coming from the opposite side; then,

1. Draw the perpendicular aa' to the axis, meeting the incident ray in a', and $a'A$ to the centre of the lens. The refracted ray BF is parallel to $a'A$; for $Ra' : a'A$ ($= Ra : aA$) $= RB : BF$ ($= RA : AF$), which is the focal theorem.

2. An oblique pencil BPb proceeding from any point P which is not in the axis, is collected to the point f, where the refracted ray BF cuts the line PAf drawn from P through the centre of the lens: for $Pa' : a'A = PB : Bf$, which is also the focal theorem.

The Galilean telescope is susceptible of so little improvement that we need not employ any time in illustrating its performance.

Fig. 16.



The simple astronomical telescope is represented in fig. 16. The beam of parallel rays, inclined to the axis, is made to converge to a point G, where it forms an image of the lowest point of a very distant object. These rays decussating from G fall on the eye-glass; the ray from the lowest point B of the object-glass falls on the eye-glass at b; and the ray from A falls on a; and the ray from the centre O falls on o. These rays are rendered parallel, or nearly so, by refraction through the eye-glass, and take the direction bi', oI, ai. If the eye be placed so that this pencil of parallel rays may enter it, they converge to a point of the retina, and give distinct vision to the lowest point of the object. It appears inverted, because the rays by which we see its lowest point come in the direction which in simple vision is connected with the upper point of an object. They come from above, and therefore are thought to proceed from above. We see the point as if situated in the direction Io. In like manner, the eye placed at I sees the upper point of the object in the direction IP, and its middle in the direction IE. The proper place for the eye is I; if brought much nearer the glass, or removed much farther from it, some or the whole of this extreme pencil of rays will not enter the pupil. It is therefore of importance to determine this point. Because the eye requires parallel rays for distinct vision, it is plain that F must be the principal focus of the eye-glass. Therefore, by the common focal theorem, $OF : OE = OE : OI$, or $OF : FE = OE : EI$.

The magnifying power being measured by the magnitude of the visual angle, compared with the magnitude of the visual angle with the naked eye, we have $\frac{oIp}{oOp}$ or $\frac{oIF}{oOF}$ for the measure of the magnifying power. This is very nearly $= \frac{OE}{EI}$ or $\frac{OF}{FI}$.

As the line OE, joining the centres of the lenses, and perpendicular to their surfaces, is called the axis of the telescope, so the ray OG is called the axis of the oblique pencil, being really the axis of the cone of light which has the object-glass for its base. This ray is through its whole course the axis of the oblique pencil; and when its course is determined, the amplification, the field of vision, the apertures of the glasses, are all determined. For this purpose we have only to consider the centre of the object-glass as a radical point, and trace the process of a ray from this point through the other glasses: this will be the axis of some oblique pencil.

It is evident, therefore, that the field of vision depends on the breadth of the eye-glass. Should we increase this, the extreme pencil will pass through I, because O and I are still the conjugate foci of the eye-glass. On the other hand, the angle resolved on for the extent or field of vision gives the breadth of the eye-glass.

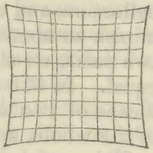
We may here observe, by the way, that for all optical instruments there must be two optical figures considered. The first shows the progress of a pencil of rays coming from one point of the object. The various focuses of this pencil show the places of the different images, real or virtual. Such a figure is formed by the three rays AGai, OGoI, BGbi. The second shows the progress of the axes of the different pencils proceeding through the centre of the object-glass. The focuses of this pencil of axes show the places where an image of the object-glass is formed; and this field determines the field of vision, the apertures of the lenses, and the amplification or magnifying power. The three rays OGoI, OFEI, OHPI, form this figure.

See also fig. 24, where the progress of both sets of pencils is more diversified.

The perfection of a telescope is to represent an object in its proper shape, distinctly magnified, with a great field of vision, and sufficiently bright. But there are limits to all these qualities; and an increase of one of them, for the most part, diminishes the rest. The brightness depends on the aperture of the object-glass, and will increase in the same proportion (because *ii'* will always be to AB in the proportion of EF to FO), till the diameter of the emergent pencil is equal to that of the pupil of the eye. Increasing the object-glass any more, can send no more light into the eye. But we cannot make the emergent pencil nearly so large as this when the telescope magnifies much; for the great aperture of the object-glass produces an indistinct image at GF, and its indistinctness is magnified by the eye-glass.

A great field of vision is incompatible with the true shape of the object; for it is not strictly true that all rays flowing from O are refracted to I. Those rays which go to the margin of the eye-glass cross the axis between E and I; and therefore they cross it at a greater angle than if they passed through I. Now had they really passed through I, the object would have been represented in its due proportions. Therefore, since the angles of the marginal parts are enlarged by the aberration of the eye-glass, the marginal parts themselves will appear enlarged, or the object appear distorted. Thus a chess-board viewed through a reading glass appears drawn out at the corners, and the straight lines are all changed into curves, as is represented in fig. 17.

Fig. 17.

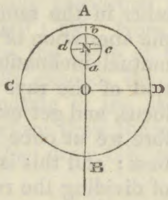


The circumstance which most peremptorily limits the extent of field is the necessary distinctness. If the vision be indistinct, it is useless, and no other quality can compensate this defect. The distortion is very inconsiderable in much larger angles of vision than we can admit, and is unworthy of the attention paid to it by optical writers. They have been induced to take notice of it, because the means of correcting it in a considerable degree are attainable, and afford an opportunity of exhibiting their knowledge; whereas the indistinctness which accompanies a large field is a subject of most difficult discussion, and has hitherto baffled all their efforts to express it by any intelligible or manageable formulæ.

This subject must however be considered. The image at GF of a very remote object is not a plain surface perpendicular to the axis of the telescope, but is nearly spherical, having O for its centre. If a number of pencils of parallel rays crossing each other in I fall on the eye-glass, they will form a picture on the opposite side, in the focus F. But this picture will by no means be flat, nor nearly so, but very concave towards E. Its exact form is of most difficult investigation. The elements of it are given by Dr Barrow; and we have given the chief of them in the article Optics, when considering the foci of infinitely slender pencils of oblique rays. Therefore it is impossible that the picture formed by the object-glass can be seen distinctly in all its parts by the eye-glass. Even if it were flat, the points G and H (fig. 16) are too far from the eye-glass when the middle F is at the proper distance for distinct vision. When, therefore, the telescope is so adjusted that we have distinct vision of the middle of the field, in order to see the margin distinctly we must push in the eye-glass: and having so done, the middle of the field becomes indistinct. When the field of vision exceeds twelve or fifteen degrees, it is not possible by any contrivance to make it tolerably distinct all over; and we must turn the telescope successively to the different parts of the field that we may see them agreeably.

The cause of this indistinctness is, as we have already said, the shortness of the lateral foci of lateral and oblique pencils refracted by the eye-glass. The oblique pencil *bGa*, by which an eye placed at I sees the point G of the image, is a cone of light, having a circular base on the eye-glass, of which circle *ab* is one of the diameters. There is a diameter perpendicular to this, which, in this figure, is represented by the point *o*. Fig. 18 represents the base of the cone as seen by an eye placed in the axis of the telescope, with the object-glass as appearing behind it. The point *b* is formed by a ray which comes from the lowest point B of the object-glass, and the point *a* is illuminated by a ray from A. The point *c* at the right hand of the circular base of this cone of light came from the point C on the left side of the object-glass; and the light comes to *d* from D. Now the laws of optics demonstrate, that the rays which come through the points *c* and *d* are more convergent after refraction than the rays which come through *a* and *b*. The analogies, therefore, which ascertain the foci of rays lying in planes passing through the axis, do not determine the foci of the others. Of this we may be sensible by looking through a lens to a figure on which are drawn concentric circles crossed by radii. When the telescope is so adjusted that we see distinctly the extremity of one of the radii, we shall not see distinctly the circumference which crosses the extremity with equal distinctness, and *vice versa*. This difference, however, between the foci of the rays which come through *a* and *b*, and those which come through *c* and *d*, is not considerable in the fields of vision which are otherwise admissible. But the same difference of foci obtains also with respect to the dispersion of light, and is more remarkable. Both D'Alembert and Euler have attempted to introduce it into their formulæ; but they have made them useless for any practical purpose by their inextricable complication.

Fig. 18.



This must serve as a general indication of the difficulties which occur in the construction of telescopes, even although the object-glass were perfect, forming an image without the smallest confusion or distortion.

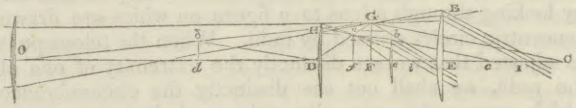
There is yet another difficulty or imperfection. The rays of the pencil *aGb* (fig. 16), when refracted through the eye-glass, are also separated into their component colours. The edge of the lens must evidently perform the office of a prism, and the white ray G*b* will be so dispersed, that if *bi* be the path of its red ray, the violet ray, which makes another part of it, will take such a course *bn* that the angle *i'bn* will be nearly $\frac{1}{27}$th of G'*bi'*. The ray G*a* passing through a part of the lens whose surfaces are less inclined to each other, will be less refracted, and will be less dispersed in the same proportion very nearly. Therefore the two violet rays will be very nearly parallel when the two red rays are rendered parallel.

Hence it must happen that the object will appear bordered with coloured fringes. A black line seen near the margin on a white ground, will have a ruddy and orange border on the outside, and a blue border within: and this confusion is altogether independent on the object-glass, and is so much the greater as the visual angle *b*IE is greater.

Such are the difficulties. They would be unsurmountable, were it not that some of them are so connected that, to a certain extent, the diminution of one is accompanied by a diminution of the other. What are called the *caustic curves* are the geometrical loci of the foci of infinitely slender pencils; consequently the point G is very nearly in the caustic formed by a beam of light consisting of rays parallel to I*o*, and occupying the whole surface of the eye-glass, because the pencil of rays which are collected at G is very small. Any thing therefore that diminishes the mutual inclination of the adjoining rays, puts their concourse farther off. Now this is precisely what we want; for the point G of the image formed by the object-glass is already beyond the focus of the oblique slender pencil of parallel rays *ia* and *i'b*; and therefore, if we could make this focus go a little farther from *a* and *b*, we shall bring it nearer to G, and obtain more distinct vision of this point of the object. Now let it be recollected, that in moderate refractions through prisms, two rays which are inclined to each other in a small angle are, after refraction, inclined to each other in the same angle. Therefore, if we can diminish the aberration of the ray *ai*, or *o*I, or *bi'*, we diminish their mutual inclination, and consequently the mutual inclination of the rays G*a*, G*o*, G*b'*, and therefore lengthen the focus, and get more distinct vision of the point G. Therefore we at once correct the distortion and the indistinctness; and this is the aim of Mr Huyghens's great principle of dividing the refractions.

The general method is as follows. Let O be the object-glass (fig. 19) and E the eye-glass of a telescope, and F their common focus, and FG the image formed by the object-glass. The proportion of their focal distances is supposed to be such as gives as great a magnifying power as the perfection of the object-glass will admit. Let BI be the axis of the emergent pencil. It is known by the focal theorem that GE is parallel to BI: therefore BGE is the whole refraction or deflection of the ray OHB from its former direction. Let it be proposed to diminish the aberrations by dividing this into two parts by means of two glasses D and *e*, so as to make the ultimate angle of vision *bic* equal to BIE, and thus retain the same magnifying power and visible field. Let it be proposed to divide it into the parts BGC and CGE.

Fig. 19.



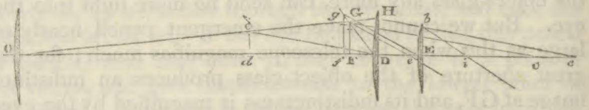
From G draw any line GD to the axis towards O; and draw the perpendicular DH, cutting OG in H; draw H*c* parallel to GC, cutting GD in *g*; draw *gf* perpendicular to the axis, and *ge* parallel to GE; draw *eb* perpendicular to the axis; draw Dδ parallel to GC, and *d*δ perpendicular to the axis. Then if there be placed at D a lens whose focal distance is D*d*, and another at *e* whose focal distance is *ef*, the thing is done. The ray OH will be refracted into H*b*, and this into *bi*, parallel to BI.

The demonstration of this construction is so evident by means of the common focal theorem, that we need not repeat it, nor the reasons for its advantages. We have the same magnifying power, and the same field of vision; we have less aberration, and therefore less distortion and indistinctness; and this is brought about by a lens HD of a smaller aperture and a greater focal distance than BE. Consequently, if we are contented with the distinctness of the margin of the field with a single eye-glass, we may greatly increase the field of vision; for if we increase DH to the size of EB, we shall have a greater field, and much greater distinctness in the margin; because HD is of a longer focal distance, and will bear a greater aperture, preserving the same distinctness at the edge. On this account the glass HD is commonly called the *field-glass*.

It must be observed here, however, that although the distortion of the object is lessened, there is a real distortion produced in the image *fg*. But this, when magnified by the glass *e*, is smaller than the distortion produced by the glass E, of greater aperture and shorter focus, on the undistorted image GF. But because there is a distortion in the second image *fg*, this construction cannot be used for the telescopes of astronomical quadrants, and other graduated instruments, because then equal divisions of the micrometer would not correspond to equal angles.

But the same construction will answer in this case by taking the point D on that side of F which is remote from O (fig. 20). This is the form now employed in the telescopes of all graduated instruments.

Fig. 20.



The exact proportion in which the distortion and the indistinctness at the edges of the field are diminished by this construction, depends on the proportion in which the angle BGE is divided by GC, and is of pretty difficult investigation. But it never deviates far (never one eighth in optical instruments) from the proportion of the squares of the angles. We may, without any sensible error, suppose it in this proportion. This gives us a practical rule of easy recollection, and of most extensive use. When we would diminish an aberration by dividing the whole refraction into two parts, we shall do it most effectually by making them equal. In like manner, if we divide it into three parts by means of two additional glasses, we must make each $= \frac{1}{3}$ of the whole, and so on for a greater number.

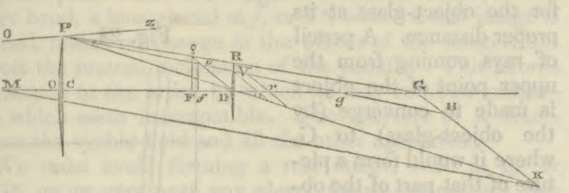
This useful problem, even when limited, as we have done, to equal refractions, is as yet indeterminate; that is, susceptible of an infinity of solutions; for the point D, where the field-glass is placed, was taken at pleasure; yet there must be situations more proper than others. The aberrations which produce distortion, and those which produce indistinctness, do not follow the same proportions. To correct the indistinctness, we should not select such positions of the lens HD as will give a small focal distance to *be*; that is, we should not remove it very far from F. Huyghens recommends the proportion of three to one for that of the focal distances of the lens HD and *eb*, and says that the distance D*e* should be $= 2\mathrm{F}e$. This will make $ei = \frac{1}{2}$ *e*F, and will divide the whole refraction into two equal parts, as any one will readily see by constructing the common optical figure. Mr Short, the celebrated improver of reflecting telescopes, generally employed this proportion; and we shall presently see that it is a very good one.

It has already been observed that the great refractions which take place on the eye-glasses, occasion very considerable dispersions, and disturb the vision by fringing every thing with colours. To remedy this, achromatic eye-glasses may be employed, constructed by the rules already delivered. This construction, however, is incomparably more intricate than that of object-glasses; for the equations must involve the distance of the radiant point, and be more complicated; and this complication is immensely increased on account of the great obliquity of the pencils.

Most fortunately the Huyghenian construction of an eye-piece enables us to correct this dispersion to a great degree of exactness. A heterogeneous ray is dispersed at H, and the red ray belonging to it falls on the lens *be*, at a greater distance from the centre than the violet ray coming from H. It will therefore be less refracted, *cæteris paribus*, by the lens *be*; and it is possible that the difference may be such that the red and violet rays dispersed at H may be rendered parallel at *b*, or even a little divergent, so as to unite accurately with the red ray at the bottom of the eye. How this may be effected by a proper selection of the places and figures of the lenses, will appear by the following proposition, which we imagine is new, and not inelegant.

Let the compound ray OP (fig. 21) be dispersed by the lens PC, and let PV, PR be its violet and red rays, cutting the axis in *g* and G. It is required to place another lens RD in their way, so that the emergent rays R*r*, V*v*, shall be parallel.

Fig. 21.



Produce the incident ray OP to Z. The angles ZPR, ZPV, are given $\left(\text{and RPV is nearly} = \frac{\text{ZPR}}{27}\right)$, and the intersections G and *g* with the axis. Let F be the focus of parallel red light coming through the lens RD in the opposite direction. Then (by the common optical theorem) the perpendicular Fϱ will cut PR in such a point ϱ, that ϱF will be parallel to the emergent ray R*r*, and to V*v*. Therefore if ϱD cut PV in *u*, and *uf* be drawn perpendicular to the axis, we shall have (also by the common theorem) the point *f* for the focus of violet rays, and $\text{DF} : \text{D}f = \text{D}\varrho : \text{D}u = 28 : 27$ nearly, or in a given ratio.

The problem is therefore reduced to this, "to draw from a point D in the line CG a line Dϱ, which shall be cut by the lines PR and PV in the given ratio."

The following construction naturally offers itself. Make $\text{GM} : g\text{M}$ in the given ratio, and draw MK parallel to P*g*. Through *any* point D of CG draw the straight line PDK, cutting MK in K. Join GK, and draw Dϱ parallel to KG. This will solve the problem; and, drawing ϱF perpendicular to the axis, we shall have F for the focus of the lens RD for parallel red rays.

The demonstration is evident; for MK being parallel to P*g*, we have $\text{GM} : g\text{M} = \text{GK} : \text{HK} = \varrho\,\text{D} : u\text{D} = \text{FD}f\text{D}$, in the ratio required.

This problem admits of an infinity of solutions, because the point D may be taken anywhere in the line CG. It may therefore be subjected to such conditions as may produce other advantages.

1. It may be restricted by the magnifying power, or by the division which we choose to make of the whole refraction which produces this magnifying power. Thus, if we have resolved to diminish the aberrations by making the two refractions equal, we have determined the angle R*r*D. Therefore draw GK, making the angle MGK equal to that which the emergent pencil must make with the axis, in order to produce this magnifying power. Then draw MK parallel to P*g*, meeting GK in K. Then draw PK, cutting the axis in D, and Dϱ parallel to GK, and ϱF perpendicular to the axis. D is the place and DF the focal distance of the eye-glass.

2. Particular circumstances may cause us to fix on a particular place D, and we only want the focal distance. In this case the first construction suffices.

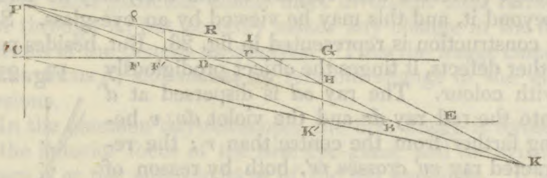
3. We may have determined on a certain focal distance DF, and the place must be determined. In this case let

$$\begin{array}{lrl} & \text{GF} : \text{F}\varrho & = 1 : \tan. \text{G}, \\ & \text{F}\varrho : fu & = 1 : m, \text{ m being} = \tfrac{27}{28}, \\ & fu : fg & = \tan. g : 1; \\ \text{then} & \text{GF} : fg & = \tan. g : m \tan. \text{G}; \\ \text{then} & \text{GF} - fg : \text{GF} & = \tan. g - m \tan. \text{G} : \tan. g, \\ \text{or} & \text{G}g + \text{F}f : \text{GF} & = \tan. g - m \tan. \text{G} : \tan. g, \end{array}$$

and $$\text{GF} = \text{G}g + \text{F}f\frac{\tan. g}{\tan. g - m \tan. \text{G}},$$ and is therefore given, and the place of F is determined; and since FD is given by supposition, D is determined.

The application of this problem to our purpose is difficult, if we take it in the most general terms; but the nature of the thing makes such limitations that it becomes very easy. In the case of the dispersion of light, the angle GP*g* is so small that MK may be drawn parallel to PG without any sensible error. If the ray OP were parallel to CG, then G would be the focus of the lens PC, and the point M would fall on C; because the focal distance of red rays is to that of violet rays in the same proportion for every lens, and therefore $\text{CG} : \text{C}g = \text{DF} : \text{D}f$. Now, in a telescope which magnifies considerably, the angle at the object-glass is very small, and CG hardly exceeds the focal distance; and CG is to C*g* very nearly in the same proportion of 28 to 27. We may therefore draw through C (fig. 22) a line CK parallel to PG; then draw GK′ perpendicular to the axis of the lenses, and join PK′; draw K′BE parallel to CG, cutting PK in B; draw BHI parallel to GK, cutting GK′ in H. Join HD and PK. It is evident that CG is bisected in F′, and that $\text{K}'\text{B} = 2\text{F}'\text{D}$; also $\text{K}'\text{H} : \text{HG} = \text{K}'\text{B} : \text{BE} = \text{CD} : \text{DG}$. Therefore DH is parallel to CK′ or to PG. But because $\text{PF}' = \text{F}'\text{K}'$, PD is $=$ DB, and $\text{IH} = \text{HB}$. Therefore $\varrho\text{D} = \text{HB}$, and $\text{FD} = \text{K}'\text{B} = 2\text{F}'\text{D}$; and FD is bisected in F′. Therefore

Fig. 22.



$$\text{CD} = \frac{\text{CG} + \text{FD}}{2}.$$

That is, in order that the eye-glass RD may correct the dispersion of the field-glass PC, *the distance between them must be equal to the half sum of their focal distances* very nearly. More exactly, *the distance between them must be equal to the half sum of the focal distance of the eye-glass, and the distance at which the field-glass would form an image of the object-glass.* For the point G is the focus to which a ray coming from the centre of the object-glass is refracted by the field-glass.

This is a very simple solution of an important problem. Huyghens's eye-piece corresponds with it exactly. If indeed the dispersion at P is not entirely produced by the refraction, but perhaps combined with some previous dispersion, the point M (fig. 21) will not coincide with C (fig. 22), and we shall have GC to GM as the natural dispersion at P to the dispersion which really obtains there. This may destroy the equation $\text{CD} = \frac{\text{CG} + \text{FD}}{2}$.

Thus, in a manner rather unexpected, have we freed the eye-glasses from the greatest part of the effect of dispersion. We may do it entirely by pushing the eye-glass a little nearer to the field-glass. This will render the violet rays a little divergent from the red, so as to produce a perfect picture at the bottom of the eye. But by doing so we have hurt the distinctness of the whole picture, because F is not in the focus of RD. We remedy this by drawing both glasses out a little, and the telescope is made perfect.

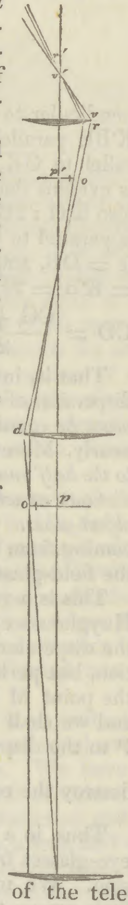
This improvement cannot be applied to the construction of quadrant telescopes, such as fig. 20. Mr Ramsden has attempted it, however, in a very ingenious way, which merits a place here, and is also instructive in another respect. The field-glass HD is a plano-convex, with its plane side next the image GF. It is placed very near this image. The consequence of this disposition is, that the image GF produces a vertical image *gf*, which is much less convex towards the glass. He then places a lens on the point C, where the red ray would cross the axis. The violet ray will pass on the other side of it. If the focal distance of this glass be *fc*, the vision will be distinct and free from colour. It has, however, the inconvenience of obliging the eye to be close to the glass, which is very troublesome.

This would be a good construction for a magic lanthorn, or for the object-glass of a solar microscope, or indeed of any compound microscope.

We may presume that the reader is now pretty familiar with the different circumstances which must be considered in the construction of an eye-piece, and proceed to consider those which must be employed to erect the object.

This may be done by placing the lens which receives the light from the object-glass in such a manner that a second image (inverted with respect to the first) may be formed beyond it, and this may be viewed by an eye-glass. Such a construction is represented in fig. 23. But, besides many other defects, it tinges the object prodigiously with colour. The ray *od* is dispersed at *d* into the red ray *dr* and the violet *dv*, *v* being farther from the centre than *r*; the refracted ray *vv'* crosses *rr'*, both by reason of spherical aberration and its greater refrangibility.

Fig. 23.

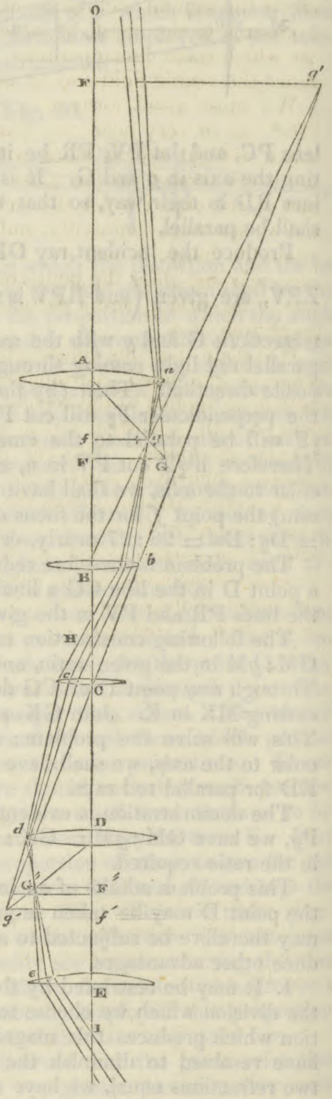


But the common day-telescope, invented by F. Rheita, has in this respect greatly the advantage of the one now described. The rays of compound light are dispersed at two points. The violet ray in its course falls without the red ray, but is accurately collected with it at a common focus, as we shall demonstrate by and by. Since they cross each other in the focus, the violet ray must fall within the red ray, and be less refracted than if it had fallen on the same point with the red ray. Had it fallen there, it would have separated from it; but by a proper diminution of its refraction, it is kept parallel to it, or nearly so. And this is one excellence of this telescope; when constructed with three eye-glasses perfectly equal, the colour is sensibly diminished, and by using an eye-glass somewhat smaller it may be removed entirely. We say no more of it at present, because we shall find its construction included in another, which is still more perfect.

It is evident at first sight that this telescope may be improved by substituting for the eye-glass the Huyghenian double eye-glass, or field-glass and eye-glass represented in figs. 19 and 20, and that the first of these may be improved and rendered achromatic. This will require the two glasses to be increased from their present dimensions to the size of a field-glass suited to the magnifying power of the telescope, supposing it an astronomical telescope. Thus we shall have a telescope of four eye-glasses. The first three will be of a considerable focal distance, and two of them will have a common focus at *b*. But this is considerably different from the eye-pieces of four glasses which are now used, and are far better. We are indebted for them to Mr Dollond, who was a mathematician as well as an artist, and in the course of his research discovered resources which had not been thought of. He had not then discovered the achromatic object-glass, and was busy in improving the eye-glasses by diminishing their spherical aberration. His first thought was to make the Huyghenian addition at both the images of the day-telescope. This suggested to him the following eye-piece of five glasses.

Fig. 24 represents this eye-piece, but there is not room for the object-glass at its proper distance. A pencil of rays coming from the upper point of the object is made to converge (by the object-glass) to G, where it would form a picture of that part of the object. But it is intercepted by the lens A*a*, and its axis is bent towards the axis of the telescope in the direction *ab*. At the same time, the rays which converged to G converge to *g*, and there is formed an inverted picture of the object at *gf*. The axis of the pencil is again refracted at *b*, crosses the axis of the telescope in H, is refracted again at *c*, at *d*, and at *e*, and at last crosses the axis in I. The rays of this pencil, diverging from *g*, are made less diverging, and proceed as if they came from *g'*, in the line B*gg'*. The lens *c*C causes them to converge to *g'*, in the line G″C*g'*. The lens *d*D makes them converge still more to G″, and there they form an erect picture G″F″; diverging from G″, they are rendered parallel by the refraction at *e*.

Fig. 24.



At H the rays are nearly parallel. Had the glass B*b* been a little farther from A, they would have been accurately so, and the object-glass, with the glasses A and B, would have formed an astronomical telescope with the Huyghenian eye-piece. The glasses C, D, and E, are intended merely for bending the rays back again till they again cross the axis in I. The glass C tends chiefly to diminish the great angle BH*b*; and then the two glasses D and E are another Huyghenian eye-piece.

The art in this construction lies in the proper adjustment of the glasses, so as to divide the whole bending of the pencil pretty equally among them, and to form the last image in the focus of the eye-glass, and at a proper distance from the other glass. Bringing B nearer to A would bend the pencil more to the axis. Placing C farther from B would do the same thing; but this would be accompanied with more aberration, because the rays would fall at a greater distance from the centres of the lenses. The greatest bending is made at the field-glass D; and we imagine that the telescope would be improved, and made more distinct at the edges of the field, by employing another glass of great focal distance between C and D.

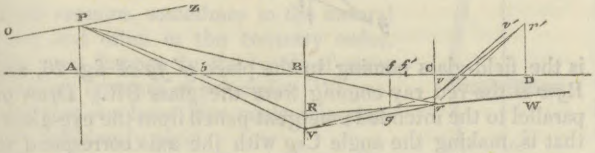
There is an image formed at H of the object-glasses, and the whole light passes through a small circle in this place. It is usual to put a plate here pierced with a hole which has the diameter of this image. A second image of the object-glass is formed at I, and indeed wherever the pencils cross the axis. A lens placed at H makes no change in any of the angles, nor in the magnifying power, and affects only the place where the images are formed. And, on the other hand, a lens placed at f, or F'', where a real image is formed, makes no change in the places of the images, but affects the mutual inclination of the pencils. This affords a resource to the artist, by which he may combine properties which seem incompatible. The aperture of A determines the visible field and all the other apertures.

We must avoid forming a real image, such as fg, or $F''G''$, on or very near any glass; for we cannot see this image without seeing along with it every particle of dust and every scratch on the glass. We see them as making part of the object when the image is exactly on the glass, and we see them confusedly, and so as to confuse the object, when the image is near it. For when the image is on or very near any glass, the pencil of light occupies a very small part of its surface, and a particle of dust intercepts a great proportion of it.

It is plain that this construction will not do for the telescope of graduated instruments, because the micrometer cannot be applied to the second image fg, on account of its being a little distorted, as has been observed of the Huyghenian eye-piece. Also the interposition of the glass C makes it difficult to correct the dispersion.

By proper reasoning from the correction in the Huyghenian eye-piece, we are led to the best construction of one with three glasses, which we shall now consider, taking it in a particular form, which shall make the discussion easy, and make us fully masters of the principles which lead to a better form. Therefore let PA (fig. 25) be the glass which first receives the light proceeding from the image formed by the object-glass, and let OP be the axis of the extreme pencil. This is refracted into PR, which is again refracted into Rr by the next lens Br. Let b be the focus of parallel rays of the second lens. Draw PBr. We know that $Ab : bB = PB : Br$, and that rays of one kind diverging from P will be collected at r. But if PR, PV be a red and a violet ray, the violet ray will be more refracted at V, and will cross the red ray in some intermediate point g of the line Rr. If therefore the first image had been formed precisely on the lens PA, we should have a second image at fg free from all coloured fringes.

Fig. 25.



If the refractions at P and R are equal (as in the common day-telescope), the dispersion at V must be equal to that at P, or the angle $vVr =$ VPR. But we have ultimately $RPV : RrV = BC : AB$ ($= Bb : Ab$ by the focal theorem). Therefore $gVr : grV$ (or $gr : gV$, or $Cf : fB$) $= Bb : Ab$, and $AB : Ab = Rr : Rg$.

This shows, by the way, the advantage of the common day-telescope. In this $AB = 2Ab$, and therefore f is the place of the last image which is free from coloured fringes. But this image will not be seen free from coloured fringes through the eye-glass Cr if f be its focus: for had gr, gv been both red rays, they would have been parallel after refraction; but gv being a violet ray, will be more refracted. It will not indeed be so much deflected from parallelism as the violet ray, which naturally accompanies the red ray to r, because it falls nearer the centre. By computation its dispersion is diminished about $\frac{1}{7}$th.

In order that gv may be made parallel to gr after refraction, the refraction at r must be such that the dispersion corresponding to it may be of a proper magnitude. How to determine this is the question. Let the dispersion at g be to the dispersion produced by the refraction at r (which is required for producing the intended magnifying power) as 1 to 9. Make $9 : 1 = ff' : f'C = fC : CD$, and draw the perpendicular Dr' meeting the refracted ray rr' in r'. Then we know by the common focal theorem, that if f' be the focus of the lens Cr, red rays diverging from g will be united in r'. But the violet ray gv will be refracted into vv' parallel to rr'. For the angle $vr'r : vgr =$ (ultimately) $fC : CD = 9 : 1$. Therefore the angle $vr'r$ is equal to the dispersion produced at r, and therefore equal to $r'vv'$, and vv' is parallel to rr'.

But by this we have destroyed the distinct vision of the image formed at fg, because it is no longer at the focus of the eye-glass. But distinct vision will be restored by pushing the glasses nearer to the object-glass. This makes the rays of each particular pencil more divergent after refraction through A, but scarcely makes any change in the directions of the pencils themselves. Thus the image comes to the focus f', and makes no sensible change in the dispersions.

In the common day-telescope, the first image is formed in the anterior focus of the first eye-glass, and the second image is at the anterior focus of the last eye-glass. If we change this last for one of half the focal distance, and push in the eye-piece till the image formed by the object-glass is half way between the first eye-glass and its focus, the last image will be formed at the focus of the new eye-glass, and the eye-piece will be achromatic. This is easily seen by making the usual computations by the focal theorem. But the visible field is diminished, because we cannot give the same aperture as before to the new eye-glass; but we can substitute for it two eye-glasses like the former, placed close together. This will have the same focal distance with the new one, and will allow the same aperture that we had before.

On these principles may be demonstrated the correction of colour in eye-pieces with three glasses of the following construction.

Let the glasses A and B be placed so that the posterior focus of the first nearly coincides with the anterior focus of the second, or rather so that the anterior focus of B may be at the place where the image of the object-glass is formed, by which situation the aperture necessary for transmitting the whole light will be the smallest possible. Place the third, C, at a distance from the second, which exceeds the sum of their focal distances by a space which is a third proportional to the distance of the first and second, and the focal distance of the second. The distance of the first eye-glass from the object-glass must be equal to the product of the focal distance of the first and second divided by their sum.

Let Oo, Aa, Bb, Cc, the focal distances of the glasses, be O, a, b, c. Then make $AB = a + b$ nearly; $BC = b + c + \frac{b^2}{b+c}$; $OA = \frac{bc}{b+c}$. The amplification or magnifying power will be $= \frac{ob}{ac}$, the equivalent eye-glass $= \frac{ac}{b}$, and the field of vision $= 3438' \times \frac{\text{aperture of A}}{\text{foc. dist. ob. gl.}}$.

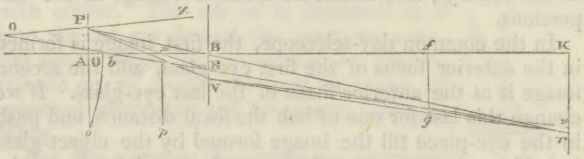
These eye-pieces will admit the use of a micrometer at the place of the first image, because it has no distortion.

Mr Dollond was anxious to combine this achromatism of the eye-pieces with the advantages which he had found in the eye-pieces with five glasses. The eye-piece of three glasses necessarily has a very great refraction at the glass B, where the pencil which has come from the other side of the axis must be rendered again convergent, or at least parallel to it. This occasions considerable aberrations, which may be avoided by giving part of this refraction to a glass put between the first and second, in the same way as was done by the glass B put between A and C in his five-glass eye-piece. But this deranges the whole process. His ingenuity, however, surmounted the difficulty, and he made eye-pieces of four glasses, which seem as perfect as can be desired. He did not publish his ingenious investigation; we imagine therefore that it will be an acceptable thing to the artists to have precise instructions how to proceed.

It is evident, that if we make the rays of different colours unite on the surface of the last eye-glass but one, commonly called the *field-glass*, the thing will be done, because the dispersion from this point of union will then unite with the dispersion produced by this glass alone; and this increased dispersion may be corrected by the last eye-glass in the way already shown.

Therefore let A, B (fig. 26) be the stations which we have fixed on for the first and second eye-glasses, in order to give a proper portion of the whole refraction to the second glass. Let b be the anterior focus of B. Draw P Br through the centre of B. Make Ab : bB = AB : BK. Draw the perpendicular Kr, meeting the refracted ray in r. We know by the focal theorem, that red rays diverging from P will converge to r; but the violet ray PV, being more refracted, will cross Rr in some point g. Drawing the perpendicular fg, we get f for the proper place of the field-glass. Let the refracted ray Rr, produced backward, meet the ray OP coming from the centre of the object-glass in O. Let the angle of dispersion RPV be called p, and the angle of dispersion at V, that is, rVv, be v, and the angle VrR be r.

Fig. 26.



It is evident that OR : OP = $p : v$, because the dispersions are proportional to the sines of the refractions, which in this case are very nearly as the refractions themselves.

Let $\frac{\mathrm{OP}}{\mathrm{OR}}\left(\text{or } \frac{op}{p\mathrm{B}} \text{ or } \frac{p\mathrm{B}}{b\mathrm{B}}\right)$ be made $= m$. Then $v = mp$; also $p : r = \mathrm{BK} : \mathrm{AB} = b\mathrm{B} : \mathrm{A}b$, and $r = p\,\frac{\mathrm{A}b}{b\mathrm{B}}$, or making $\frac{\mathrm{A}b}{\mathrm{B}b} = n$, $r = np$; therefore $v : r = m : n = \frac{p\mathrm{B}}{b\mathrm{B}} : \frac{\mathrm{A}b}{b\mathrm{B}}$ $= p\mathrm{B} : \mathrm{A}b$.

The angle $\mathrm{R}g\mathrm{V} = g\mathrm{V}r + gr\mathrm{V} = p\,(m+n)$; and $\mathrm{R}g\mathrm{V} : \mathrm{R}rv = \mathrm{R}r : \mathrm{R}g$, or $m + n : n = \mathrm{R}r : \mathrm{R}g$, and $\mathrm{R}g = \mathrm{R}r\,\frac{n}{m+n}$. But R$r$ is ultimately $= \mathrm{BK} = \mathrm{AB}\,\frac{b\mathrm{B}}{\mathrm{A}b} = \frac{\mathrm{AB}}{n}$, therefore $\mathrm{R}g = \frac{\mathrm{AB}}{n} \cdot \frac{n}{m+n} = \frac{n}{m+n}$, and $\mathrm{B}f = \frac{\mathrm{AB}}{m+n}$.

This value of Bf is evidently $= b\mathrm{B} \cdot \frac{\mathrm{AB}}{p\mathrm{B} + \mathrm{A}b}$. Now bB being a constant quantity while the glass B is the same, the place of union varies with $\frac{\mathrm{AB}}{p\mathrm{B} + \mathrm{A}b}$. If we remove B a little farther from A, we increase AB, and pB, and Ab, each by the same quantity. This evidently diminishes Bf. On the other hand, bringing B nearer to A increases Bf. If we keep the distance between the glasses the same, but increase the focal distance bB, we augment Bf, because this change augments the numerator and diminishes the denominator of the fraction $\frac{b\mathrm{B} \cdot \mathrm{AB}}{p\mathrm{B} + \mathrm{A}b}$.

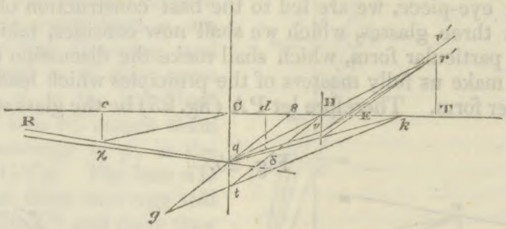
In this manner we can unite the colours at what distance we please, and consequently can unite them in the place of the intended field-glass, from which they will diverge with an increased dispersion, viz. with the dispersion competent to the refraction produced there, and the dispersion $p\,(m+n)$ conjoined.

It only remains to determine the proper focal distances of the field-glass and eye-glass, and the place of the eye-glass, so that this dispersion may be finally corrected.

This is an indeterminate problem, admitting of an infinity of solutions. We shall limit it by an equal division of the two remaining refractions, which are necessary in order to produce the intended magnifying power. This construction has the advantage of diminishing the aberration. Thus we know the two refractions, and the dispersion competent to each; it being nearly $\frac{1}{27}$th of the refraction. Call this q. The whole dispersion at the field-glass consists of q, and of the angle KgV of fig. 19, which we also know to be $= p\,(m+n)$. Call their sum s.

Let fig. 27 represent this addition to the eye-piece. Cg is the field-glass coming in the place of fg of fig. 26, and Rgw is the red ray coming from the glass BR. Draw gs parallel to the intended emergent pencil from the eye-glass; that is, making the angle Csg with the axis correspond to the intended magnifying power. Bisect this angle by the line gK. Make $sg : gq = s : q$, and draw qK, cutting Cg in t. Draw $t\delta$D, cutting gk in δ, and the axis in D. Draw δd and Dr perpendicular to the axis. Then a lens placed in D, having the focal distance Dd, will destroy the dispersion at the lens gc, which refracts the ray gw into gr.

Fig. 27.

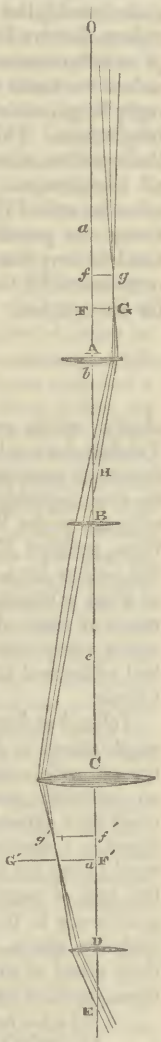


Let gv be the violet ray, making the angle $vgr = s$. It is plain, by the common optical theorem, that gr will be refracted into rr' parallel to δD. Draw gDr' meeting rr', and join vr'. By the focal theorem, two red rays gr, gv will be united in r'. But the violet ray gv will be more refracted, and will take the path vv', making the angle of dispersion $r'vv = q$ very nearly, because the dispersion at v does not sensibly differ from that at r. Now, in the small angles of refraction which obtain in optical instruments, the angles $rr'v$, rgv are very nearly as gr and rr', or as gD and Dr', or as CD and DT; which, by the focal theorem, are as Cd and dD; that is, Dd : dc = $rgv : rr'v$. But Dd : dC = Dδ : δt = $sg : gq = s : q$. But $rgv = s$; therefore $rr'v = q = r'vv'$, and vv' is parallel to rr', and the whole dispersion at g is corrected by the lens Dr. The focal distance Cc of Cg is had by drawing Cϰ parallel to Kg, meeting Rg in ϰ, and drawing ϰc perpendicular to the axis.

It is easy to see that this (not inelegant) construction is not limited to the equality of the refractions *wgr*, *Krr'*. In whatever proportion the whole refraction *wgs* is divided, we always can tell the proportion of the dispersions which the two refractions occasion at *g* and *r*, and can therefore find the values of *s* and *q*. Indeed this solution includes the problem in p. 167, col. 2, par. 2; but it had not occurred to us till the present occasion. Our readers will not be displeased with this variety of resource.

The intelligent reader will see that in this solution some quantities and ratios are assumed as equal which are not strictly so, in the same manner as in all the elementary optical theorems. The parallelism, however, of *vv'* and *rr'* may be made accurate by pushing the lens D*r* nearer to C*g*, or retiring it from it. We may also, by pushing it still nearer, induce a small divergency of the violet ray, so as to produce accurate vision in the eye, and may thus make the vision through a telescope more perfect than with the naked eye, where dispersion is by no means avoided. It would therefore be an improvement to have the eye-glass in a sliding tube for adjustment. Bring the telescope to distinct vision; and if any colour be visible about the edges of the field, shift the eye-glass till this colour is removed. The vision may now become indistinct; but this is corrected by shifting the place of the whole eye-piece.

Fig. 28.



We have examined trigonometrically the progress of a red and a violet ray through many eye-pieces of Dollond's and Ramsden's best telescopes, and we have found in all of them that the colours are united on or very near the field-glass; so that we presume that a theory somewhat analogous to ours has directed the ingenious inventors. We meet with many made by other artists, and even some of theirs, where a considerable degree of colour remains, sometimes in the natural order, and often in the contrary order. This must happen in the hands of mere imitators, ignorant of principle. We presume that we have now made this principle sufficiently plain.

Fig. 28 represents the eye-piece of a very fine spy-glass by Mr Ramsden; the focal length of its object-glass is $8\frac{1}{2}$ inches, with $1\frac{1}{10}$th of aperture, 2° 05' of visible field, and 15·4 magnifying power. The distances and focal lengths are of their proper dimensions, but the apertures are $\frac{1}{2}$ larger, that the progress of a lateral pencil might be more distinctly drawn. The dimensions are as follow:

Foc. lengths A$a = 0{\cdot}775$, B$b = 1{\cdot}025$, C$c = 1{\cdot}01$, D$d = 0{\cdot}79$.
Distances AB $= 1{\cdot}18$, BC $= 1{\cdot}83$, CD $= 1{\cdot}105$.

It is perfectly achromatic, and the colours are united, not precisely at the lens C*g*, but about $\frac{1}{20}$th of an inch nearer the eye-glass.

It is obvious that this combination of glasses may be used as a microscope; for if, instead of the image formed by the object-glass at FG, we substitute a small object, illuminated from behind, as in compound microscopes, and if we draw the eye-piece a very small way from this object, the pencils of parallel rays emergent from the eye-glass D will become convergent to very distant points, and will there form an inverted and enlarged picture of the object, which may be viewed by a Huyghenian eye-piece; and we may thus get high magnifying powers without using very deep glasses. We tried the eye-piece of which we have given the dimensions in this way, and found that it might be made to magnify 180 times with very great distinctness. When used as the magnifier of a solar microscope, it infinitely surpasses every thing we have ever seen. The picture formed by a solar microscope is generally so indistinct, that it is fit only for amusing ladies; but with this magnifier it seemed perfectly sharp. We therefore recommend this to the artists as a valuable article of their trade.

The only thing which remains to be considered in the theory of refracting telescopes, is the forms of the different lenses. Hitherto we have had no occasion to consider any thing but their focal distances; but their aberrations depend greatly on the adjustment of their forms to their situations. When the conjugate focuses of a lens are determined by the services which it is to perform, there is a certain form or proportion between the curvatures of their anterior and posterior surfaces, which will make their aberrations the smallest possible.

It is evident that this proportion is to be obtained by making the fluxion of the quantity within the parenthesis in the formula at the top of col. 2, p. 151, equal to nothing. When this is done, we obtain this formula for *a*, the radius of curvature for the anterior surface of a lens; $\frac{1}{a} = \frac{2m^2+m}{2m+4} + \frac{4m+4}{2(m+4)r}$, where *m* is the ratio of the sine of incidence to the sine of refraction, and *r* is the distance of the focus of incident rays, positive or negative, according as they converge or diverge, all measured on a scale of which the unit is *n*, = half of the radius of the equivalent isosceles lens.

It will be sufficiently exact for our purpose to suppose $m = \frac{3}{2}$, though it is more nearly $\frac{31}{20}$. In this case, $\frac{1}{a} = \frac{6}{7} + \frac{10}{7r} = \frac{6r+10}{7r}$. Therefore $a = \frac{7r}{6r+10}$, and $\frac{1}{b} = \frac{1}{a} - 1 = \frac{1-a}{a}$.

As an example, let it be required to give the radii of curvature in inches for the eye-glass *be* of page 164, col. 1, par. 2, which we shall suppose of $1\frac{1}{2}$ inch focal distance, and that *ec* ($= r$) is $3\frac{3}{4}$th inches.

The radius of curvature for the equivalent isosceles lens is 1·5, and its half is 0·75. Therefore $r = \frac{3\frac{1}{4}}{0{\cdot}75} = 5$; and our formula is $a = \frac{7 \times 5}{6 \times 5 + 10} = \frac{35}{40} = 0{\cdot}875$; and $\frac{1}{b} = \frac{1-a}{a} = \frac{0{\cdot}125}{0{\cdot}875}$, and $b = \frac{0{\cdot}875}{0{\cdot}125} = 7$.

These values are parts of a scale of which the unit is 0·75 inch. Therefore

a, in inches, $= 0{\cdot}875 \times 0{\cdot}75 = 0{\cdot}65525$,
b, in inches, $= 7 \times 0{\cdot}75 = 5{\cdot}25$.

And here we must observe that the posterior surface is concave; for *b* is a positive quantity, because $1 - a$ is a positive quantity as well as *a*; therefore the centre of sphericity of both surfaces lies beyond the lens.

And this determination is not very different from the usual practice, which commonly makes this lens a plane convex with its flat side next the eye: and there will not be much difference in the performance of these two lenses; for in all cases of maxima and minima, even a pretty considerable change of the best dimensions does not make a sensible change in the result.

The same consideration leads to a rule which is very simple, and sufficiently exact for ordinary situations. This is to make the curvatures such, that the incident and emergent pencils may be nearly equally inclined to the surfaces of the lens. Thus in the eye-piece with five glasses, A and B should be most convex on their anterior sides; C should be most convex on the posterior side; D should be nearly isosceles; and E nearly plano-convex.

But this is not so easy a matter as appears at first sight. The lenses of an eye-piece have not only to bend the several pencils of light to and from the axis of the telescope; they have also to form images on the axes of these pencils. These offices frequently require opposite forms, as mentioned in par. 3, col. 2, p. 162. Thus the glass A, fig. 28, should be most convex on the side next the object, that it may produce little distortion of the pencils. But it should be most convex next the eye, that it may produce distinct vision of the image FG, which is very near it. This image should have its concavity turned towards A, whereas it is towards the object-glass. We must therefore endeavour to make the vertical image *fg* flatter, or even convex. This requires a glass very flat before and convex behind. For similar reasons the object-glass of a microscope and the simple eye-glass of an astronomical telescope should be formed in the same way.

This is a subject of most difficult discussion, and requires a theory for which our limits do not afford room. The artists are obliged to grope their way. The proper method of experiment would be, to make eye-pieces of large dimensions, with extravagant apertures to increase the aberrations, and to provide for each station A, B, C, and D, a number of lenses of the same focal distance, but of different forms; and we would advise making the trial in the way of a solar microscope, and to have two eye-pieces on trial at once. Their pictures can be formed on the same screen, and accurately compared; whereas it is difficult to keep in remembrance the performance of one eye-piece, and compare it with another.

We cannot add any thing to what Dr Smith has delivered on the theory of reflecting telescopes. There appears to be the same possibility of correcting the aberration of the great speculum by the contrary aberration of a convex small speculum, that we have practised in the compound object-glass of an achromatic refracting telescope. But this cannot be, unless we make the radius of the convex speculum exceedingly large, which destroys the magnifying power and the brightness. This therefore must be given up. Indeed their performance, when well executed, does already surpass all imagination. Dr Herschel found great advantages in what he called the *front view*, not using a plane mirror to throw the pencils to one side. But this cannot be practised in any but telescopes so large that the loss of light occasioned by the interposition of the observer's head may be disregarded. (B. B. B.)

TELETZKOI, a lake of Siberia, in the government of Kolivan, extending about fifty-two miles from north to south, and ten from east to west. It is supplied by a river which rises in Chinese Tartary, and is bordered by a lofty chain of mountains connected with the Altai.

TELFORD, Thomas, a very able and distinguished engineer, was born in the parish of Westerkirk and county of Dumfries, on the 9th of August 1757. His father, who followed the occupation of a shepherd, died before the close of that year; and the orphan boy was thus left to the sole care of his mother, whose maiden name was Janet Jackson. She survived till the year 1794, and had the high satisfaction of seeing him already entered upon a very prosperous career. In his correspondence with her, he is said to have written all his letters in printed characters, that she might be able to read them without assistance. His very limited education he received at Westerkirk school; and, during the summer season, was employed by his uncle as a shepherd boy. This occupation left him abundant leisure for reading; and his early and eager love of knowledge he was enabled to gratify by the kindness of some individuals, who accommodated him with the loan of books. At an early age, he quitted Westerkirk school and the care of his uncle's flock, in order to learn the trade of a mason in the neighbouring town of Langholm. After the completion of his apprenticeship, he continued for some time to work as a journeyman. Langholm bridge, over the river Esk, was partly reared by hands which were destined for more scientific occupations.

At this early period of his life, he was remarkable for his elastic spirits and gay humour. In his native district of Eskdale, he was long remembered as "laughing Tom." His favourite pursuits were not yet scientific, but literary, and he even aspired at the reputation of a poet. He was a contributor to the Weekly Magazine; and one of his compositions, entitled *Eskdale, a Poem*, appeared with the name of the author in a provincial miscellany.[1] It is an imitation of Pope's Windsor Forest, and at least displays some command of poetical language and imagery. He subsequently wrote many verses; and from a poetical epistle which he had addressed to Burns, some extracts were printed by Dr Currie.

Telford at length quitted Eskdale, and sought for better employment in Edinburgh, where he is said to have continued, with unremitting application, to study architecture on scientific principles. In the mean time, however, he must have earned his daily bread by the labour of his hands. Here he remained till the year 1782, when he was emboldened to try his fortune in London. He had now reached the age of twenty-five, and seems to have acquired new confidence in the resources of his own talents. In his descriptive poem, two Eskdale families have each received their mead of praise; and to two individuals belonging to those families he owed many obligations.

> Who has not heard of Johnstone's sounding name,
> Or Pasley's, shining in the rolls of fame?

Mr John Pasley, a wealthy merchant, was the brother of Sir Thomas Pasley, and the uncle of Sir John Malcolm. He was remarkable, even in a proverbial degree, for his anxious attention to the welfare of the Eskdale youth who repaired to the metropolis.[1] This ingenious young man, then a journeyman mason, he received with his habitual kindness, and not only treated him with hospitality, but, we have every reason to believe, rendered him very important services, and greatly contributed to his subsequent advancement. In his account of his own life, it is observable that Telford makes not the slightest allusion to his benefactor. As to his occupation, he states that he was fortunate in being employed at the quadrangle of Somerset-place, where he acquired much practical information, both in the useful and ornamental branches of architecture. After a residence of two years in London, he was engaged in superintending the building of a house in the dock-yard at Portsmouth, intended for the resident commissioner. For this appointment we suppose him to have been indebted to the influence of Mr Pasley, exercised through his brother the admiral. "During the three years," he remarks, "that I attended the building of the commissioner's house, and of a new chapel for the dock-yard, I had an opportunity of observing the various operations necessary in the foundations and construction of graving docks, wharf-walls, and similar works, which afterwards became my chief occupation."

---

[1] The Poetical Museum; containing Songs and Poems on almost every subject, mostly from periodical Publications. Hawick, 1784, 12mo. *Eskdale* occurs at p. 267, where it is introduced with this notice of the author: "Thomas Telford, author of the following Poem, was bred a mason at the village of Langholm, on the banks of the Esk; a young man of no education but common reading, assisted by some few books lent him by the neighbouring gentlemen." Langholm, it is to be remarked, is not a village, but a market-town, containing about 2000 inhabitants. An improved edition of the poem was printed at Shrewsbury. It is inserted in the appendix to the Life of Telford, p. 655. An "Epistle to Mr Walter Ruddiman," signed *Eskdale Tam*, and dated at Langholm, is subjoined to "Two Scots Poems; the Silver Gun, in three cantos, and Hallow-E'en. By John Main." Glasgow, 1783, 4to. This epistle, which is commendatory of the Dumfries poet, was first printed in the year 1779 in the Weekly Magazine, vol, xliv. p. 151. Telford acknowledged himself to be the author. In the last edition of the principal poem, he is mentioned with commendation as a poet as well as engineer. See Mayne's Siller Gun, p. 78, 227. Lond. 1836, 16to.

Having terminated his engagement at Portsmouth in 1787, he was employed by Sir William Pulteney to superintend some alterations in Shrewsbury Castle, which he wished to fit up as a temporary residence. This baronet likewise belonged to Westerkirk, being a younger son of Sir James Johnstone of Westerhall. For several years he practised at the Scotish bar, but by his marriage with Frances Pulteney, niece to the earl of Bath, he acquired a princely fortune; and being a man of penurious habits, he continued till the end of his life to accumulate riches, which his only child, created countess of Bath, was miserably incapable of enjoying. It is more than probable that Telford had been recommended to him by Mr Pasley; and to this new connexion he was indebted for a very favourable opening of his career as a civil engineer. He was appointed surveyor of the public works in the rich and extensive county of Salop; and this office he retained till the time of his death. His chief attention was thus devoted to building and repairing bridges; but, as an architect, he was likewise employed in superintending the erection of churches and other edifices. His politics did not coincide with those of his patron. "Telford in his youth," says Mr Rickman, "is known to have been tinctured with the then fashionable doctrines of democracy, while the strong mind of his patron derided and detested the flimsy tissue, as might be expected from his penetration and experience. A dangerous rupture was once likely to ensue, when Telford rather improperly transmitted some of the political trash of the day under his patron's frank;[2] but the latter pardoned him, after due animadversion."

Telford's progress in his professional career, though not uncommonly rapid, was steady and certain; and every new opportunity of exerting his talents contributed to extend a reputation which at length became unrivalled. In 1790 he was employed by the British Fishery Society to inspect the harbours at their several stations, and to devise a plan for an extensive establishment in the county of Caithness; and after an interval of three years he was intrusted with the management of the Ellesmere Canal. In 1803 the parliamentary commissioners for making roads and building bridges in the Highlands, as well as the commissioners for the Caledonian Canal, appointed him their engineer. Under the former board, eleven hundred and seventeen bridges were erected, and nine hundred and twenty miles of new roads were made; and under the latter board was completed the Caledonian Canal, a work of great labour and expense. Under the road commissioners on the Carlisle, Glasgow, and Lanarkshire roads, thirty bridges were erected; one of them having a span of a hundred and fifty feet, and another being a hundred and twenty-two feet high. In both parts of the kingdom, he afterwards conducted a great variety of public operations; and in 1808 he was employed by the Swedish government to execute a regular survey, and lay down correct plans and sections of the country between Lake Wenern and the shore of the Baltic, near Soderkoping, and to make a detailed Report on the subject, with the view of connecting the great fresh-water lakes, and forming a direct communication between the North Sea and the Baltic. Having completed this service, he embarked at Gottenburg early in October. In August 1813 he again visited Sweden, and inspected all the works then commenced, which chiefly consisted of excavations. The king bestowed upon him a Swedish order of knighthood, but his good sense prevented him from assuming the title. In our days, such honours "be good cheap." As a further mark of the royal approbation, he received the king's portrait set in valuable diamonds.

He continued for many years to be engaged in a great variety of similar undertakings, indeed in all the most important undertakings that were then in progress; and a simple enumeration of his roads, bridges, canals, and harbours, would itself occupy a very considerable space. "It has been said, and no doubt truly, that Mr Telford was inclined to set a higher value on the success which attended his exertions for improving the great communication from London to Holyhead, the alterations of the line of road, its smoothness, and the excellence of the bridges, than on that of any other work he executed. The Menai Bridge will unquestionably be the most imperishable monument of Mr Telford's fame. This bridge over the Bangor ferry, connecting the counties of Carnarvon and Anglesea, partly of stone and partly of iron, on the suspension principle, consists of seven stone arches, exceeding in magnitude every work of the kind in the world."[3]

Telford was possessed of a robust frame, and till he reached the age of seventy, he had never been visited with any serious illness. While at Cambridge in the year 1827, he was afflicted with a severe and dangerous disorder; and although he gradually recovered a certain degree of health, he never recovered his former vigour. He became subject to bilious derangements in an alarming degree; and these recurring in the spring and autumn of 1832 and 1833, and again in the spring of the ensuing year, greatly impaired his strength. On the 23d of August 1834 he experienced an attack, which, after affording some delusive expectations of his recovery, reached its fatal termination on the second of September, after he had completed the seventy-seventh year of his age. He died at his house in Abingdon Street, Westminster, and his remains were deposited in the Abbey.

---

[1] The son of an unprosperous farmer had been recommended to him by his kind-hearted relations at Burnfoot; and as the young man had not been trained to business of any kind, he thought the best way of serving him was to procure him a clerkship in a man of war. He accordingly lost no time in writing to his brother Admiral Pasley; but the admiral informed him that he had no employment for any such person. The application was immediately renewed. An answer was returned, that he really had no employment for the young man, and could not make employment for him. Even this answer was not received as final. One letter followed another so rapidly, that at length the admiral wrote to this effect: "For God's sake, send me S. L., and let me see if any thing can be done for him." This young man speedily became a purser; and at the termination of the first French war, retired from the service in very prosperous circumstances.

[2] It was most probably addressed to his intimate friend Andrew Little, who kept a private and very small school at Langholm, and who completely agreed with him in his political creed. Telford did not neglect to send him a copy of Paine's *Rights of Man*; and as he was totally blind, he employed one of his scholars to read it in the evenings. Mr Little had received an academical education before he lost his sight; and, aided by a memory of uncommon powers, he taught the classics, and particularly the Greek classics, with much higher reputation than any other schoolmaster within a pretty extensive circuit. Two of his pupils read all the Iliad, and all or the greater part of Sophocles. After hearing a long sentence of Greek or Latin distinctly recited, he could generally construe and translate it with little or no hesitation. He was always much gratified by Telford's visits, which were not infrequent, to his native district.

[3] Annual Biography and Obituary, vol. xix. p. 208.

He bequeathed legacies to the amount of L.16,600, but his own relations were entirely overlooked. "After his mother's death," we are instructed, "Telford had few family connections to provide for; and although he was ready to help these, when occasionally in want of pecuniary assistance, yet he did not divide his property amongst them, having from experience formed a strong opinion against the removal of any man from his station in life." Telford's original station was that of a journeyman mason at Langholm; and was it for him to appeal to his own experience, and to form a strong opinion against the removal of any man from his station in life? He had a cousin named James Jackson, whose labours as a mason had rounded his ample shoulders almost to deformity; and being no longer fit for hard work, he endeavoured to earn a livelihood by teaching a very humble school in Westerkirk. If he received any pecuniary assistance from his more fortunate relation, it must to all appearance have come in very scanty portions. The moral philosophy of this engineer and his editor is by no means suited to our unrefined taste. To Colonel Pasley, the nephew of his early benefactor, he bequeathed a legacy of five hundred pounds. We likewise mention to his credit that he bequeathed a thousand pounds to the subscription library of Westerkirk, and the same amount to that of Langholm. In the last days of a lengthened life, he had not utterly forgotten

> Thy pleasant banks, O Esk, and verdant groves,
> The seat of innocence, and purest loves.

The defects of his early education he had endeavoured to remedy by his own unaided exertions in his mature years. We are informed that he had taught himself Latin, French, and German, and could read those languages with facility, and converse freely in French. He is likewise said to have been well acquainted with algebra, but to have placed more reliance on experiment than on mathematical investigation. A combination of science with experiment he doubtless understood and practised, as the best method of proceeding in his more difficult undertakings. He was a lover of literature, and was fond of miscellaneous reading. His relish for poetry never deserted him; and two poets, Campbell and Southey, were remembered in his will. To the Edinburgh Encyclopædia he contributed the articles Architecture, Bridge-building, and Canal-making. His account of his own life is however the most lasting monument of his professional talents. Of his personal history, the details are very meagre and unsatisfactory; but the record of his proceedings, and the result of his experience, as an engineer who had been engaged in such important and multifarious operations, constitute it a work of great interest in its own department.[1] (x.)

TELINGANA, an ancient kingdom of Hindustan, intersected by the river Godavery. It is now possessed by the British and the nizam.

TELL, William, an illustrious Swiss patriot, chief instrument of the revolution which delivered the Swiss cantons from the German yoke in 1307. Grisler, the governor of these provinces for the emperor Albert, having ordered him, under pain of death, to shoot at an apple placed on the head of one of his children, he had the dexterity, though the distance was very considerable, to strike it off without hitting the child. The tyrant, perceiving he had another arrow concealed under his cloak, asked him for what purpose? To which he boldly replied, "To have shot you through the heart, if I had had the misfortune to kill my son." The enraged governor now ordered him to be hanged; but his fellow-citizens, animated by his fortitude and patriotism, flew to arms, attacked and vanquished Grisler, who was shot to death by Tell; and the association for the independency took place that instant.

TELLER, an officer of the exchequer, in ancient records called *tallier*. There were four of these officers, whose duty it was to receive all sums due to the king, and to give the clerk of the pells a bill to charge him therewith. They likewise paid all money due from the king, by warrant from the auditor of the receipt; and made weekly and yearly books both of their receipts and payments, which they delivered to the lord-treasurer.

TELLICHERRY, a seaport in the south of India, on the coast of Malabar, and long the chief settlement of the English. But the East India Company's commerce having in 1800 been transferred to Mahe, it has since declined, though it is still inhabited by a number of rich merchants, and is a principal mart for sandal-wood and cardamums. The inhabitants are more civilized than in the adjoining districts. Ships of considerable burden may anchor opposite the town in six fathoms water. Long. 75. 36. E. Lat. 11. 44. N.

TELLO, a town of Celebes, and formerly the capital of an independent principality. Long. 119. 30. E. Lat. 5. 5. S.

TEMBLEQUE, a town of Spain, in the province of Toledo and the partido of Alcazar de St Juan. It stands in a pleasant and beautiful part of the province; and here large markets are held, especially for sheep, of which vast numbers are sold. It contains 900 houses, with 4400 inhabitants. There is a large establishment for refining saltpetre, which is found in the vicinity. Long. 3. 37. 4. W. Lat. 39. 41. 5. N.

TEMESWAR, an extensive palatinate in the Austrian kingdom of Hungary. It is bounded on the north by Arad, on the east by Krassova, on the south by the Turkish dominions, and on the west by Torontal. It extends over 2254 square miles, and comprises one city, six market-towns, and 180 villages, besides hamlets, containing 43,270 houses, with 268,400 inhabitants, the majority of whom are Greeks, Walachians, or Servians, but having among them several German and Maygaren colonists of their several religious and languages. One half of the cultivated land is devoted to the growth of corn, about one fortieth part is planted with vines, and the rest is allotted to pastures and wood. The country is generally level, and is well watered by the streams of the Maros, the Temes, and the Vega. The climate is hot, moist, and not very healthy. The soil is fertile, producing, when well cultivated, abundant crops of wheat, maize, and rice. The produce also of hemp, flax, tobacco, and safron, is copious, and occasions a considerable trade to other districts. Wine is very good in some parts, in others but indifferent. Both red and white wines are made. The rivers are well stored with fish of all kinds, and the fields abound in game. The whole trade centres in the capital city, of the same name as the palatinate. This country belonged to the Turks till the year 1716, when it was a mere military occupation of the Austrians, and was overrun with wild people from the surrounding countries. In 1772 a civil government was formed, since which it has gradually become orderly, and the condition of society has much improved. Under the old name it formed a part of the Bannat, which was divided in 1779 into three sections, Torontal, Temeswar, and Krassova.

---

[1] Life of Thomas Telford, Civil Engineer, written by himself; containing a descriptive Narrative of his Professional Labours: with a folio Atlas of Copper Plates. Edited by John Rickman, one of his Executors; with a preface, supplement, annotations, and index. Lond. 1833, 4to.

Temeswar, a city of the kingdom of Hungary, in the province of the Farther Theiss, and in the county of its own name, of which it is the capital. It stands near the river Vega, to which a canal leads. It is one of the best built places of the kingdom, and is most strongly fortified, as one of the chief barriers towards Turkey. It is the seat of the staff of the military colonies, and the see of a bishop both of the Catholic and of the Greek church. The former has a fine Gothic cathedral, and the latter an elegant modern building. It is a place of considerable trade, making oil, tobacco, paper, iron wares, with silk and woollen cloths. Wine and silk are raised in the neighbourhood. It contains 1360 houses, with 12,600 inhabitants, of various nations and languages. Long. 21. 35. 7. E. Lat. 45. 22. 27. N.

TEMPE, a spot in Greece, of great celebrity for its beauty among the ancient Greeks. It is a valley about seven miles long, and varying in breadth from 100 to 2000 feet, being the passage between the mountains of Ossa and Olympus, leading from Thessaly to Macedonia. According to tradition, this opening was made by an earthquake. The river Peneus flows through it on its way to Salonica, where it empties its waters into the sea. A modern visitor says, "the scenery of this valley fully gratified our expectations. In some places it is sylvan, calm, and harmonious, and the sound of the waters of the Peneus accords with the grace of the surrounding landscape; in others it is savage, terrific, and abrupt, and the river roars with violence, darkened by the frown of stupendous precipices."

TEMPERAMENT, among physicians, the same with constitution, or a certain disposition of the solids and fluids of the human body, by which it may be properly denominated strong, weak, lax, &c.

In every person there are appearances of a temperament peculiar to himself, though the ancients only took notice of four, and some have imagined these were deduced from the theories of the four humours or four cardinal qualities; but it is more probable that they were first founded on observation, and afterwards adapted to those theories, since we find that they have a real existence, and are capable of receiving an explanation. The two that are most distinctly marked are the sanguineous and melancholic, viz. the temperaments of youth and age.

1. *Sanguineous.* This is accompanied by laxity of solids, discoverable by the softness of hair, and succulency; large system of arteries, redundancy of fluids, florid complexion; sensibility of the nervous power, especially to pleasing objects; irritability from the plethora; mobility and levity from lax solids. These characters are distinctly marked, and are proved by the diseases incident to this age, as hæmorrhages, fevers, &c.; but these, as they proceed from a lax system, are more easily cured.

2. *Melancholic Habit.* Here greater rigidity of solids occurs, discoverable by the hardness and crispature of the hair; small proportion of the fluids, hence dryness and leanness; small arteries, hence pale colour; venous plethora, hence turgescency of these, and lividity; sensibility, frequently exquisite; moderate irritability, with remarkable tenacity of impressions; steadiness in action and slowness of motion, with great strength; for excess of this constitution in maniacs gives the most extraordinary instance of human strength we know. This temperament is most distinctly marked in old age and in males. The sanguineous temperament of youth prevents us from distinguishing the melancholic till the decline of life, when it is very evident, from diseases of the veins, hæmorrhoids, apoplexy, cachexy, obstructions of the viscera, particularly of the liver, dropsies, affections of the alimentary canal, chiefly from weaker influence of the nervous power. So much for the sanguineous and melancholic temperaments; the other two are not so easily explained. The choleric temperament takes place between youth and manhood. In the

3. *Choleric*, the distribution of the fluids is more exactly balanced; there is less sensibility, and less obesity, with more irritability, proceeding from greater tension, less mobility and levity, and more steadiness in the strength of the nervous power.

4. *Phlegmatic.* This temperament cannot be distinguished by any characters of age or sex. It agrees with the sanguineous in laxity and succulency. It differs from that temperament and the melancholic, by the more exact distribution of the fluids. Again, it differs from the sanguineous, by having less sensibility, irritability, mobility, and perhaps strength, though sometimes indeed this last is found to be great.

These are the ancient temperaments. The temperaments, indeed, are much more various, and very far from being easily marked and reduced to their genera and species, from the great variety which is observable in the constitutions of different men.

Temperament *of the Musical Scale.* "In the modern system, called *tempered*," says a German writer on music, "all the intervals are not employed in their original perfection, as the nature of the harmonic scale presents them, but lose, sometimes in this interval, sometimes in that other, something of their acuteness or gravity. In fact, experience shows that, in tuning the major and minor thirds, the fifths, and the fourths, in their original perfection, when we reach a certain term, we meet with a fault of too great excess or too great deficiency; and from this faultiness arises the necessity of tempering this or that sound, in order to combine reciprocally the intervals of one mode with those of another, the result of which is called *temperament.*" The nature and the principle of temperament, as applied to musical instruments of fixed sounds, may be understood by perusing pp. 610, 611, of vol. xv., article Music, and p. 533 of vol. xvi., article Organ. We shall here content ourselves with giving a very few additional remarks, and with indicating some works whence further information may be derived, seeing that the subject of musical temperament is not of sufficient importance to occupy much room in a work like this. The various systems of temperament that have been proposed for such instruments as the organ, the harpsichord, the piano-forte, &c. offer only a choice in the distribution of the imperfections of false intonation. The unequal temperament is that usually adopted; but it must be observed, that tuners in general proceed more by rule of routine and an indifferent ear, than according to any scientific principle of temperament. Hence the great differences found among instruments tuned by different tuners. It is a common error to suppose that "a person who sings in tune, tempers without knowing it." Even Chladni, following the lead, has asserted this; while the truth is, that there is *no temperament* in the voice of a singer whose intonation is perfect, unless his voice and ear happen to be misguided by the accompaniment of a *tempered* instrument, that is, an instrument *out of tune.* When left to itself, the voice of such a singer, in executing the most intricate modulations, forms the sounds in their true ratios to the different tonics or key-notes that occur, and, in the wonderful subtlety of the intonations of that only perfect musical instrument, the human voice, possesses all the intonations that are necessary to form these sounds exactly. Nearly the same thing occurs in the case of such a violin-player as a Viotti or a Paganini when he plays alone, and undisturbed by the false intonations of any accompanying instrument. This was actually proved in Paris about thirty years ago, by the experiments made by M. Charles and the celebrated violinist Viotti. We may here remark, that it is of great detriment to the just intonation of a singer, to learn to sing by the guidance of an instrument such as the piano-forte, as is the common practice; for a habit of malintonation is then inevitably acquired. The same remark applies to singers taught with the accompaniment of those instruments with fretted finger-boards, such as the guitar, of which the intonation is also imperfect. As to the imperfections of the common guitar, the reader may consult the lively and ingenious work entitled Instructions to my Daughter, for playing on the Enharmonic Guitar, London, 1829. The celebrated singer Madame Mara used to say that every singer ought to learn to play the violin, in order to acquire a knowledge of just intonation. Certainly that instrument, and others of the violin kind, are the only ones we have that are capable of the nearest approach to perfect intonation, making allowances for the mechanical imperfections of their strings, as we have already hinted in the article Music. But still the human voice is the only perfect musical instrument. It has been a prevalent opinion among musicians and writers upon music, that the ancient Greeks were ignorant of many of our musical intervals, and possessed no instruments capable of executing our modern musical scales. But it is more than probable that the knowledge of the ratios of musical intervals, and of perfect intonation in a variety of scales, was much more exact among the ancient Indians, Arabians, and Greeks, than is generally supposed, or than the scanty, imperfect, and corrupted Greek relics of works on music, and the very limited examination of Indian and Arabian manuscripts, have hitherto been able to show. The reader may consult, on the subject of musical temperament, the following works. Among these, one of the best is Professor Robison's, for clearness, as well as useful suggestions. Chapter 13, *et seq*, of the third book of Salinas de Musica, Salamanca, 1577. Dr Smith's Harmonics, second edition, 1759. Dr Thomas Young's Papers in the Philosophical Transactions, and in Nicholson's Journal; also vol. ii. of his Lectures on Natural Philosophy. Cavallo's Paper in the 78th vol. of Philosoph. Trans. Vol. iv. of Professor Robison's System of Mechanical Philosophy, edited by Dr Brewster in 1822, pp. 376–451. Instructions for Playing on the Enharmonic Guitar, London, 1829. (G. F. G.)

TEMPERANCE, that virtue which a man is said to possess who moderates and restrains his sensual appetites. It is often, however, used in a much more general sense, as synonymous with moderation, and is then applied indiscriminately to all the passions.

TEMPERING, in the mechanic arts, the preparing of steel and iron, so as to render them more compact, hard, and firm, or even more soft and pliant, according to their respective occasions.

TEMPIO, a city of the island of Sardinia, the capital of the province Gallura. It stands in an Alpine district, and in a very salubrious situation. It is about twenty-five miles from the sea, is filled with antique buildings, some of the very extensive belonging to the nobility of the island. It is the seat of a bishop, whose cathedral is a large, heavy, uncompleted building, with decorations tawdry and ill executed. The city is well built, has a college, two monasteries, and a nunnery, and 5820 inhabitants. There is some industry employed in making guns and linen cloth, and some trade in preparing cheese, hams, bacon, and other salted meats.

TEMPLARS, Templers, or *Knights of the Temple*, a religious order instituted at Jerusalem in the beginning of the twelfth century, for the defence of the holy sepulchre, and the protection of Christian pilgrims. They were first called *The Poor of the Holy City*, and afterwards assumed the appellation of *Templars*, because their house was near the temple. The order was founded by Baldwin II., then king of Jerusalem, with the concurrence of the pope; and the principal articles of their rule were, that they should hear the holy office every day, or that, when their military duties should prevent this, they should supply it by a certain number of pater nosters; that they should abstain from flesh four days in the week, and on Fridays from eggs and milk-meats; that each knight might have three horses, and one esquire; and that they should neither hunt nor fowl. After the ruin of the kingdom of Jerusalem about 1186, they spread themselves through Germany and other countries of Europe, to which they were invited by the liberality of the Christians. In the year 1228, this order acquired stability by being confirmed in the council of Troyes, and subjected to a rule of discipline drawn up by St Bernard. In every nation they had a particular governor, called master of the Temple, or of the militia of the Temple. Their grand-master had his residence at Paris.

The order of Templars flourished for some time, and, by the valour of its knights, acquired immense riches, and an eminent degree of military renown; but as their prosperity increased, their vices were multiplied, and their arrogance, luxury, and cruelty rose at last to such a monstrous height, that their privileges were revoked, and their order suppressed with the most terrible circumstances of infamy and severity. Their accusers were two of their own body, and their chief prosecutor Philip the Fair of France, who addressed his complaints to Clement V. The pope, though at first unwilling to proceed against them, was under the necessity of complying with the king's desire; so that, in the year 1307, upon an appointed day, and for some time afterwards, all the knights, who were dispersed throughout Europe, were seized and imprisoned, and many of them, after trials for capital crimes, were convicted and put to death. In 1312 the whole order was suppressed by the council of Vienne. A part of the rich revenues which they possessed was bestowed upon other orders, especially on the knights of St John, and the rest confiscated to the respective treasuries of the sovereign princes in whose dominions their possessions lay. In order to justify the severity with which they were treated, the Knights Templars were charged with apostasy to the Saracens, and holding correspondence with them, with insulting the majesty of God, turning into derision the gospel of Christ, and trampling upon the obligation of all laws human and divine. Candidates, it is said, upon admission to this order, were commanded to spit, in token of contempt, upon an image of Christ, and after admission, to worship either a cat or a wooden head crowned with gold. It is further affirmed, that, among them, the odious and unnatural act of sodomy was a matter of obligation; and they are charged with other crimes too horrible to be mentioned, or even imagined. Although there may be reason to believe that in this order, as well as others of the same period, there were shocking examples of impiety and profligacy, yet it is altogether incredible that the whole order was thus enormously corrupt. The pope, indeed, though he acted with severity, acted with justice. He sent two cardinals to Paris, who, publishing his bull against the order, condemned those Templars who had made the voluntary confession to be burnt by a slow fire. The criminals recanted their former confessions, but acknowledged themselves worthy of death, because they had unjustly accused the order of crimes of which they were innocent. Several authors of those times wrote in defence of the order; and Boccaccio avers, that its extirpation was owing to the avarice of the king of France, who coveted the rich possessions which the Templars then enjoyed in that country.

The king of Aragon was much pressed to treat the Templars in his kingdom as they had been treated in France; but his constant answer was, "We must first be convinced of their guilt, and it will then be time enough to talk of their punishment." The people, however, were in general so provoked against them, that they were compelled to shut them-

T ple, Sir Wil- l m.

selves up in the fortresses belonging to their order, to prevent their being torn in pieces; and this precaution was represented to the king of Aragon as an act of rebellion. He marched with a body of troops against one of these fortresses. The knight who commanded surrendered immediately, and told the king the truth, assuring him that they desired nothing but a fair trial. With this declaration the king was extremely moved, took the whole order into his protection, and forbade any to abuse or insult them under the heaviest penalties. At the same time he declared himself ready to receive any informations against them that were supported by proofs; but he threatened the informers with punishment if they should fail to support their accusation.

These facts plead strongly for the innocence of the Templars, or at least they prove that their guilt must have been exaggerated; and many of the accusations advanced against them flatly contradict each other, and many members of this unfortunate order solemnly avowed their innocence while languishing under the severest tortures, and even with their dying breath. It therefore seems highly probable that King Philip set on foot this bloody tragedy with a view to gratify his avarice, and glut his resentment against the Templars, and especially against their grand-master, who had highly offended him. The principal cause of his invincible hatred against them was, that in his quarrel with Boniface VIII. the knights espoused the cause of the pope, and furnished him with money to carry on the war.—They originally wore a white habit, with red crosses sewed upon their cloaks as a mark of distinction.

TEMPLE, Sir William, was born in London in the year 1628. The family from which he sprung was ancient, and is said to have assumed its surname from the manor of Temple, in the hundred of Sparken Hall, in Leicestershire. He was first sent to school at Penshurst, in Kent, under the care of his uncle, the celebrated Dr Hammond, then minister of that parish; but at the age of ten he was removed to a school at Bishop-Stortford, in Hertfordshire. When he had acquired a sufficient knowledge of Greek and Latin, he returned home at the age of fifteen; and two years afterwards he went to Cambridge, where he was placed under the tuition of the learned Dr Cudworth, then fellow of Emanuel College. His father, Sir John Temple, being a statesman, seems to have designed him for the same mode of life; and on this account, after residing at Cambridge two years, which were principally spent in acquiring a competency of French and Spanish, both languages exceedingly useful for his intended pursuits, he was sent abroad to finish his education.

He began his travels by visiting France in 1648. As he chose to pass through the Isle of Wight, where his majesty was detained a prisoner, he there accidentally met with the second daughter of Sir Peter Osborne of Chicksand, in Bedfordshire, then governor of Guernsey for the king; and his lady being on a journey with her brother to St Maloes, where their father then was, the young traveller joined their party. This gave rise to an honourable attachment, which, at the end of seven years, concluded in a happy marriage. Having resided two years in France, and perfectly learned the French language, Temple made a tour through Holland, Flanders, and Germany, during which he became completely master of the Spanish. In 1654 he returned from the continent, and, marrying Miss Osborne, passed his time in retirement with his father, his two brothers, and a sister, then in Ireland, happy in that perfect harmony which has been so often remarked in their family. As he rejected all offers of employment under Cromwell, the five years which he lived in Ireland were spent chiefly in improving himself in history and philosophy; but at the restoration, in 1660, being there chosen a member of the convention, while others were trying to make their court to the king, Mr Temple opposed the poll-bill with so much spirit, that his conduct soon attracted the attention of the public, and brought him into notice. In the succeeding parliament, in 1661, he was elected with his father for the county of Carlow; and in the year following he was chosen one of the commissioners to be sent from that parliament to the king, which gave him an opportunity of waiting on the duke of Ormond, the new lord lieutenant, then at London. He soon afterwards returned to Ireland, but with a resolution of quitting that kingdom, and of removing with his family to England.

Temple, Sir William.

On his return he met with a very favourable reception from the duke of Ormond; and soon acquired such a share in his esteem, that the duke complained of him as the only man in Ireland that had never asked any thing from him. When he mentioned his design of carrying his family to England, his grace said, that he hoped he would, at least give him leave to write in his favour to the two great ministers, Clarendon, then lord chancellor, and the earl of Arlington, who was secretary of state. This the duke did in such strong terms, as procured him the friendship of these two noblemen, as well as the good opinion of the king. Temple, however, made no other use of this advantage than to tell Lord Arlington, that if his majesty had any employment abroad, which he was fit for, he should be happy to undertake it; but, at the same time, he requested that he might not be sent into any of the northern climates, to which he had a very great aversion. The secretary replied, he was very sorry he had made such an objection, as there was no other employment then undisposed of except that of going envoy to Sweden. However, in 1665, about the beginning of the first Dutch war, Arlington sent a messenger to acquaint him that he must immediately come to his house. He found that his lordship's business was to tell him, that the king had occasion to send some person abroad upon an affair of the utmost importance, and that he had resolved to make him the first offer; but that he must know, without delay, and without telling him what it was, whether he would accept of it, and that he must be ready to set out in two or three days, without mentioning it to any of his friends. After a little consideration, Temple told his lordship, that as he took him to be his friend, and as he had advised him not to refuse, as it would be an entrance into his majesty's service, he should consult no further. This business was to carry a secret commission to the bishop of Munster. He accordingly set out on the second of August, and executed it so much to the satisfaction of Charles II. that, on his return to Brussels, his majesty appointed him resident there, and created him a baronet. As Brussels was a place where he had long wished to reside, he sent for his family in April 1666; but before their arrival, he had again been obliged to depart upon business to the prelate's court. The bishop having listened to terms of accommodation with France, Sir William wrote two letters to dissuade him from that alliance; and these not having the desired effect, he went in disguise to Munster, where, though he arrived too late to secure the prince in his first engagement, yet he prevailed on him to permit five or six thousand of his best troops to enter into the Spanish service. In this journey he passed for a Spanish envoy, having twenty Spanish guards to attend him. In this manner he first went to Dusseldorp, where the duke of Neuburg, though in the French interest, gave him a guard to Dortmund; but when he reached that place, finding the gates shut, he was forced to proceed to a village at the distance of a league, which being full of Brandenburg troops, he was under the necessity of lodging in a barn, upon a straw bed, with his page for a pillow. Next day he was entertained at a castle belonging to the bishop of Munster, by one Gorges, a Scottish lieutenant-general in that prelate's service, with what he calls a very episcopal way of drinking. The general coming to the large hall, in which stood a great many flaggons ready charged, called for wine to drink the king's health. A silver bell, which might hold about two quarts, was presented to him; and, as soon as he received it, he pulled out the clapper, and giving it to Sir William, to whom he intended to drink, ordered the bell to be filled. He drank off the contents to his majesty's health; and asking Sir William for the clapper, put it on, and turning down the bell, rang it, to show that he had drunk fair, and left nothing in it. He then took out the clapper, desired Sir William to give it to whomsoever he pleased; and, ordering the bell to be filled again, presented it to Sir William: but as the latter seldom used to drink, he had generally some gentleman with him to supply his place in this respect whenever it might be necessary. Having finished his business at Munster, he returned to Brussels, where he passed a year with great pleasure and satisfaction.

Two months after the conclusion of the peace with the Dutch at Breda, Sir William's sister, who resided with him at Brussels, being very desirous of seeing Holland, he went thither incognito to gratify her desire; but while he was at the Hague, he paid a private visit to De Witt, in which he laid the foundation of that close intimacy which afterwards subsisted between them. In the spring of 1667, a new war breaking out between France and Spain, which exposed Brussels to the danger of falling into the hands of the former, Sir William sent his lady and family to England; but he himself remained there with his sister till the Christmas following, when he was ordered by the king to come over privately to London. Taking the Hague in his way, he paid another visit to De Witt, and, pursuant to his instructions, proposed those overtures to him which produced the triple alliance. Soon after his arrival at the British court, he returned, on the 16th of January 1668, with the character of envoy extraordinary and plenipotentiary to Holland; where a conference being opened, he brought that treaty to a perfect conclusion in the short space of five days. The ratifications of this alliance being exchanged on the 15th of February, he repaired to Brussels; and a treaty being set on foot between France and Spain at Aix-la-Chapelle, he proceeded for that place on the 24th of April in quality of his majesty's ambassador extraordinary and mediator. Here he arrived on the 27th; and it was chiefly owing to his assistance that the Spaniards were brought to sign the articles of that peace on the second of May. This service being completed, he returned to Brussels, with a view of remaining there in his former station of resident; but he received letters from the earl of Arlington, with the king's order to continue as ambassador, and to serve his country in that quality in Holland, as, on account of the late alliances, his majesty was resolved to renew a character which the crown of England had discontinued there since the time of King James. Sir William being now left at liberty to return to England, embraced the opportunity; and upon his arrival at London he was received with every possible demonstration of favour, both by the king and the court.

Setting out again for Holland, with his new character of the king's ambassador, he arrived at the Hague in the end of August 1668. Here he enjoyed the confidence of that great minister De Witt, and lived in great intimacy with the prince of Orange, who was then only eighteen years of age; but, in September 1669, he was hurried back to England by Lord Arlington, who ordered him to put his foot in the stirrup as soon as he should receive his letter. When Sir William waited on the earl, he found that he had not one word to say to him; for, after making him attend a long time, he only asked a few indifferent questions respecting his journey. Next day he was received as coolly by the king; but the secret soon came out, and he was urged to return to the Hague, and pave the way for a war with Holland. In this, however, he excused himself from having any concern; which so much provoked the lord-treasurer Clifford, that he refused to him an arrear of two thousand pounds due from his embassy. Disgusted with Arlington's behaviour, which was so unlike the friendship he had formerly professed, Sir William now retired to his house at Sheen, near Richmond, in Surrey; and in his retreat, when free from the hurry of business, he wrote his Observations on the United Provinces, and one part of his Miscellanies, in the time of the second Dutch war. But about the end of summer 1673, the king wishing to put an end to the war, sent for Sir William, and desired him to go to Holland to negociate a peace; but powers having been sent from thence at this time to the Marquis de Fresno, the Spanish ambassador at London, Sir William was ordered to confer with him; and a treaty was accordingly concluded in three days, and the point carried respecting the superiority of the British flag, which had been so long contested. In June 1674 he was again sent ambassador to Holland to offer the king's mediation between France and the confederates, then at war, and it was accepted not long after; Lord Berkeley, Sir William Temple, and Sir Leoline Jenkins, being declared ambassadors and mediators. Nimeguen, which Sir William had proposed, was at length agreed upon by all parties to be the place of treaty. During his stay at the Hague, the prince of Orange, who was fond of the English language, and of the plain English way of eating, constantly dined and supped once or twice a week at his house; and by this familiarity he so much gained the prince's confidence and esteem, that he had a considerable hand in his marriage with the princess Mary, daughter of James II.

In July 1676 he removed his family to Nimeguen, where he spent the remainder of that year without making any progress in the treaty; and the year following his son was sent over with letters from the lord-treasurer, ordering him to return, and succeed Mr Coventry as secretary of state. In consequence of this order, Sir William came over to England in the spring of 1677; and though the affair of the secretary's place was dropped at his desire, he did not return to Nimeguen that year. About this time, the prince having the king's leave to come over, he soon after married the princess Mary; and this gave occasion for a new coolness between Lord Arlington and Sir William, as he and the lord-treasurer Osborne, who was related to Sir William's lady, were only privy to that affair. After the prince and princess were gone to Holland, as the court always seemed inclined to favour France, the king wished to engage Sir William in some negociations with that crown; but he was so ill satisfied with this proposal, that he offered to give up all pretensions to the office of secretary; and desiring the lord-treasurer to acquaint his majesty with his intentions, retired to Sheen, in hopes of being taken at his word. Upon a discovery, however, of the French designs not to evacuate the Spanish towns agreed by the treaty to be delivered up, the king commanded him to undertake a third embassy to the states. With them he concluded a treaty, by which England engaged, in case France refused to evacuate the towns in forty days, to declare war immediately against that nation; but before half that time was elapsed, one Du Cros was sent from the English court to Holland upon a business which there damped all the good humour excited by the treaty, and which produced such sudden and astonishing changes in this country, as gave Sir William a distaste for all public employments.

In 1679 he returned to Nimeguen, where the French delayed to sign the treaty till the last hour; but having concluded it, he returned to the Hague, whence he was soon after sent for to enter upon the secretary's office, which Mr Coventry at length resolved to resign. He accordingly came over, and went to court, as all his friends hoped, with a full intention of assuming his office; but he started some difficulty, because he had not a seat in the House of Commons, thinking that, by his not being a member, the public

Temple, Sir William.

business would suffer at such a critical time, when the contests between the two parties ran so high, that the king thought fit to send the duke of York into Flanders, and the parliament to commit the lord-treasurer Danby to the Tower. After this his majesty still pressed Sir William to be secretary of state; using as an argument for his compliance, that he had nobody to consult with at a time when he had the greatest need of the best advice. Notwithstanding all this, Sir William declined the king's offer, advising him to choose a council in whom he could confide, and upon whose abilities he could depend. This advice the king followed; and the choice of the persons being concerted between his majesty and Sir William, the old council was dissolved four days after, and the new one established, of which the latter was a member.

In 1680 the councils began again to be changed, on the king's illness, at the end of summer, and the duke of York's return to court. At this juncture Sir William, endeavouring to bring to the king's favour and business some persons to whom his majesty had taken a dislike, if not an aversion, he met with such treatment from them as gave him a fresh distaste to the court, at which he seldom made his appearance; so that he resided principally at Sheen. Soon after this the king sent for him again; and having proposed that he should go as ambassador into Spain, Sir William consented; but when his equipage was almost ready, and part of the money paid down for it, the king changed his mind, and told him that he would have him defer his journey till the end of the session of parliament, in which he was chosen a member for the university of Cambridge. In this session the spirit of party ran so high that it was impossible to bring the house to any kind of temper. The duke was sent into Scotland; but this would not satisfy them, nor any thing but a bill of exclusion, which Sir William strenuously opposed, saying that "his endeavour ever should be to unite the royal family, and that he would never enter into any councils to divide them." Not long after this period, the parliament being dissolved by his majesty, without the advice of his privy council, and contrary to what he had promised, Sir William made a bold speech against that measure; for which he was very ill used by some of those friends who had been most earnest in promoting the last change in the ministry. Upon this he grew quite tired of public business, declined the offer he had of again serving for the university in the next parliament, which was soon after called, and met at Oxford; and seeing his majesty resolved to govern without his parliament, and to supply his treasury through another channel, he retired to Sheen a few days after, whence he sent word by his son, that "he would pass the rest of his days like a good subject, but would never more meddle with public affairs." From that time Sir William lived at this place till the end of that reign and for some time in the next; when, having purchased a small seat called Moor Park, near Farnham in Surrey, for which he conceived a great fondness, on account of its solitude and retirement, and its healthy and pleasant situation, and being much afflicted with the gout, and broken with age and infirmities, he resolved to spend the remainder of his life in this agreeable retreat. In his way thither he waited on King James, who was then at Windsor, and begged his favour and protection to one "that would always live as a good subject, but, whatever might happen, never again enter upon any public employment;" desiring his majesty to give no credit to any thing he might hear to the contrary. The king, who used to say that Sir William Temple's character was always to be believed, promised him whatever he desired, gently reproached him for not entering into his service, which, he said, was his own fault; and kept his word as faithfully to Sir William as Sir William did to his majesty, during the surprising turn of affairs that soon after followed by the arrival of the prince of Orange. At the time of this happy revolution, in 1688, Moor Park becoming unsafe, as it lay in the way of both armies, he retired to the house at Sheen, which he had given up to his son; to whom he refused leave, though importunately begged, to go and meet the prince of Orange at his landing; but after King James's abdication, when the prince reached Windsor, he went thither to wait upon his highness, and carried his son along with him. The prince pressed him to enter into his service, and to be secretary of state; but his age and infirmities confirming him in the resolution which he had made not to meddle any more with public affairs, he was satisfied that his son alone should enjoy his majesty's favour. Mr John Temple was upon this appointed secretary at war; but he had hardly been a week in that office, when he resolved to put an end to his own life. This resolution he carried into effect on the 14th of April 1689, by throwing himself out of a boat, hired for that purpose, in shooting London bridge; having first put stones into his pocket to make him sink speedily.

Temple.

In 1694 Sir William had the additional affliction to lose his lady, who was a very extraordinary woman, as well as an affectionate wife. He was then considerably turned of sixty; at which age he practised what he had so often declared to be his opinion, that "an old man ought then to consider himself of no farther use in the world, except to himself and his friends." After this he lived four years very much afflicted with the gout; and his strength and spirits being worn out, he expired in the month of January 1698, in the seventieth year of his age. He died at Moor Park, where his heart was buried in a silver box under the sun-dial in his garden, opposite to a window from which he used to contemplate and admire the works of nature, with his sister, the ingenious Lady Gifford. This was according to his will, in pursuance of which his body was privately interred in Westminster Abbey. There a marble monument was erected in 1722, after the death of his sister Lady Gifford. She resembled him in genius as well as in person, and left behind her the character of one of the best and most constant friends.

Sir William Temple's principal works are, 1. Memoirs from 1672 to 1691. They are very useful for those who wish to be acquainted with the affairs of that period. 2. Remarks upon the State of the United Provinces. 3. An Introduction to the History of England. 4. Letters written during his last embassies. 5. Miscellanies. He is a pleasing and popular writer; and his style was long regarded as a model of grace and elegance.

Temple, *Templum*, a public building erected in honour of some deity, either true or false; and in which the people meet for the purpose of religious worship. The word is formed from the Latin *templum*, which some derive from the Greek τέμενος, signifying the same thing. The word *templum*, in its primary sense among the old Romans, signified nothing more than a place set apart and consecrated by the augurs, whether enclosed or open, in the city or in the fields. Clemens Alexandrinus and Eusebius refer the origin of temples to the sepulchres built for the dead. This notion has been illustrated and confirmed by a variety of testimonies by Mr Farmer in his Treatise on the Worship of Human Spirits, p. 373, &c. Herodotus and Strabo represent the Egyptians as the first who built temples to the gods. The first erected in Greece is ascribed to Deucalion, by Apollonius, Argonaut. lib. iii. Some ancient people performed their sacrifices in all places indifferently, from a persuasion that the whole world is the temple of God, and that he required no other. This was the doctrine of the magi, followed by the Persians, the Scythians, the Numidians, and many other nations mentioned by Herodotus, lib. i., Strabo, lib. xv., and Cicero in his second oration against Verres. The Persians, who worshipped the sun, believed it would wrong his power to enclose him within the walls of a temple, who had the whole world for his habitation; and hence, when Xerxes ravaged Greece, the magi exhorted him to destroy all the temples he met with. The Sicyonians would build no temple to their goddess Coronis; nor the Athenians, for the like reason, erect any statue to Clemency, who, they said, was to live in the hearts of men, not within stone walls. The Bithynians had no temples but the mountains; nor had the ancient Germans any other but the woods. Even some philosophers have blamed the use and building of temples, particularly Diogenes, Zeno, and his followers the Stoics. But it may be said, that if God has no need of temples, men have need of places to meet in for the public offices of religion; and accordingly temples may be traced back even into the remotest antiquity. See Hospinian *De Origine Templorum.*

The Romans had several kinds of temples. Those built by the kings, &c. consecrated by the augurs, and in which the exercise of religion was regularly performed, were called, by way of eminence, *templa.* Those that were not consecrated were called *ædes.* The little temples that were covered or roofed they called *ædiculæ;* those open, *sacella.* Some other edifices, consecrated to particular mysteries of religion, they called *fana* and *delubra.* All these kinds of temples, Vitruvius tells us, had other particular denominations, according to the form and manner of their construction. The Romans indeed surpassed all nations with regard to temples: they not only built temples to their gods, to their virtues, to their diseases, &c., but also to their emperors, and that in their life-time. These particulars are sufficiently ascertained from medals, inscriptions, and other monuments. Horace compliments Augustus, and sets him above Hercules and all the heroes of fable; because those were only admitted into temples after their death, whereas Augustus had his temples and altars while living. Epist. ad Aug.

> Præsenti tibi maturos largimur honores,
> Jurandasque tuum per nomen ponimus aras.

Suetonius gives an instance of the modesty of that emperor, who would allow of no *temples* being erected to him in the city; and who, even in the provinces, where he knew it was usual to raise temples to the very proconsuls, refused any but those erected in the name of Rome as well as his own. The most celebrated temples among the Romans were the Capitol and Pantheon. The temple of Saturn served for the public treasury.

The temple at Jerusalem was similar in its plan to the *Tabernacle.* The first temple was begun by Solomon about the year of the world 2992, and before Christ 1012 according to some chronologers, and finished in eight years. Great mistakes have been committed respecting the dimensions of this temple, by confounding the emblematical description of Ezekiel with the plain account of it in the books of King and Chronicles. It consisted of the holy of holies, the sanctuary, and a portico. The holy of holies was a square room of twenty cubits; the sanctuary, or holy place, was forty cubits long and twenty broad, consequently the length of both these together was sixty cubits. The portico, which stood before the sanctuary, was twenty cubits long and ten cubits broad. Whether the portico was separated by a wall from the rest of the temple is not mentioned in Scripture. If it was, the whole length of the temple, computing the cubit at twenty-two inches, did not exceed 110 feet in length and thirty-six feet eight inches in breadth. In the portico stood the two brazen pillars called *Jachin* and *Boaz;* which, upon comparing and reconciling the seemingly different accounts in different places, appear to have been forty cubits high, and about four cubits diameter. The court probably at first extended all round the temple. We are informed that the court about the tabernacle was 100 cubits long and fifty broad; and as Solomon made every part of the temple about twice as large as the corresponding part in the tabernacle, we have reason to conclude that the court around the temple was 200 cubits long and 100 broad. According to this description, which is taken from the Scripture history, the temple of Solomon was by no means so large as it is commonly represented. Still, however, it was very magnificent in size and splendid in ornament. It was plundered of its treasures in the reign of Rehoboam, and repaired by Joash: it was again spoiled in the time of Ahaz and of Hezekiah; and after being restored by Josiah, was demolished by Nebuchadnezzar in the year of the world 3416, after it had stood 476 according to Josephus, and according to Usher 428 years.

The second temple was built by the Jews, after their return from the Babylonish captivity, under the direction and influence of Zerubbabel their governor, and of Joshua the high priest, with the leave and encouragement of Cyrus the Persian emperor, to whom Judea had now become a tributary kingdom. According to the Jews, this temple was destitute of five remarkable appendages, which were the chief glory of the first temple; the ark and mercy-seat, the Shechinah, the holy fire on the altar, which had been first kindled from heaven, the urim and thummim, and the spirit of prophecy. This temple was plundered and profaned by Antiochus Epiphanes, who also caused the public worship in it to cease. It was afterwards purified by Judas Maccabæus, who restored the divine worship; and after having stood 500 years, was rebuilt by Herod, with a magnificence approaching to that of Solomon's. Tacitus calls it "immensæ opulentiæ templum;" and Josephus states that it was the most astonishing structure he had ever seen, as well on account of its architecture as its magnitude, and likewise the richness and magnificence of its various parts, and the reputation of its sacred appurtenances. This temple, which Herod began to build about sixteen years before the birth of Christ, and so far completed in nine years and a half as to be fit for divine service, was at length destroyed by the Romans on the same month and day of the month on which Solomon's temple was destroyed by the Babylonians.

TEMPLES among us denote two inns of court in London, thus called because anciently the dwelling-house of the knights templars. At the suppression of that order, they were purchased by the professors of the common law, and converted into *hospitia* or inns. They are called the *Inner* and *Middle Temple,* in relation to Essex-house; which was also a part of the house of the templars, and called the *Outer Temple,* because situated without Temple-Bar.

TEMPORALITIES OF BISHOPS, are the revenues, lands, tenements, and lay-fees, belonging to bishops, as they are barons and lords of parliament.

TENASSERIM, a town and district of the Birman empire. The district extends along the sea-coast, from the eleventh to the fourteenth degrees of north latitude. A connected barrier of islands, extending 135 miles from north to south, with a strait between them and the mainland from fifteen to thirty miles broad, protects the west coast from the south-west monsoon. The capital of the province is of the same name. It was taken in 1759 from the Siamese, by Alompra, and was then large and populous; but is now almost a heap of ruins. Long. 98. 50. E. Lat. 11. 42. N.

TENBURY, a market-town of the county of Worcester, in the hundred of Doddingtree, 134 miles from London, and fourteen from the city of Worcester. It stands on the river Teme, which here forms the boundary between the counties of Salop and Worcester. The situation is low; and from having a small but rapid stream joining the river Teme at the upper end of the town, Tenbury is sometimes liable to be flooded, from the effects of which the old Gothic church has more than once suffered. It has a good corn-market, some trade in hops, cider, and perry, and a little in tanning leather and in making gloves. The population amounted in 1821 to 1668, and in 1831 to 1768.

TENBY, a town of South Wales, in the county of Pembroke, 250 miles from London. It stands on the sea-shore, on a peninsula formed by the river Severn. It was in ancient times a place of strength and importance, having been protected by fortifications, and flanked with batteries, the remains of which are still standing. It has no other employment for its inhabitants but the fisheries, and the export of coal and culm. It has of late years become a well-frequented bathing place, and has been provided with the appropriate institutions for that purpose. It is a borough, and, jointly with Pembroke, Milford, and Weston, returns one member to parliament. Its municipal government consists of a mayor, four aldermen, and eleven councillors. There is a market on Wednesday and Saturday. The inhabitants amounted in 1801 to 984, in 1811 to 1176, in 1821 to 1554, and in 1831 to 2128.

TENCE, a city of France, in the department of the Upper Loire, and in the arrondissement of Issengeaux. It stands on the river Lignon, where the Serigoul falls into it. The country around it is mountainous and thinly peopled, nor are there any large towns near it. There are some coal-mines worked in the neighbourhood. In 1836 the city contained 5730 inhabitants, some of whom find employment in making linen goods, silk goods, and lace. There are also manufactures of leather and iron ware.

TENCH'S ISLAND, a small island in the Pacific Ocean, about two miles in circumference. Long. 150. 31. E. Lat. 1. 39. S.

TENEDOS, in *Ancient Geography*, an island on the coast of Troas, at the distance of forty stadia from the continent, and eighty in compass; with a cognominal Æolian town, and a temple of Apollo Smintheus. Its origin is derived from Tennes or Tenes, who being exposed in a coffer or bog by his father Cygnus the Thracian, at the instigation of the mother-in-law, was by fate carried to this island, made king of it, and at length worshipped as a god on account of his virtues.

TENERIFFE, one of the Canary Islands, situated off the western coast of Africa. Long. 17. W. Lat. 28. 20. N. See CANARIES.

TENGALLE, a seaport of Ceylon, situated near the south extremity of the island, containing 300 inhabitants, many of whom are fishermen. Long. 80. 48. E. Lat. 6. 3. N.

TENIERS, DAVID, the elder, a Flemish painter, born at Antwerp in 1582, received the first rudiments of his art from the famous Rubens, who highly esteemed him for his promising genius, and with great satisfaction examined and commended his designs. From the school of that celebrated painter Teniers went to finish his studies at Rome. He attached himself to Adam Elsheimer for six years; and from the instructions of two such incomparable masters, he formed to himself a peculiar style, which his son afterwards cultivated so happily as to bring it to the utmost perfection. His pictures were small; and his subjects usually shops, laboratories, humorous conversations, and rural festivities. The demand for his pieces was universal; and even his master Rubens thought them an ornament to his cabinet. He died at Antwerp in 1640.

TENIERS, *David*, the younger, also an admirable painter, was the son of the former, and was born at Antwerp in 1610. He obtained the name of *Ape of Painting*, from his imitating the manner of different painters with such exactness as to deceive even the nicest judges. He greatly improved under his father, and obtained such reputation as introduced him to the favour of the great. The archduke Leopold William made him gentleman of his bed-chamber; and all the pictures of his gallery were copied by Teniers, and engraved by his direction. The king of Spain and Don Juan of Austria set so high a value on his pictures, that they built a gallery to receive them. William prince of Orange honoured him with his friendship; and Rubens not only esteemed his works, but assisted him with his advice. His principal talent lay in landscapes adorned with small figures. He also painted men drinking and smoking, chemists' laboratories, country fairs, and the like. His small figures are superior to his large ones. He died in 1694. Abraham, another son of the elder David Teniers, was equal, if not superior, to his father and brother in the expression of his characters, and his understanding the *chiaroscuro;* though he was inferior in the sprightliness of his touch, and the lightness of his pencil.

TENISON, THOMAS, archbishop of Canterbury, was born at Cottenham, in Cambridgeshire, on the 29th of September 1636; and studied at Corpus Christi College in Cambridge. In his youth he applied himself to physic; but afterward went into orders, and was some time minister of St Andrew's church, Cambridge; where he attended the sick during the plague in 1665, which his parishioners acknowledged by the present of a piece of plate. He showed himself very active against the growth of Popery, by his writings both in King Charles's and in King James's reigns. In 1680 he was presented to the vicarage of St Martin's in the Fields, London, to which parish he made several donations. He endowed a free school, and built a handsome library, which he furnished with useful books. King William and Queen Mary, in 1689, presented him to the archdeaconry of London; in 1691, he was nominated to the see of Lincoln, and in 1694 he succeeded Dr Tillotson as archbishop of Canterbury. He performed all the duties of a good primate for twenty years, and died on the 14th of December 1715.

TENNANT, SMITHSON, a distinguished chemist, born at Selby in Yorkshire, 30th November 1761, was the only child of the Rev. Calvert Tennant, younger son of a respectable family in Wensley Dale, near Richmond, and vicar of Selby. His mother was Mary Daunt, daughter of a surgeon of that town. His father had been a fellow of St John's College, Cambridge, and began to teach his son Greek when he was only five years old. He had the misfortune to lose him four years after; and before he grew up, his mother also, while he was riding with her, was thrown from her horse and killed on the spot. He was sent, after his father's death, to different schools, at Scerton, Tadcaster, and Beverley. In these he was remembered as a boy retired in his manners, and somewhat melancholy, and indolent with respect to puerile amusements. He learned but little at school, and may be considered as in a great measure self-educated; having been fond, almost as a child, of reading books of science, and of amusing himself with little experiments which he found described in them; and while he was at school at Tadcaster, he took great delight in attending a course of Walker's lectures on experimental philosophy which were given there. At Beverley he was under the care of Dr G. Croft, who had made himself known to the public by some controversial writings. Here he never entered much into the pursuits of his contemporaries, but profited by a good library belonging to the school; and among other books which he read with avidity was Sir Isaac Newton's Treatise on Optics.

He had entertained a great desire to complete his chemical studies under the immediate instruction of Dr Priestley, who was then enjoying deserved reputation for his recent experimental discoveries; but Dr Priestley's occupations did not permit him to undertake the task of directing his education, however agreeable it might have been to him to have assisted such a pupil. In the mean time he had not neglected his classics, but had acquired a sufficient knowledge of the learned languages to appreciate with correct taste the beauties of the great writers of antiquity. Notwithstanding his admiration for Dr Priestley, he was an early convert to the antiphlogistic theory of chemistry; which, with all its errors, was still a material step in the advancement of science.

In 1781 he went to Edinburgh, with the view of qualifying himself for the profession of physic, and he had the advantage of attending Dr Black's lectures, which were then in great reputation. In October 1782, he entered as a pensioner of Christ's College, Cambridge, where he became intimately acquainted with the late Professor Harwood, who had been first a surgeon in India, but having lost, by the misconduct of an agent, the fortune which he had there acquired, submitted cheerfully to the toil of recommencing his career as a physician, though already past the middle age. His talents for conversation were such as were extremely likely to captivate a young man of superior discernment; and he formed a friendship with Tennant which continued uninterrupted throughout their lives. At Cambridge he studied a little of the mathematics in the works of Newton, but much more of chemistry and botany: he already began to exercise his inventive powers in an attempt to economize the consumption of fuel in distillation, which he did not make public until twenty years after, though he mentioned it at the time to some of his friends. He also occupied himself incessantly in general, and especially in political reading, though he was far from having the air of a student; but his rooms were always in confusion, from the mixture of heterogeneous materials that were accumulated in them. His residence at Cambridge was perhaps the happiest time of his life; his spirits unwearied, his health unbroken, his feelings acute, and his conversation brilliant though simple and unaffected.

In the summer of 1784 he paid a visit to Denmark, to Sweden, and to Scheele, whose acquaintance extremely delighted him, and most of all from the simplicity of the apparatus that he employed in his researches. A year or two afterwards he went to France, and being taken ill at Paris, he was joined there by his friend Harwood, with whom he returned through Holland and the Netherlands, at the time when the bigoted people of the Low Countries were in insurrection against a philosophical despot, while Holland remained free and prosperous.

He was particularly intimate with Dr Milner, the master of Queen's College, and was recommended by his signature, together with those of Waring, Maskelyne, Jebb, and Watson, as a fellow of the Royal Society, into which he was admitted in January 1785. He removed, together with his friend Harwood, in December 1786, from Christ's College to Emanuel, and in 1788 he took the degree of bachelor of physic. In 1791 he communicated to the Royal Society his very interesting discovery of a mode of obtaining carbon from the carbonic acid. Having observed that charcoal did not decompose the phosphate of lime, he concluded that phosphorus ought to decompose the carbonate of lime; and the result fully justified his manner of reasoning.

He paid a third visit to the Continent in 1792, intending to pass through France into Italy, and arrived at Paris not long before the 10th of August; but he saw some indications of an impending convulsion, and was fortunate enough to quit Paris on the 9th. He visited Gibbon at Lausanne, and was much interested in the sagacity which this eminent writer displayed in his conversation. He proceeded to Rome and Florence, where he was fully impressed with all the admiration that he had been taught to anticipate for the treasures of ancient and modern art possessed by those cities; and in his return through Germany, he was greatly amused by the mixture of knowledge and credulity which he observed among the studious of that country. At Paris in 1793 he found every thing enveloped in gloom and overwhelmed with terror. His friend Lametherie was alarmed by the visit which he paid him; but he had the integrity to preserve for him entire some property of considerable value, with which he had intrusted him.

Upon his arrival in London, Mr Tennant took chambers in the Temple, and was in the habit of living much with some of his early acquaintance, who had adopted the law as their profession; to his own he was in great measure indifferent, neither seeking to practise it, nor being well calculated to succeed greatly in it with the public, though he studied it with attention, and took pains to make himself master of its history and philosophy, being a particular admirer of Sydenham, when considered in relation to the age in which he lived. He took his degree of doctor of physic in 1796; and in the same year he gave the Royal Society a paper on the quantity of carbonic acid afforded by the diamond, which he measured by heating it with nitre, and obtaining a precipitate by the addition of muriate of lime; and he found that the diamond afforded no more carbonic acid than an equal weight of charcoal. A subsequent communication contained the result of his observations on the action of heated nitre on gold and platina.

The love of travelling appeared to be his predominant passion. In his travels, he studied not only the natural and political history of the countries which he saw, but also their languages, and the philosophy of their etymologies. He likewise observed the peculiarities of their agriculture; and, in 1797, he determined, after visiting an agricultural friend in Lincolnshire, to devote his attention to practical farming as a serious pursuit. He purchased some allotments of unenclosed land in that neighbourhood, but he left the management of them chiefly to his friend, and afterwards made considerable additions to the property by further purchases. In 1798 or 1799, he bought a tract of newly enclosed land on the Mendip Hills, near Chedder, where he built a house, and resided for some months every summer through the remainder of his life. These speculations, though their results were at first doubtful, yet succeeded remarkably well on the whole; more especially considering the benefit which his health derived from the travelling and the exercise that they rendered necessary; but they occupied too much of his attention, and of that time which might have been employed so much more to the advantage of the public, and to his own ultimate satisfaction.

In 1799 he gave the Royal Society a paper on the magnesian limestone, or dolomite, which he considers as rather a combination than an accidental mixture; and the forms of the crystals, as they have been determined by later observers, together with the laws of definite proportions, have tended to confirm this conjecture. He found that grain will scarcely germinate, and soon perishes, when sown in the neutral carbonate of magnesia. In 1802 he published his paper on emery, which he showed to be a substance similar to the corundum or adamantine spar of China, and not an ore of iron, as had been commonly supposed. In the month of July he was making some experiments on crude platina, when he discovered in it a singular dark powder, which was left undissolved by the nitro-muriatic acid, and which was also observed the next year by Messrs Descotils and Vauquelin. In 1804 Dr Tennant showed that the powder contained two new metals, which he named *iridium* and *osmium;* and he received the Copleian medal from the Royal Society in November, as an acknowledgment of the merit of his various chemical discoveries. In 1805 and 1806 he paid two successive visits to Ireland, by way of Scotland, one of them in company with Browne the traveller, for whom he had a high esteem, and to whom he suggested the observation of the temperature of boiling water as a mode of determining the heights of mountains; a method, however, which had been long before recommended by Achard and others.

He became latterly more fond of general society than he had been in his earlier years, and he used to receive miscellaneous parties at his chambers, and to show them prints, and minerals, and novelties of various kinds. In 1812 he was persuaded to convert these mixed exhibitions into a more regular course of lectures, principally upon mineralogy, calculated especially for the ladies of his acquaintance, and which highly delighted all his audience: "Their attention was perpetually kept alive by the spirit and variety with which every topic was discussed, by anecdotes and quotations happily introduced, by the ornaments of a powerful but chastised imagination, and, above all, by a peculiar vein of pleasantry, at once original and delicate, with which he could animate and embellish the most unpromising subjects;" a circumstance which, though not of much immediate importance to the public, yet probably led him the more readily to accept the professorship at Cambridge, and would thus, if he had survived longer, have greatly extended the sphere of his utility.

In 1813 he delivered a lecture on mineralogy to the Geological Society, and gave them also an account of his analysis of a volcanic substance from the Lipari Islands, containing the boracic acid, which has since been examined on the spot by Dr Holland. In the month of May he was elected professor of chemistry in the university of Cambridge, all opposition having been withdrawn before the election. The following spring he gave his first and last course of lectures there. His introductory lecture still exists in manuscript, and is said to contain a masterly sketch of the history of the science. He communicated to the Royal Society, in 1814, a paper on the easiest mode of procuring potassium, and another on the economy of heat in distillation, proposing to heat a second boiler by the condensation of the steam of the first. In the spring and summer of this year he was occupied in searching for the origin of iodine, and he succeeded in detecting this substance in sea-water, by the test of its tarnishing the surface of leaf silver. One of the last services that he rendered the Royal Society, was in the capacity of a member of a committee which was formed in order to investigate, at the request of the government, the degree of danger that might attend the general introduction of gas-lights into the metropolis. He undertook, together with his friend Dr Wollaston, to make some experiments upon the inflammation of the gas, and they discovered conjointly the very important fact, that the gas contained in a small tube will not communicate the flame; a fact which, in the hands of Sir Humphry Davy, has been rendered productive of consequences so important to the public safety; although Sir Humphry having been abroad at the time of this investigation, and the report of the committee not having been then published, he had to rediscover this truth, and many more, in his most ingenious and successful researches.

It was early in the month of September that Dr Tennant went for the last time to France, being impatient to observe the changes which an eventful interval of twenty years had produced in that highly interesting country. He was greatly delighted with Lyon and Marseille; and, returning to Paris in November, he lingered there till February 1815. On the 15th of that month he arrived at Calais; on the 20th he went to Boulogne with Baron Bulow, in order to embark there. They did embark on the 22d, but were forced back by the wind, and meant to try again in the evening. In the mean time they took horses and went to see Bonaparte's Pillar, about a league off; and going off the road on their return, to look at a small fort, of which the drawbridge wanted a bolt, they were both thrown, with their horses, into the ditch. Bulow was only stunned, but Tennant's skull was so severely fractured, that he died an hour after.

His papers published in the Philosophical Transactions were eight in number. 1. On the Decomposition of Fixed Air, 1791, p. 182. 2. On the Nature of the Diamond, 1797, p. 123. 3. On the Action of Nitre upon Gold and Platina, p. 219. 4. On the different sorts of Lime used in Agriculture, 1799, p. 305. 5. On the Composition of Emery, 1802, p. 398. 6. On two Metals found in the Black Powder remaining after the Solution of Platina, 1804, p. 411. 7. On an easier Mode of procuring Potassium than that which is now adopted, 1814, p. 578. 8. On the Means of producing a double Distillation by the same Heat, p. 587.

9. The analysis of a Volcanic Substance containing the Boracic Acid appeared in the Transactions of the Geological Society, vol. i. 1811.

Dr Tennant was tall and slight in his person; his face was thin and his complexion light; he resembled a little the portraits of Locke; he was generally negligent in his dress, but, on the whole, agreeable in his appearance. He was distinguished for good sense, for quickness of perception, and for penetration; but, as his friend and biographer Mr Whishaw observes, in the admirably energetic sketch which he has given of his character, he was one of those who, to use the words of Dr Johnson, "without much labour have obtained a high reputation, and are mentioned with reverence rather for the possession than the exertion of uncommon abilities." "His curiosity and activity were incessant; he had a vigilance of observation which suffered nothing to escape him, and was continually gaining new information from a variety of interesting sources. But although the knowledge thus acquired was remarkable for its correctness, and complete for the purposes of its possessor, yet the industry and perseverance, by which it ought to have been embodied and made permanent for the benefit of others, were too often altogether wanting. The ardour and energy of Dr Tennant's mind co-operated unfortunately, in this respect, with his want of method and of systematic habits of application; since he was constantly pressing on to new discoveries, instead of arranging and bringing to perfection those which he had already made. His memory was a great storehouse of discoveries, and hints for discovery, of ascertained facts, probable conjectures, and ingenious trains of reasoning relative to the various important subjects upon which he had at any time been engaged. These he was continually treasuring up, with the intention of reducing them to order, and preparing them for use at a more convenient season. But that period rarely arrived. In the carelessness of intellectual wealth, he neglected those stores of knowledge which he had accumulated, and suffered them to remain useless and unproductive, till his attention was recalled to them, perhaps after a long course of years, by some new fact or discovery, some remark in conversation, or other accidental occurrence."

The effect of his peculiar cast of humour was heightened by a perfect gravity of countenance, a quiet familiar manner, and a characteristic simplicity of language. He was firmly attached to the general principles of freedom, being fully convinced "of their influence in promoting the wealth and happiness of nations; a due regard to these principles he considered as the only solid foundation of the most important blessings of social life, and as the peculiar cause of that distinguished superiority which our own country so happily enjoys among the nations of Europe." "The cheerful activity of a populous town, the improvements in the steam-engine, the great Galvanic experiments, and above all the novelty and extent of the prospects afforded by that revolution in chemical science which has illustrated our own age and country; these magnificent objects, when presented to Dr Tennant's mind, excited in him the liveliest emotions, and called for the most animated expressions of admiration and delight." "He thought himself passionate and irascible; and certainly his feelings were quick, but they were transitory." He possessed a strong sense of high honour, as well as of duty; and his liberality and humanity were evinced by some practical occurrences in which he had occasion to exercise them: his steward had defrauded him, and when the day of reckoning came, had destroyed himself: he not only forgave the debt, but provided also for the widow and her family.

"His amiable temper and unaffected desire of giving pleasure, no less than his superior knowledge and talents, had rendered him highly acceptable to a numerous and distinguished circle of society, by whom he was justly valued, and by whom his premature death was sincerely lamented. But the real extent of his private worth, the genuine simplicity and virtuous independence of his character, and the sincerity, warmth, and constancy of his friendship, can only be felt and estimated by those to whom he was long and intimately known, and to whom the recollection of his talents and virtues must always remain a pleasing though melancholy bond of union."[1] (L. L.)

TENNESSEE, one of the principal states in the North American union, extends from 81° 40′ to 90° 15′ west longitude, and from 35° to 36° 40′ north latitude, being about 110 miles in width, and about 400 miles in length in the northern part, and 300 in the southern, and includes an area of 45,000 square miles. It has Virginia and Kentucky on the north; North Carolina on the east; Georgia, Alabama, and Mississippi on the south; and Missouri and Arkansas on the west. The eastern part of the state is mountainous. The Kittatinny range, forming its eastern boundary, rises in some points to the height of about 5000 feet, or about 3000 feet above its base. To the west of this are several parallel ridges, separated by deep valleys, in which the great branches of the river Tennessee take a southerly course. These are prolongations of the Alleghany and Chestnut ridges of Virginia and Pennsylvania. The Cumberland Mountains are a prolongation of the Laurel ridge, the summits of which do not probably exceed 2000 feet in height: they are for the most part wooded to the top, but in some places are too rocky and rugged for cultivation. West of these mountains is Middle Tennessee, which is generally of a moderate hilly, and agreeably diversified surface. West Tennessee, beyond the river Tennessee, is a level or slightly undulating plain.

Rivers.

Tennessee is amply supplied with noble rivers and pure streams. The Mississippi washes the western border for a distance of 160 miles; and although its banks are generally low, and liable to inundation, the high grounds approach to its bed at several points, affording some of the most valuable sites for commercial marts to be found in its long course. These high banks, here called bluffs, have received the name of the first, second, third, and fourth Chickasaw Bluffs, from the Indian nations to whom this tract once belonged. Western Tennessee sends most of its waters directly into the Mississippi; the Obion, Forked Deer, Hatchy or Hatchee, Wolf, and Nonconnoch, empty themselves into that river. The Wolf is a rapid and broken torrent, but the others are navigable streams. All the rest of the state is drained by two great trunks into the Ohio. The Cumberland River has its sources and its termination in Kentucky, but runs for about 250 miles, with a circular sweep, in Tennessee, preserving throughout a remarkable parallelism with the Tennessee River. There is no obstacle to its navigation below Nashville, 200 miles from its mouth, and during a great part of the year steam-boats go up to Carthage; but there are several shoals between these places, which interrupt the navigation in low stages of the water. During floods, steam-boats ascend to Burkesville in Kentucky, and they have even ascended to the mouth of the South Fork. South Fork, Caney Fork, and Stone's Rivers, its principal tributaries in Tennessee, are navigable streams. The Tennessee, which has but part of its course in this state, is the principal tributary of the Ohio, and is not inferior to that river in length and volume of water. It is formed by the junction of the Clinch and Holston at Kingston, about 600 miles by its windings from its mouth. It is navigable by large steam-boats to Florence, 300 miles; but higher up, shoals and masses of rock render the navigation difficult and dangerous even for keel-boats. The sources of the Clinch and Holston are in Western Virginia, in the valleys between Kittatinny and Cumberland Mountains, and they flow nearly parallel to each other. The Watoga, the French Broad River, and its branches the Nolichucky and Big Pigeon, the Little Tennessee, and the Hiwassee, all traverse the mountain ridges at right angles to their course.

Minerals.

The eastern part of Tennessee contains indications of gold, lead, copper, and zinc, but has not been sufficiently examined to determine whether these metals exist in workable quantities. The gold occurs only in deposit mines, or in masses of quartz rock out of place. Iron ore is also found, and there are several furnaces in Carter and Rhea counties. The rock-formations of this section, between the Kittatinny and Cumberland Mountains, have generally been referred by geologists to the grauwacke or transition series, but are perhaps of a more recent age. They comprise argillaceous slates, fossiliferous limestones, red sandstones, and conglomerates. West of this is the great coal-field of Tennessee, which is co-extensive with the Cumberland Mountains, whose summit is occupied by the coal-measures. It extends into Kentucky across the Cumberland, and perhaps across the Kentucky River, and into Alabama across the Tennessee. The coal crops out at numerous points on the declivities of the mountains, and is worked in Fentress, where it is sent down the Obey River to the Cumberland; in Morgan, where Emery's River affords facilities for transporting it to the Tennessee; and in the Sequatchee valley. From these points, and from the banks of the Cumberland in Kentucky, it is carried down the rivers in flat boats as far as New Orleans. The supposed coal of Hawkins and Carter counties, and of Williamson, Davidson, and Maury counties, is, according to Professor Troost, aluminous slate, slightly impregnated with bitumen. Beneath the coal-measures is an alternation of different strata of limestone, some black, and others gray, sometimes compact, sometimes granular, and sometimes of an oolitic structure, in which are found extensive caves. One of these, on the borders of White and Warren counties, has received the name of the Big Bone Cave, from its containing bones of the mastodon and megalonyx. West of the Cumberland Mountains, the rocky strata are, in a descending series, a silico-calcareous deposit, a fetid encrinitic limestone, aluminous slate without animal remains, and limestone containing spirifers, producti, orthoceratites, &c. The silico-calcareous stratum includes the rich deposits of hydrate of iron, which is largely worked in Tennessee; the ore is abundant, and yields a metal of excellent quality. In 1836 there were twenty-seven furnaces, making about 30,000 tons of iron in a year.

Produc industry.

Agriculture forms almost the sole occupation of the inhabitants of Tennessee. A large proportion of the land is productive, and many of the valleys of East Tennessee, and much of the middle and western sections, are eminently fertile. Indian corn and cotton are the staples of the state, and a good deal of tobacco, hemp, and wheat are raised. Cotton thrives in almost every part except in the north-eastern triangular section, and the crop is about 150,000 bales; but the climate of Tennessee is not so well adapted for this plant as that of the states south of the thirty-fifth parallel of latitude. The new lands of the western part have, however, been chiefly devoted to this culture. The tobacco crop is about 5000 hogsheads. In East Tennessee, grazing is much attended to, and great numbers of live stock are driven out of the state to the eastern markets. The pine forests of this section of the country also afford tar, spirits of turpentine, rosin, and lamp-black. Whiskey, coarse linens, cotton bagging, live stock, pork, butter, saltpetre, gunpowder, flour, coal, and fruits, with cotton, maize, and tobacco, constitute the exports of Tennessee. The value of the exports is estimated at 8,000,000 dollars. The estimated value of real property in the state is 150,000,000 dollars.

---

[1] [Wishaw in] Thomson's Annals, vol. vi. 1815, p. 1. 80.

The population of Tennessee is inconsiderable when viewed with reference to the extent and productive capacities of the state, but its amount is surprising when we consider that it occupies a region which about half a century ago was an uninhabited wilderness. The current of immigration began to set steadily into Tennessee soon after the peace of 1783, chiefly from the eastern part of North Carolina; and during the forty years from 1790 to 1830 the rate of increase was 1805 per cent. Of late years Tennessee has sent forth thousands of planters with their forces to the south-western and western states; but it is yet capable of supporting seven times its actual population, which is only fifteen to the square mile. Slavery, that dark stain upon the American character, has existed here from the first settlement of the state, and the slaves form rather more than one fifth of the whole population.

Population at different Periods.

	Whites.	Slaves.	Free Coloured.	Total.
1790	32,013	3,417	361	35,791
1800	91,709	13,584	309	105,602
1810	215,875	44,535	1,317	261,727
1820	339,727	80,107	2,979	422,813
1830	535,746	141,603	4,555	681,904

The elevated valleys of East Tennessee belong to the great Alleghany table-land of the United States, and are from 1000 to 1200 feet above the level of the sea, although from 1000 to 1500 feet below the mountain crests which rise between them. The first settlements by the whites were made in these valleys, but there is no large town in this section. Knoxville, the most important, has a population of about 2000 souls, and is a place of considerable trade. The town was the capital of the territory south-west of the Ohio, and of the state, till 1802, and it contains three or four churches, the halls of East Tennessee College, a female academy, court-house, &c. The other villages of East Tennessee, such as Blountville and Rogersville in the valley of the Holston, Clinton and Kingston on the Clinch, Jonesboro on a branch of the Nolichucky, and Calhoun on the Hiwassee, have only from 500 to 800 inhabitants.

Middle Tennessee, although settled at a later period, is more populous than East Tennessee, but it contains no considerable town except Nashville. Winchester, Fayetteville, and Pulaski, are thriving little villages in the south, in the valley of the Elk. The last named has about 1200 inhabitants, the two others about 800; Fayetteville is at the head of the navigation on the river. Columbia, on Duck River, is a flourishing town with 1500 inhabitants, and is the seat of Jackson College. To the north is Franklin, a busy, growing town, on the Harpeth, with a population equal to that of Columbia. Murfreesboro, with a population of 1000, was at one time the capital of the state. Carthage, on the Cumberland River, at the mouth of the Caney Fork, has 800 inhabitants. On the higher branches of the Fork are the villages of Sparta and Macminnville.

The city of Nashville, the capital of the state, and its commercial emporium, is advantageously and pleasantly situated on the left bank of the Cumberland, in a highly fertile and picturesque region. The navigation of the river below the city is only interrupted for a short time, and the products of an extensive tract are brought down on its bosom. The trade and business are extensive; there are about fifteen steam-boats employed on the river, besides great numbers of keel-boats. Among the manufacturing establishments are several brass and iron founderies, rolling mills, tanneries, &c. The town was founded in 1784, but the site had been occupied as a trading post by the French in the middle of the century; and in 1779 it was occupied by a body of Americans, by whom it was called the French Lick. In 1830 the population was 5566, including 2000 slaves; and in 1836 it amounted to about 8000. Nashville is the seat of a university, and its other educational institutions are numerous and well supported. The Hermitage, the plantation of ex-president Jackson, is about twelve miles above Nashville. Gallatin, higher up the valley of the Cumberland, and Clarksville, on the river below, are flourishing villages.

Tennessee.

West Tennessee, lying between the Tennessee and Mississippi Rivers, received its first white settlers in 1819, a few years before which time this tract had been ceded to the United States by the Chickasaws. At present it contains a population of about 100,000 souls, and has several flourishing towns. The soil is light and sandy, and well adapted to the raising of cotton. In this division of the state, several towns have been founded; and among these are Jackson, on the Forked Deer River, with 1000 inhabitants; Bolivar, a busy and growing town, at the head of navigation on the Big Hatchee; Lagrange, on the Wolf River; Ashport, on the first Chickasaw Bluff, below the mouth of the Forked Deer; Randolph on the second Chickasaw, below the mouth of the Big Hatchee, with a good harbour for steam-boats in all stages of the water. Memphis, which is the most important town of this tract, stands at the mouth of the Wolf River, on the fourth Chickasaw Bluff, which is thirty feet above the highest floods, and seventy-five feet above low water. At some future day, this is doubtless destined to be one of the great commercial emporiums of this vast valley. Its population at present exceeds 2000, and is rapidly increasing with its growing business. It possesses a safe and commodious harbour, and its site is admirably adapted for a large commercial town. Three miles below, at the lower end of the Bluff, the city of Girard has lately been founded on the site of Fort Pickering. The Chickasaw Bluffs, or elevated districts, are four in number, and are the only points where the river-banks are above the reach of inundation in this state.

Government.

A constitution for Tennessee was first adopted by a convention held at Knoxville in 1796, and was afterwards revised and adopted, with considerable modifications, by a convention assembled in Nashville in 1834. The supreme executive power is vested in a governor, who is chosen by the people for the term of two years, and has the power of granting reprieves and pardons. He is also commander-in-chief of the army and navy of the state, but has no official patronage or voice in legislation. The legislature, styled the General Assembly, consists of a senate of twenty-five members, and a house of representatives of seventy-five, chosen for the term of two years. The former are apportioned among the senatorial districts, and the latter among the counties, in the ratio of the number of voters in each. The pay of the senators and representatives is four dollars per day. The judiciary power is vested in a supreme court and inferior courts, and the judges are elected by joint ballot of the two houses of the legislature; the superior judges holding office for twelve years, and the inferior judges for eight. Sheriffs and coroners are appointed by the county courts. Every free white male citizen who has resided in the county in which he offers to vote during the six months immediately preceding an election, has the right of suffrage, and all elections are by ballot.

Education.

The state has a large school fund, arising chiefly from the proceeds of the sales of public lands, amounting in 1837 to about 800,000 dollars, in addition to a large quantity of land not then sold. The income of this fund is distributed, by the common-school commissioners of each county, among such school districts as have provided school-houses, in proportion to the number of white children between the ages of six and eighteen years in each. There are at present about 1000 free or common schools in the state, and efforts are making to render the system more complete and efficient. There are sixty-two academies in the state, one having been endowed in each county by grants of public land; but many of these are not in actual operation. The collegiate institutions are, the university of Nashville, Greenville College at Greenville, Washington College in Washington county, East Tennessee College at Knoxville, and Jackson College at Columbia. There is also a Presbyterian theological seminary at Maryville. In 1839, fifty newspapers were published in this state.

Religious sects. The constitution of Tennessee declares that all men have a natural and indefeasible right to worship Almighty God according to the dictates of their own conscience; that no preference shall be given by law to any religious establishments or modes of worship; and that no religious test shall ever be required as a qualification for any office or public trust; but it also provides that no person who denies the being of God, or a future state of rewards and punishments, shall hold any office in the civil department of the state. The Methodists and Baptists are the most numerous sects, the former numbering about 30,000, and the latter about 20,000 communicants. The Presbyterians have 120 churches and 10,000 communicants, exclusive of the Cumberland Presbyterians, who are also numerous. The Episcopalians have one bishop and twelve ministers; and there are Roman Catholics, Lutherans, Friends, &c.

TENNIS, a play at which a ball is driven by a racket.

TENSE, in *Grammar*, an inflection of verbs, by which they are made to signify or distinguish the circumstance of time in what they affirm.

TENT, in *War*, a pavilion or portable house. Tents are made of canvass, for officers and soldiers to lie under when in the field.

TENTERDEN, a town in the hundred of the same name, and the lathe of Scray, in the county of Kent, thirty-seven miles from London. It stands on a hill, and the lofty steeple of its church is distinguished from every part of the extensive district by which it is surrounded, and was formerly used as a beacon. At the first introduction of the woollen manufacture, it was an industrious place; but that occupation has long ceased. It is an ancient borough, and is governed by a mayor, four aldermen, and eleven councillors. There is a market held on Friday. The inhabitants amounted in 1821 to 3259, and in 1831 to 3177.

TENURE, in *Law*, signifies the manner in which lands or tenements are held, or the service which the tenant owes to his lord. Of this kingdom almost all the real property is by the policy of our laws supposed to be granted by, dependent upon, and held of, some superior lord, by and in consideration of certain services to be rendered to the lord by the tenant or possessor of this property. The thing held is therefore styled a *tenement*, the possessors of it *tenants*, and the manner of their possession a *tenure*. Thus all the lands in the kingdom are supposed to be held, mediately or immediately, of the king, who is styled the *lord paramount*, or above all. Such tenants as held immediately under the king, when they granted out portions of the lands to inferior persons, became also lords with respect to those inferior persons, as they were still tenants with respect to the king; and thus partaking of a middle nature, were called *mesne* or *middle lords*.

TEOS, one of the twelve Ionian cities, was situated on the south side of the Ionian peninsula, and distinguished by being the place where the poet Anacreon and the historian Hecatæus were born.

TERAMO, a city of Italy, the capital of the Neapolitan province Abruzzo Ulteriore I. It stands on the river Tordino, and is fortified. It is the seat of a bishop, and, besides the cathedral, has nine churches, with 9250 inhabitants, who have considerable trade in corn and in wine, and other products of the soil.

TERCERA, one of the largest of the Azores, or Western Islands, lying in the Atlantic Ocean. It is about forty miles in circumference, and is surrounded with craggy rocks, which render it almost inaccessible. The soil is fertile, abounding in corn, wine, and fruits; and the inhabitants have plenty of cattle to supply the ships that touch there. Their principal trade is in wood. The inhabitants are lively, addicted to gallantry, and are said to be extremely revengeful. It is subject to Portugal, and Angra is the capital town. Long. 27. 1. W. Lat. 28. 45. N.

TEREK, a considerable river of Asiatic Russia, in the government of Caucasus, which has its rise in the deep recesses of the snow-covered mountains in the loftiest part of the Caucasian chain, on the frontier of Circassia and Georgia. It flows with a rapid course northward towards the plains, whence it turns eastward, and flows along the foot of the mountain range, till, after passing Kizlar, it divides into three branches, and falls into the Caspian. It forms the boundary between the Russian territory and the Caucasian tribes; and, for the purpose of overawing them, a number of forts has been built along the river by Russia. It flows through a picturesque country; and its banks are adorned with fine forests of oak, while the lower parts produce vines, mulberries, and other fruit trees.

TERENCE, or Publius Terentius, a comic poet of great celebrity, was born at Carthage in the year 192 before the commencement of the Christian era. At an early age he became a captive, and was sold as a slave to Terentius Lucanus, a Roman senator, to whom he appears to have been indebted for a learned education. His manners and accomplishments recommended him not only to his master, but likewise to other men of rank, whose names have been recorded. Having been manumitted, he attained to great eminence as a writer of Latin comedies. He was honoured with the friendship of Lælius, and of Scipio the son of Paulus Æmilius; and his dramas are even supposed to have derived some of their chief beauties from their patrician pens. Such insinuations have not been uncommon in various eras of literary history; but some doubt may reasonably be entertained whether Scipio or Lælius could have produced even the second-rate scenes of Terence's comedies. They exhibit a uniform vein of elegant simplicity, in which we discover no reason to suspect a divided property. His plots are derived from Greek sources, chiefly from Menander; but the terse Latinity and graceful diction are peculiarly his own. Cæsar considered the want of pungent humour, the *vis comica*, as the chief defect of his dramas.

> Lenibus atque utinam scriptis adjuncta foret vis
> Comica, ut æquato virtus polleret honore
> Cum Græcis, neque in hac despectus parte jaceres.

The comedies of Terence appear to have been very successful on the stage, but he did not long continue his prosperous career. According to Eusebius, he died in Arcadia; and Suetonius refers his death to the consulship of Cn. Corn. Dolabella and M. Fulvius Nobilior, that is, to the year 159 before Christ. According to this chronology, he must only have attained the age of thirty-three; but the latter writer states that he had not completed his thirty-fifth year. The circumstances of his death are variously related, and one account ascribes it to shipwreck. He left an only daughter, who became the wife of a Roman knight, and inherited a garden of twenty acres in the Via Appia.

He had a tawny complexion, with a slender frame, and a moderate stature.

Of the six comedies of Terence, the editions are very numerous, and not a few appeared before the termination of the first half century of printing. The *editio princeps*, a folio without date, is supposed to have been printed at Strasburg by Mentelin. Seventeen editions, the first in 1517, proceeded from the Aldine press. Of the earlier editions, the most important is that of Gabriel Faërnus, Florent. 1565, 8vo. Faërnus was a man of taste as well as learning, and, being himself a very skilful versifier,[1] possessed some eminent qualifications as an editor of Terence. To his text many succeeding editors have chiefly adhered. Another valuable edition was published by Lindenbrog, Paris. 1602, 4to, Francof. 1623, 4to. Passing many others, we arrive at the edition of Bishop Hare, Lond. 1724, 1725, 4to. It was speedily followed by that of Bentley, Cantab. 1726, 4to, Amst. 1727, 4to. Another elaborate edition, differing however in many respects, was about the same time published by Westerhov, Hag. Com. 1726, 2 tom. 4to. There are many subsequent editions, some of a very recent date. One edition was professedly published for men of taste; "in usum elegantiorum hominum edidit F. H. Bothe." Berolini, 1806, 8vo. A good translation of Terence, into blank verse, was executed by the elder George Colman, Lond. 1765, 4to.

TERGOVISTA, a town of European Turkey, in Walachia, in the district of Zara de Suss, on the river Jalomiza. It is situated in a pleasant and fruitful district, and was once the residence of the waiwodes of Walachia, and still continues the seat of government of the district. It contains several churches, two convents, and some very large but rather dilapidated houses, and a population of 5400 persons. It is sixty-four miles south-east from Hermanstadt, and 180 north-east from Belgrade. Long. 25. 29. E. Lat. 45. 3. N.

TERKI, a fortress built by Russia at the mouth of the Tumenka, one of the branches of the Terek. The place was once of great importance, but was afterwards razed to the ground. The present fort contains only a small garrison, and a few inhabitants.

TERM, in *Grammar*, denotes some word or expression in a language. The word *term*, *terminus*, is borrowed metaphorically, by the grammarians and philosophers, from the measurers or surveyors of lands: as a field is defined and distinguished by its *termini*, or limits, so is a thing or matter by the word or term by which it is denoted.

TERM, in *Law*, is generally taken for a limitation of time or estate; as, a lease for a term of life or years. Term, however, is more particularly used for the time when the English courts of justice are open; in opposition to which, the rest of the year is called vacation.

TERMINATION ISLAND, in the South Pacific Ocean, so named by Captain Vancouver, as being the termination of his researches on the south-west coast of New Holland, near which it lies. Long. 122. 8. E. Lat. 34. 32. S.

TERMINI, a city of the island of Sicily. It stands on the northern shore of the island, near the mouth of the river Leonardo. Its appearance from the sea is very respectable. It is surrounded with walls rapidly tending to decay, but is protected by a castle on a high rock, which commands the town and coast. The streets are narrow and filthy, but there are some tolerable buildings; and it has the convenience of a good carriage-road to the metropolis, twenty-four miles distant. In ancient times it was celebrated for its thermal baths, supplied by chalybeate sulphureous springs, of the heat of 121° of Fahrenheit. Though in bad repair, they are resorted to for the cure of rheumatic complaints. The city contains 12,800 inhabitants, who derive considerable profit from the anchovy fishery, and from the exportation of oil, olives, wine, sumach, corn, and rice.

TERMINI, in *Architecture*, denote a kind of statues or columns, adorned on the top with the figure of a man's, woman's, or satyr's head, as a capital; and the lower part ending in a kind of sheath or scabbard.

TERMINUS, in Pagan worship, an ancient deity among the Romans, who presided over the stones or land-marks, called *termini*, which were held so sacred that it was accounted sacrilege to move them; and as the criminal became devoted to the gods, it was lawful for any man to kill him. The worship of this deity was instituted by Numa Pompilius, who, to render land-marks, and consequently the property of the people, sacred, erected a temple on the Tarpeian Mount to Terminus.

TERNATE, one of the smaller Molucca Isles, on the west coast of Gilolo, about twenty-five miles in circumference, and formerly the seat of sovereignty over all the adjacent Molucca islands, Tidore, Bachian, Motir, and Machian, which are properly the Moluccas, being the islands which originally produced the finer spices; and in the woods of Ternate larger nutmegs are still found than any that are produced in Banda. The king of Ternate was one of the most potent sovereigns in the Asiatic islands, extending his dominion over seventeen or eighteen islands, and maintaining a considerable naval force. When the Portuguese were driven from these islands by the Dutch in 1607, the native princes were forced to submit to their conquerors, who interdicted them from trading with any other European nation. The island contains a lofty peak, which sometimes discharges flames. Ternate formerly carried on a considerable trade with China, and with the other Asiatic islands. At present its chief produce is rice. It was taken from the Dutch in the course of the revolutionary war, but was restored at the peace of Amiens. It was again taken in 1810, and was restored to the Dutch with their other possessions in India by the peace of Paris in 1814.

TERNI, a town of Italy, in the papal delegation of Spoleto. It stands between two branches of the river Nera, in a delightful valley surrounded with olive, pomegranate, and mulberry trees. It is the seat of a bishop, has a cathedral, several parish churches, and five monasteries, with 5100 inhabitants. In the episcopal garden are the remains of an amphitheatre, and in the church of St Salvador those of a temple of the sun. Near to it is the celebrated cascade of the Marmora, where the river Belino, by three successive falls of 300 hundred feet, empties its water into the Nera. Long. 12. 34. E. Lat. 42. 34. N.

TERPANDER, a celebrated Greek poet and musician. The Oxford marbles record that he was the son of Derdeneus of Lesbos, and that he flourished in the 381st year of these records; which nearly answers to the 27th Olympiad, and 671st year before Christ. The marbles likewise inform us that he taught the *nomes*, or airs, of the lyre and flute, which he performed himself upon this last instrument, in concert with other players on the flute. Several writers affirm that he added three strings to the lyre, which before his time had but four. Among the many signal services which Terpander is said to have rendered to music, none was of more importance than the notation that is ascribed to him for ascertaining and preserving melody, which before was traditional, and wholly dependent on memory. The invention, indeed, of musical characters, has been attributed by Alypius and Gaudentius, two Greek writers on music, and upon their authority by Boethius, to Pythagoras, who flourished fully two centuries after Terpander. But Plutarch, from Heraclides of Pontus, assures us that Terpander, the inventor of nomes for the cithara, in hexameter verse, set them to music, as well as the verses of Homer, in order to sing them at the public games. Clemens Alexandrinus, in telling us that this musician wrote the laws of Lycurgus in verse, and set them to music, makes use of the same expression as Plutarch; which seems clearly to imply a written melody. After enumerating the airs which Terpander had composed, and to which he had given names, Plutarch continues to speak of his other compositions; among which he describes the proems, or hymns for the cithara, in heroic verse. Of the works of this poet only a few fragments now remain.

---

[1] See a very elegant volume entitled "Gabrielis Faërni Cremonensis Fabulæ centum, ex antiquis auctoribus delectæ carminibusque explicatæ, et ejusdem Carmina varia." Parmæ, 1793, 4to.

TERRA Australis Incognita, a name for a supposed unknown continent lying towards the south pole. It was an object of search to several navigators, among others to Captain Cook, who made the circuit of the Southern Ocean in a high latitude, and came to the conclusion that there could be no continent in that quarter, unless so far south as to be out of the reach of navigation; but he considered the excessive cold and vast fields of ice which he encountered, as proofs of the existence of land near the pole. This question has, however, been set at rest by the recent discoveries of the French under Captain D'Urville, and the American exploring expedition under Lieutenant Wilkes, which by an extraordinary coincidence were made on the same day (Jan. 19, 1840), at the distance of 720 miles from each other. Lieutenant Wilkes states that his discoveries have led him to the following conclusions: "1st, From our discoveries of the land through forty degrees of longitude, and the observations made during this interesting cruise, with the similarity of formation and position of the ice during our close examination of it, I consider that there can scarcely be a doubt of the existence of the Antarctic Continent, extending the whole distance of seventy degrees from east to west. 2d, That different points of the land are at times free from the ice barrier. 3d, That they are frequented by seals, many of which were seen, and offer to our enterprising countrymen engaged in those pursuits, a field of large extent for their future operations. 4th, That the large number of whales of different species seen, and the quantity of food for them, would designate this coast as a place of great resort for them. The fin-backed whale seemed to predominate.

"We proceeded on our cruise to the northward and eastward, with strong gales, until we reached the latitude of certain islands laid down on the charts as the Royal Company's Islands, about six degrees to the westward of their supposed locality. I then stood on their parallel, and passed over their supposed site; but we saw nothing of them, nor any indication of land in the vicinity. I feel confident, as far as respects their existence in or near the longitude or parallel assigned them, to assert that they do not exist. The last ice island was seen in lat. 51° south."

TERRACINA, a city of Italy, in the papal delegation of Frosinone. It stands on the sea-shore, at the foot of a hill, where the Pontine marshes terminate. It is the seat of a bishop, has a cathedral, and is surrounded with walls; and being a frontier place, is furnished with a garrison. It is deemed unhealthy, but contains 4170 inhabitants. Near to it are the façade of a temple of Jupiter, and the remains of the palace of Theodoric. It has wood near it, which yields cork. Long. 13. 13. 2. E. Lat. 41. 18. 14. N.

TERRA-NOVA, a city of the island of Sicily, in the province of Noto, on a hill in a healthy situation, on the sea-shore, near the mouth of the river Graceio. It is well built, and contains 8290 inhabitants, who cultivate cotton, and collect much silk, and trade extensively in wheat, barley, soda, sulphur, and pulse of various kinds.

TERRASSON, John, born at Lyon in 1669, distinguished himself in the dispute concerning Homer, between La Motte and Madame Dacier, by writing a "Dissertation Critique sur l'Iliade d'Homère." Paris, 1715, 2 tom. 12mo. Among other works, he likewise wrote a political and moral romance called *Sethos*. It is a publication of considerable learning and ability. He published a French translation of Diodorus Siculus. Paris, 1737–44, 7 tom. 12mo. Terrasson is commonly described as *Abbé*, but he only appears to have been in sub-deacon's orders. In 1721 he became professor of Greek and Latin in the College of France. Having outlived his memory, he died at Paris on the 15th of September 1750.

TERRE Napoleon, a tract of coast on the south shore of New Holland, first explored by the French navigator Captain Baudin in Le Géographe. According to Captain Flinders, it is comprised between Lat. 37. 36. and 35. 40. S. and between Long. 140. 10. and 138. 58. E. making about fifty leagues of coast, in which, Captain Baudin observes, there is neither river, inlet, nor place of shelter; and it has, besides, an appearance of extreme barrenness.

Terre *Verte*, in the colour-trade, the name of a green earth much used by painters, both singly for a good standing green, and in mixture with other colours. The name is French, and signifies green earth.

TERRIANI or Terrai, a district in Northern Hindustan, situated about the twenty-seventh degree of north latitude, partly comprehended in the British dominions, and partly in those of Nepaul. The word properly signifies marshy land, and is sometimes applied to the flats lying below the hills in the interior of Nepaul, as well as to the low tract bordering on the company's northern frontier. To the south it is bounded by Gorackpoor, Bettiah, and Tyrhoot. The Terriani of Nepaul is confined between the Gunduck and the Teesta, and is divided into five soubahs or governments, from which however the rajah of Nepaul does not draw any considerable revenue, owing partly to mismanagement, and partly to the low state of the population from the unhealthiness of the country. The western Terriani contains inexhaustible forests of the most excellent timber. The pines of Beehiacori, and the saul trees both of that and of the Jhurjoory Forest, are not surpassed anywhere for straightness or durability, and might be floated south on the Boora Gunduck. Pure turpentine of the Sulla pine might also be procured.

So extremely unhealthy is this dreary tract, that Heber (vol. ii. p. 157) mentions, on the authority of those who had resided in the vicinity, that not only the inhabitants, but every thing which has the breath of life, instinctively deserts it from the beginning of April to October. The tigers go up the hills, and the antelopes and wild hogs make excursions into the cultivated plain; and those who are obliged to traverse the forests during the intervening months, such as military officers or Dak bearers, agree that not so much as a bird can be heard or seen in the frightful solitude. In the time of the heaviest rains, and while the water falls in torrents, the country may be passed in comparative safety. It is during the extreme heat, and while the exhalations are ascending from the damp ground after the rains have ceased, namely, in May, the latter end of August, and the early part of September, that the climate is most fatal. The season is more healthy in October, when the animals return, and the woodcutters and cowmen venture, though cautiously. From the middle of November to March, troops pass and repass without any danger. The forest extends at the foot of the lowest hills in a long black level line, so black and level that Heber remarks it might seem to have been drawn with ink and a ruler. Fever and ague are the diseases to which this district is liable. The inhabitants are few, and unhealthy in their appearance, and are rather decreasing, owing to the fatality of the climate. The principal rivers are the Bhagmutty, the Bukkia, and the Jumne, besides many nullahs and inferior streams.

TERROWEH, a town and fortress of Hindustan, in the province of Allahabad, district of Bundelcund. Latitude not ascertained.

TERTULLIAN, or Quintus Septimius Florens Tertullianus, one of the Latin fathers, was born at Carthage about the middle of the second century. Dr Allix, in his "Dissertatio de Tertulliani Vita et Scriptis," has remarked that those who suppose him to have flourished about the year 160, have referred his birth to too early a period. His father was a centurion in the legion of the proconsul. The son was well instructed in elegant as well as useful learning, and in particular acquired much skill in the civil law. Having renounced the errors of paganism, he distinguished himself by his able apology for the Christians. It appears from his works that he was married. He became a presbyter of the church of Carthage, and afterwards paid a visit to Rome, where he was a spectator of the games celebrated by the emperor Severus in the year 204. On his return, he embraced the errors of Montanus. He then thought proper to assume the *pallium*, or robe of the ancient philosophers, and to defend his conduct in a learned and singular tract "De Pallio." He at length relinquished his connexion with the Montanists, but still retained some peculiar opinions. Tertullian reached an advanced age, and we may perhaps place his death about the year 240. He was a man of much fervour and ingenuity, conjoined with various learning; but his works contain many erroneous, and some pernicious opinions, among which we may class his notion as to the benefit of prayers for the dead. He writes in an African style of eloquence, and his meaning is not unfrequently obscure. Lactantius, no mean judge, has censured him as deficient in ease and perspicuity. The earliest edition of his works was published by Beatus Rhenanus, Basil. 1521, fol. Many editions followed, but we shall only refer the reader to that of Rigault, or Rigaltius, Paris. 1634, fol.[1] A separate volume, containing the commentaries of former editors, was added in 1635. Some of his treatises have received much learned illustration in a separate form; particularly the Apologeticus from Heraldus, Lutet. Paris. 1613, 4to, and from Havercamp, Lugd. Bat. 1718, 8vo, and the tract "De Pallio" from Salmasius, Lugd. Bat. 1656, 8vo. This tract, very brief in itself, is suffused with an immense stream of erudition.

TERUEL, a department of the southern division of the province of Aragon, in Spain, a rich district, watered by the streams of the rivers Guadalaviar and Alhambra. The borders of the department are mountainous and sterile, but the valleys are very productive. The capital is a city of the same name, upon the river Turia, at the point where it falls into the Alhambra. It is situated on a hill, is surrounded with walls, and is the seat of a bishop. It has a cathedral, seven other churches, five convents for males and females, and 1200 houses, with 5600 inhabitants, who deal largely in fine wool, and make some woollen cloths. Near the city are the remains of a noble aqueduct constructed by the Romans. There are also mines of quicksilver at some distance from the city, which were formerly worked, but are now abandoned. Lat. 40. 38. 2. N.

TERUNCIUS, a very small brass coin, in use among the Romans.

TERVENGARY, a small Mahommedan town of Hindustan, in the province of Malabar, situated on the banks of a river which is navigable in the rainy season thirty-two miles for canoes. Near this town Tippoo's forces were decisively defeated by Colonel Hartley's army. It is twenty-three miles south by east from Calicut. Long. 76. E. Lat. 11. 2. N.

TERZETTO (*Ital.*), a musical composition for three *obligati* parts, vocal or instrumental. An instrumental terzetto is also called a *trio*.

TESCHEN, a circle of the Austrian principality of Moravia, usually called a duchy. It is bounded on the north by Prussian Silesia, on the east by Gallicia, on the south by Hungary, and on the west by Perau. It extends over 756 square miles, and contains nine cities or towns, 279 villages, and 161,500 inhabitants. The capital is the city of the same name, on the beautiful river Elsa. It is well built, is surrounded with walls, and contains one Lutheran and four Catholic churches, and a collegiate institution belonging to each religion. It is a place of considerable trade, and has manufactures of linen and woollen. The situation is fine, and the country around fertile. It is celebrated for the treaty of peace between Austria and Prussia, concluded in 1779. The inhabitants amount to 5860. Long. 12. 27. E. Lat. 49. 41. N.

TESHOO Loomboo is, properly speaking, a large monastery, consisting of three or four hundred houses, the habitations of the gylongs or priests, besides temples, mausoleums, and the palace of the lama or sovereign pontiff of this idolatrous religion of the east. This is the seat of his authority, and the capital of all that part of Tibet immediately subject to him. The buildings are all of stone, two stories high, flat roofed. The fortress of Shiggatzee Jeung stands on a prominent ridge of the rock, and commands the pass. From this point roads diverge to Bootan and Bengal, to Lahdack and Cashmere; to the mines of lead, copper, cinnabar, and gold; to Nepaul, to Lassa, and China. Catmandoo, the capital of Nepaul, is estimated to be 400 miles distant. The plain extends fifteen miles on a direct level, and is encompassed on all sides by rocky hills. It is intersected by the river Painomchieu, which at a small distance joins the Brahmaputra. This great river flows here, in a widely extended bed, through many channels, forming a multitude of islands, and its principal channel is narrow, deep, and never fordable. The monastery of Teshoo Loomboo contains no less than 3700 priests for the performance of daily prayer in the temple, and four lamas chosen to superintend the ceremonies. Under the direction of the monastery, there is an extensive establishment for the manufacture of images, in which they excel the Chinese.

TESSELATED Pavements, those of rich mosaic work, made of curious square marbles, bricks, or tiles, called *tesselæ* from their resembling dice.

TESSERA, in Roman antiquity, denoted in its primary sense a cube or die; so called from the Greek word τέσσαρα, or τέσσερα, *four;* respect being had to its number of sides, distinct from the two horizontal planes above and below. And it was thus distinguished from the talus, which being round at each end, contained only four planes or faces on which it could stand; and therefore when thrown it had no more than two side faces in view. Hence *ludere talis et ludere tesseris* are spoken of by Roman writers as two different games. The word *tessera* was applied to many other things, not so much from a similitude in the figure, as from the relation they bore to some other things of which they were the sign or token; as the points on the upper plane of the die denoted the good or ill success of the cast.

The *tessera hospitalis* was either public or private. As to the former, we find among the inscriptions published by Gruter instances of two municipal towns which put themselves under the patronage of the Roman governor; and the reciprocal engagement between them, engraved on two copperplates, of an oblong form, with a pediment at the top, is called in both *tessera hospitalis*. The design of it was to cultivate or maintain a lasting friendship between private persons and their families, and gave a mutual claim to the contracting parties and their descendants, of a reception and kind treatment at each other's houses, as occasion offered; for which end those tesseræ were so contrived as best to preserve the memory of that transaction to posterity. And one method of doing this was by dividing one of them lengthwise into two equal parts, upon each of which one of the parties wrote his name, and interchanged it with the other. From this custom came the prevailing expression "tesseram hospitalem confringere," applied to persons who had violated their engagements.

---

[1] See Du Pin, Bibliothèque des Auteurs Ecclesiastiques, tom. i. p. 106. Dr Kaye, bishop of Lincoln, has published a work of considerable value, under the title of "The Ecclesiastical History of the second and third Centuries illustrated from the Writings of Tertullian." Cambridge, 1826, 8vo.

The *tesseræ frumentariæ* were small tallies given by the emperors to the populace at Rome, entitling them to the reception of a quantity of corn from the public at stated seasons. The person who had the inspection of these was called *tesserarius*. They were made of wood and of stone. There was another kind of tessera, which entitled persons to a sight of the public games and other diversions, usually made in an oblong form.

The *tessera militaris* was a signal given by the general or chief commander of an army, as a direction to the soldiers for executing any duty or service required of them. This, upon urgent occasions, was only vocal; but in ordinary cases it was written on a tablet, commonly made of wood. Besides these civil and military tesseræ, there are others which relate to religious affairs, and may be called *sacred*.

TESSIN or TICINO, a canton of Switzerland, in the most southern part of the confederation, extending in longitude from 8° 5′ to 8° 58′ east, and in latitude from 45° 46′ to 46° 33′ north. It is bounded on the north by Uri, on the north-east by the Greybunden, on the south-east and south by Venetian Lombardy, and on the south-west and west by the Sardinian dominions. It is 781 geographical square miles in extent, contains twelve market-towns and 212 villages, thirteen monasteries, and seven nunneries, with 113,923 inhabitants in 1838, who all adhere to the Romish church. They are all of the Italian race, and speak that language, except about a thousand, who use a corrupted German, and live in one of the valleys, unconnected with their fellow-citizens. The contingent to the force of the confederation is fixed at 1804, and the pecuniary contribution at L.1127. 10s. It has lately received a new constitution of the representative kind, with a president changed monthly, and an assembly of 114, with another of eleven members. It is a most delightful and picturesque district, where, especially on the southern side, nature is exhibited in the wildest and most fantastic forms, intermingled with the valleys, which present less rugged beauty, and many of them a high degree of fertility. From St Gothard, 9000 feet high, the southern side displays the lakes scattered on the declivities. Although on the mountains there is little or no cultivation, with scarcely any productions except timber, and in a few summer months some butter, yet, on the declivities towards Italy, agriculture is carried on with great success. In some of the valleys prodigious crops of maize are gathered, in others the mulberry trees abound, and much silk is collected; and in most of them wine is extensively produced, though it is not well managed. Hemp, flax, tobacco, and all kinds of fruit, are likewise abundant. By the construction of roads, this canton has recently become more easily accessible, and the inns are much improved.

TESSOUWA, a considerable town in Africa, situated east of Mourzouk, the capital of the kingdom of Fezzan. Near this town a deep and rapid stream is said to have existed, but was overwhelmed by the moving sands so frequent in Africa.

TEST ACT is the statute 25 Car. II. cap. 2, which directs all officers, civil and military, to take the oaths, and make the declaration against transubstantiation, in the court of King's Bench, or Chancery, the next term, or at the next quarter-sessions, or (by subsequent statutes) within six months after their admission; and also within the same time to receive the sacrament of the Lord's Supper according to the usage of the church of England, in some public church, immediately after divine service or sermon, and to deliver into court a certificate thereof signed by the minister and churchwarden, and also to prove the same by two credible witnesses, upon forfeiture of L.500, and disability to hold the said office. This act, so incompatible with the principles of toleration, and injurious to the rights of dissenters, has happily been repealed by 9 Geo. IV. cap. 17.

TESTAMENT, or LAST WILL. Testaments, both Justinian and Coke agree, are so called, because they are *testatio mentis;* an etymon which seems to savour too much of conceit, it being plainly a substantive derived from the verb *testari*, in like manner as *juramentum*, *incrementum*, and others, from other verbs. The definition of the old Roman lawyers is much better than their etymology: "voluntatis nostræ justa sententia de eo, quod quis post mortem suam fieri velit;" which may be thus rendered into English: "the legal declaration of a man's intentions, which he wills to be performed after his death." It is called *sententia*, to denote the circumspection and prudence with which it is supposed to be made; it is "voluntatis nostræ sententia," because its efficacy depends on its declaring the testator's intention, whence in English it is emphatically styled his *will;* it is *justa sententia*, that is, drawn, attested, and published, with all due solemnities and forms of law; it is "de eo, quod quis post mortem suam fieri velit," because a testament is of no force till after the death of the testator. Testaments are divided into two kinds; written, and verbal or nuncupative; of which the former is committed to writing; the latter depends merely upon oral evidence, being declared by the testator *in extremis*, before a sufficient number of witnesses, and afterwards reduced to writing.

TESTUDO, in the military art of the ancients, was a kind of cover or screen which the soldiers formed with their bucklers, by holding them up over their heads, and standing close to each other. This expedient served to shelter them from darts and other missiles, especially those thrown from above, when they went to the assault. The same name was also applied to a large wooden tower which moved on several wheels, and was covered with bullock-hides, serving to shelter the soldiers when they approached the walls to mine them, or to batter them with rams. It was called *testudo*, from the strength of its roof, which covered the workmen as the shell does the tortoise.

TETBURY, a town of the hundred of Longtrees and county of Gloucester, ninety-nine miles from London. It is on an elevated spot on the borders of Wiltshire. There are manufactures of woollen cloths. It is moderately well built, and has a good market-house well attended. The inhabitants amounted in 1821 to 2734, and in 1831 to 2939.

TETHUROA, a small island in the South Pacific Ocean, subject to Otaheite, twenty-four miles north-west of Point Venus. Long. 149. 30. W. Lat. 17. 4. S.

TETRACHORD (*τετράχορδον*), a group of four sounds in melodic succession, and belonging to the ancient Greek system of music.

TETRARCH, a prince who holds and governs a fourth part of a kingdom. Such originally was the import of the title *tetrarch;* but it was afterwards applied to any petty king or sovereign, and became synonymous with ethnarch, as appears from the following considerations. Pliny makes mention of six tetrarchies within the city of Decapolis; Herod's kingdom was only divided into three parts, which yet were called *tetrarchies*, and the sovereigns, Luke iii. 1, *tetrarchs;* Josephus tells us, that, after the battle of Philippi, Antony, going into Syria, constituted Herod *tetrarch;* and on medals the same Herod is called *ethnarch*.

TETRASTYLE, in ancient architecture, a building, and particularly a temple, with four columns in its front.

TETTUA MOTU, a cape on the east coast of New Zealand, on the north-east point of Poverty Bay. Long. 181. 30. W. Lat. 38. 36. N.

TEUTONES, or TEUTONI, a people always by historians joined with the Cimbri; both seated, according to Mela, beyond the Elbe, on the Sinus Codanus, or Baltic; and there, it is supposed, lay the country of the Teutones, now *Ditmarsh;* diversity of dialects producing the different terms *Teu, Tut, Dit, Tid*, and *Thod*, which in the ancient German language signified *people.* Of these Teutones, Virgil is to be understood in the epithet *Teutonicus;* an appellation which more lately came to be applied to the Germans in general, and later still the appellation *Alemanni.* The Teutones, in conjunction with the Cimbri and Ambrones, made war on the Romans, and marched towards Italy in the year 101 B. C. We are told, that the Teutones alone were so numerous, that they were six whole days without intermission in passing the Roman camp. In transalpine Gaul they engaged the consul Marius, but were defeated with incredible slaughter; 100,000 of them, according to the lowest calculations, being killed on the spot. According to others, the number of those killed and taken prisoners amounted to 290,000.

TEUTONIC, something belonging to the Teutones. The Teutonic language is supposed to have been the language of the ancient Germans, and hence is reckoned among the mother-tongues.

TEUTONIC *Order*, an order of military knights, established towards the close of the twelfth century, on the following occasion. When the emperor Barbarossa engaged in a crusade for the recovery of the Holy Land out of the hands of Saladin, he was followed by great numbers of German volunteers, who from various motives enlisted under his banners. After the emperor's death, the Germans, who had signalized themselves before Acre or Ptolemais, resolved to choose another leader; and at last fixed their choice upon Frederick duke of Suabia, second son to the emperor, and Henry duke of Brabant. Under these generals they behaved with so much bravery, that Henry king of Jerusalem, the patriarch, and several other princes, determined to reward their valour by instituting an order of knighthood in their favour. This was accordingly done, and the new knights had at first the title of the knights of St George; afterwards it was thought proper to place them under the tutelage of the Virgin Mary, to whom there was already an hospital dedicated on Mount Zion, for the relief of German pilgrims. From this time they were called *Equites Mariani*, or knights of St Mary. Laws, regulations, and statutes, were drawn up for them by the Christian kings in Syria and the patriarch; and, among other obligations, it was required, that every person admitted to the privileges of the order should be of noble parentage; that the order should defend the Christian religion and the Holy Land; that they should exercise hospitality towards the Christians in general, but particularly those of their own country; and that they should with all their power endeavour to propagate and extend the Christian faith. In the year 1190, having become rich by donations from the superstitious, they elected as their first grandmaster Henry Walpot, a German, who had distinguished himself by his zeal and valour; and their choice was confirmed by the emperor. The following year, Pope Celestine III. confirmed their privileges already granted, giving them the title of the Teutonic knights of the Hospital of St Mary the Virgin. By the conditions of this bull, they vowed perpetual continence, obedience, and poverty; obligations to which it may well be imagined they did not very strictly adhere.

TEWKESBURY, a town of the hundred of the same name, in the county of Gloucester, 104 miles from London. It stands on the banks of the river Severn, near to the junction of the Avon with that stream. It is finely situated on a rising ground, and for the most part is well built. The church is a Gothic structure, one of the finest and largest in England, and formerly occupied by a mitred abbot. It is 300 feet in length and 120 feet broad; the chancel has several painted windows, and many fine monuments. There is a brisk trade carried on by both rivers, and in the town there are small manufactures. It is an ancient borough, and is governed by a mayor, four aldermen, and eleven councillors, and returns two members to parliament. There are good markets on Wednesday and Saturday. Near this place was fought the great battle between the Yorkists and the Lancastrians in 1471, when the former became the conquerors. The inhabitants amounted in 1821 to 4962, and in 1831 to 5780.

TEXEL, an island on the northern shore of the province of North Holland, separated from the mainland by the channel of Marsdiep, which is an entrance to the Zuyder Sea. It is about twelve miles long and three broad, and contains six villages, with 4950 inhabitants, who have flocks of 30,000 sheep yielding the finest wool. Near to it Admiral Blake, in 1653, gained a victory over Van Tromp; and another battle was fought in 1673 with the combined fleets of England and France against the Dutch, when the victory was doubtful. At this place, too, in 1799, a squadron of Dutch ships of war in a state of insubordination was surrendered to the British. There are fortifications on the island, commanding the anchorage.

TEXT, a relative term, contradistinguished from gloss or commentary, and signifying an original discourse exclusive of any note or interpretation. This word is particularly used for a certain passage of Scripture, chosen by a preacher as the subject of his sermon.

TEXTURE properly denotes the arrangement and cohesion of several slender bodies or threads interwoven or entangled among each other, as in the webs of spiders, or in cloths.

THALES, a celebrated Greek philosopher, and the first of the seven wise men of Greece, was born at Miletus about 640 B. C. In order to improve himself in the knowledge of the sciences, he travelled into Egypt, where he discoursed with the priests and other learned men. Some say that he married; but others observe that he eluded the solicitations of his mother on this head, by telling her when he was young that it was too soon, and afterwards that it was too late. Thales acquired great reputation by his wisdom and learning: he was the first among the Greeks who foretold eclipses of the sun, and made extraordinary discoveries in astronomy. He was the founder of the Ionian sect of philosophers, who were so denominated from his being born in Ionia. He maintained that water was the principle of which all the bodies in the universe are composed; that the world was the work of God; and that God sees the most secret thoughts of the heart. Among his wise maxims, the following have been recorded. The most difficult thing in the world is to know ourselves, the most easy to advise others, and the most sweet to accomplish our desires. In order to live well, we ought to abstain from what we find fault with in others. Bodily felicity consists in health, and that of the mind in knowledge. The most ancient of beings is God, because he is uncreated: nothing is more beautiful than the world, because it is the work of God; nothing more extensive than space, quicker than spirit, stronger than necessity, wiser than time. It was also one of his sentences, "that we ought never to say that to any one which may be turned to our prejudice; and that we should live with our friends as with persons that may become our enemies." He thanked God for three things; that he was born of the human, not of the brute species; a man, and not a woman; a Greek, and not a barbarian. None of the ancient philosophers ever applied himself more earnestly to the study of astronomy than Thales. Diogenes Laertius reports, that leaving his lodging with an old woman to contemplate the stars, he fell into a ditch; on which the good woman cried, "How canst thou know what is doing in the heavens, when thou canst not perceive what is at thy feet?" He went to see Crœsus, who was marching with a powerful army into Cappadocia, and enabled him to pass the river Halys without making a bridge. Thales died soon afterwards, at the age of about ninety. He composed several treatises in verse, on meteors, the equinoxes, &c. but they are all lost.

THALIA, in Pagan mythology, one of the nine Muses. She presided over comedy; and is represented crowned with a garland of ivy, holding a mask in her hand, and wearing buskins on her feet.

THAME, a town of the hundred of the same name, in the county of Oxford, forty-six miles from London. It stands on a rising ground on the banks of the Thames, consists of one long street, and has a fine Gothic church, a free school, and alms-houses. The river is navigable to the town. There is a market on Tuesday. The inhabitants amounted in 1821 to 2479, and in 1831 to 2885.

THAMES, a river of England. As this river passes through the metropolis, the reader will find, under the article London, a description of the most important circumstances relating to it in that part of its progress which is under the superintendence of the magistracy of London. Without entering into the disputes as to the origin of the river, which are prolix, and give no definite result, we take it up, where several of the streams meet, at Lechlade, where it first becomes navigable to London, at a distance by water of 138 miles. It passes by Bampton on its left to Oxford, bearing the name of the Isis, which it there loses, and adopts that of a smaller stream coming from Thame, and assumes the name of that place. It receives the water of the Windrush and the Evenlode above Oxford, and that of the Charwell as it leaves the city. It then proceeds to Abingdon and Dorchester, and enters the county of Berks at Wallingford, and in its course is augmented by small streams. From Wallingford it proceeds to Reading, where the Kennet joins its copious stream. It then washes the towns of Henley, Marlow, Maidenhead, Windsor, and Eton, and forms the boundary between the counties of Buckingham and Berks. At Colnbrook it receives the waters of the Coln, and soon becomes the boundary between the counties of Surrey and Middlesex, in which latter county, just above the bridge, is the London stone marking the boundary of the city's jurisdiction. It afterwards has its body of water augmented by the streams of the Wey, the Wandle, the Lea, the Roding, the Darent, and the Medway, when it is lost in the great estuary at the Nore.

Thames, a river of New Zealand, which, about fourteen miles from its entrance, is as wide as the Thames at Greenwich. The course is from south to north.

THANASIR, or Tannesar, a town of Hindustan, province of Delhi, which formerly contained the celebrated temple of Jug Soom, which was held in the highest estimation by the Hindus, and innumerable pilgrims flocked to it from all parts of India. It now belongs to the Sikhs, and is principally inhabited by that race and by Hindus. Long. 76. 48. E. Lat. 29. 55. N.

THANE, or Thanus, a name given to the nobility in Britain before the time of William the Conqueror. It signifies a minister or honourable retainer, from the verb *thenian*, to minister. There were several degrees of nobility among the Anglo-Saxons; but those most commonly mentioned are the king's thanes and the alderman's thanes. The king's thanes seem to have been of three different degrees, according to their different degrees of wealth or favour at court. The alderman's thanes seem to have been of the lowest degree of nobility, and next to them those who were promoted to that dignity from their advancement in the church, from their valour, success in agriculture, or commerce; for if a ceorl or farmer applied to learning, and attained to priest's orders; if he acquitted himself so well as to obtain from a nobleman five hythes of land, or a gilt sword, helmet, and breast-plate, the reward of his valour; or if by his industry he had acquired the property of five hythes of land; or if he applied to trade, and made three voyages beyond sea in a ship of his own, and a cargo belonging to himself, he was denominated a *thane*.

The thanes, who were the only nobility among the Anglo-Saxons, were a very numerous body of men, comprehending all the considerable landholders in England, and filling up that space in society between the ceorls or yeomanry on the one hand, and the royal family on the other; a space which is now occupied both by the nobility and gentry. In times of war, they constituted the flower of the armies, and in times of peace they swelled the trains of the kings, and added greatly to the splendour of their courts, especially at the three great festivals of Christmas, Easter, and Whitsuntide. From this body all the chief officers, both civil and military, as aldermen, greeves, earls, heretogens, &c. were taken; and to obtain some of these offices was the great object of their ambition. Before they obtained an office, their lands were their only support; and they lived in greater or less affluence, according to the extent of their estates. These they divided into two parts; one of which they called their *inlands*, and the other their *outlands*. Their inlands they kept in their own immediate possession, and cultivated them by the hands of their slaves and villains, in order to raise provisions for their families; their outlands they granted to ceorls or farmers, either for one year, or for a term of years, for which they received a certain stipulated proportion of their produce annually. These customs had long prevailed among their ancestors in Germany, and were adhered to by their posterity in England till the conquest. The thanes were under no obligations on account of their lands, except the three following, which were indispensably necessary to the defence and improvement of their country; to attend the king with their followers in military expeditions, to assist in building and defending the royal castles, and in keeping the bridges and highways in proper repair. To these obligations all proprietors of land (even the churchmen for a long time not excepted) were subjected; and these services were considered as due to their country, rather than to the persons of their kings, and were agreed to by all as being necessary to their own preservation and convenience. This title of thane was abolished in England at the conquest.

THANET, or Isle of Thanet, a part of the county of Kent, in the north corner of it, surrounded by the sea, except at one part, where the river Stour, which was once a large estuary, divides it from the rest of the county. It extends nine miles from east to west, and eight miles from north to south, and contains 24,880 acres of fertile land, with a population in 1831 of 26,090 persons. It comprises eight parishes, and three other divisions called Villa. Within it are the towns of Margate, Ramsgate, and Broadstairs, which have rapidly increased in extent, in the number of good houses, as well as in inhabitants; and from the number of persons who resort to them for the purpose of sea-bathing, a continued increase may with certainty be anticipated. The soil of the island is remarkably fertile, and is perhaps better cultivated than any other district of the same extent in England. Besides the corn consumed at home, it is enabled to supply the city of London with 30,000 quarters annually, which is forwarded by means of water-carriage. The wheat and barley sent from hence is com-

Th n
Thea nes.

sidered among the best brought to the London market. Here many kinds of seeds are produced for the seedsmen of the metropolis; not only the seeds of clover, lucerne, sainfoin, and trefoil, but also of canary, anis, radish, spinach, cabbage, and mustard. About 4000 acres are valuable pasture, and used for the fattening of sheep and cattle. Except in the towns, there are no gentlemen's seats in the island, most of them having been converted into farmhouses, and occupied by the holders of large farms. The people on the shore are for the most part occupied in maritime affairs, especially in assisting ships in distress, in which they display great boldness, skill, and activity.

THANN, a city of France, in the department of the Upper Rhine, and the arrondissement of Befort. It is situated at the foot of a mountain, upon which the castle of Engelburg stands, on the river Thuron, and at the entrance of the valley of St Martin. The church of St Theobald is a curious object, on the model of the cathedral of Strasburg, with a tower 300 feet in height. In 1836, Thann contained 3937 inhabitants, mostly using the German language, and employed in making cotton goods, hosiery, and leather, and in working some mines of coal in the neighbourhood.

THASO, or Tasso, an island on the northern coast of Greece, the Thasos of antiquity. It stands in the Gulf of Contessa, about four miles from the mainland, and seven leagues to the eastward of Cape Karca or Kofani. It is thirteen miles long from north to south, and eleven broad from east to west. It is mountainous, particularly in the south and in the east parts, but affords excellent wine, with a quantity of honey and bees' wax. The gold mines mentioned by ancient writers are not now known to exist, but it still supplies some fine marbles. In former times it was celebrated for its fertility, but of late years it has been much neglected. On the shore of the mainland, opposite to Thaso, is the town of Cavalla, before which is good anchorage in from eight to ten fathoms water, under the protection of a castle. On the north-east side there is a good roadstead, near the town of Tasso Paolo. The centre of the island is in long. 24. 39. E. and lat. 40. 41. N.

THATCHAM, a town of England, in the hundred of Reading and county of Berks. It stands on the great road from London to Bath and Bristol, being fifty-three miles from the former city. It is well built, and was formerly a place of some consequence. It has a parish church and an endowed school. The parish is very extensive, containing 1149 acres of well-cultivated and productive land. The chief trade is attending on the numerous travellers that pass through. Within the parish there are two hamlets, Greenham and Midgham. In 1821 the whole population amounted to 3677, and in 1831 to 3912.

THAXTED, a town of the hundred of Dunmow, in the county of Essex, forty-seven miles from London. It is a place of little trade, though formerly much cutlery was made there. It has a spacious church, built by John duke of Lancaster, and several chapels for dissenters. It was formerly a borough, and more considerable than it is at present. There is a market on Friday. The inhabitants amounted in 1821 to 2045, and in 1831 to 2293.

THEATINES, a religious order in the Romish church, so called from their principal founder John Peter Caraffa, then bishop of Theate, or Chieti, in the kingdom of Naples, and afterwards pope, under the name of Paul IV. The names of the other founders were Gaetan, Boniface, and Consiglieri. These four individuals, desiring to reform the ecclesiastical state, laid the foundation of an order of regular clerks at Rome in the year 1524. Pope Clement VII. approved the institution, and permitted the brethren to make the three religious vows, to elect a superior every three years, and to draw up statutes for the regulation of the order. They were the first who endeavoured, by their example, to revive among the clergy the poverty of the apostles and first disciples of our Saviour, and were also the first who assumed the title of *regular clerks*.

Theatre.

THEATRE, a place in which dramatic pieces are exhibited. The article Drama, besides relating the literary history of the stage, has furnished as minute an account of the plan and arrangements of the ancient theatres as the purposes of this work allow. Similar details as to the modern theatres of the Continent, would lead into a field far too wide to be traversed; and we must here confine ourselves to a brief notice of the establishments devoted to dramatic entertainments in Britain.

The earliest positive mention of professional actors in England, as a class distinctly separable from minstrels or others, occurs about the middle of the fifteenth century; and a sumptuary law of Edward IV., passed in 1464, makes an exception in favour of "players in their enterludes." Richard III., when duke of Gloucester, kept a company of players and musicians in his pay. The children of the king's chapel were trained for acting as well as singing; and Henry VII. had two distinct sets of players, the one being composed of the gentlemen of the chapel, who performed regularly at certain seasons; and the other, the "players of interludes," being more like those strolling companies whom about that time we find to have been often taken into the pay of noblemen throughout the country. In the reign of Henry VIII. the court amusements became more expensive and diversified, in this respect as in every other; and the royal example was eagerly imitated by the wealthy nobles. Besides the annual payments from the king to the Lord of Misrule, and the large sums expended on masques and other entertainments, we find salaries to have been regularly paid to two companies of the "king's players," in addition to the children of the chapel; and the royal players, as well as those of the nobility, travelled through all the provinces. In 1528, Henry entertained the French ambassadors at Greenwich with a Latin moral play, acted by the pupils of St Paul's school, in which the reformation was ridiculed, and Luther and his wife were prominent characters. The corporations, especially that of Chester, so celebrated for its patronage of religious theatricals, continued to exhibit dramatic shows on occasions of festivity; although the corporation of London appear, even before the middle of the sixteenth century, as decidedly opposing stage plays, and attempting to suppress them within their jurisdiction. In 1543 was passed the earliest act of parliament for the regulation of the stage; and in 1546, if not earlier, was established the office of Master of the Revels, for managing and superintending the pastimes of the court. The disturbances of the two short reigns which succeeded Henry's, checked the progress of theatrical amusements; but their prosperity revived on the accession of Elizabeth, who lived to witness the rise of the dramatic art to its highest literary excellence. The companies of itinerant players multiplied so excessively, and their irregularities were considered so dangerous, that a statute of the queen, passed in 1572, stamped the first public brand on the profession; declaring that all players, fencers, bearwards, not belonging to any nobleman,—and all tinkers, jugglers, pedlars, &c. not having license from two justices of the peace,—should be dealt with as rogues and vagabonds.

About the year 1570, or very little later, were erected the earliest buildings in London that were devoted exclusively to theatrical representation. These were two, both in Shoreditch; the one called "The Theatre," by way of eminence, the other called "The Curtain." A third theatre, within the privileged precinct of the Blackfriars, was built in 1576, by Burbadge, the father of the famous player, whose company had been driven out of the city by the corporation; and the Globe on the Bankside in Southwark (which afterwards became the summer theatre of Shakspeare's company, while the Blackfriars was their place of acting in winter) was erected about the year 1594. But between 1570 and 1600, there arose eleven buildings, if not more, in or about London, applied to the purpose of dramatic exhibitions. Several of these were always obscure, but others possess interest, on account of the merit of the works produced on their stages. The Globe and Blackfriars always maintained the first rank, and continued in the possession of the company called the Queen's Players; Paris-Garden, an old building, was used both for stage-playing and bear-baiting; and the Rose, built about 1585, and the Fortune, in 1599, were especially under the control of the pawnbroker Philip Henslowe, whose manuscript diary is one of the most instructive documents which we possess relating to the dramatic history of that age. An attempt of the government in 1598 to limit the license of playing in London to two companies, bearing the names of the Lord Chamberlain and Lord Admiral, seems to have been completely unsuccessful. In the reign of James, the Globe and Fortune were successively burnt, but both rebuilt; and no new theatre of consequence was erected except the Phœnix or Cockpit in Drury Lane, and the Red Bull in Saint John Street, if indeed the latter was not somewhat older.

In the same reign the principal companies of players were three. Those who obtained the royal patent of 1603, at the head of whom stood Shakspeare, Burbadge, and Laurence Fletcher, had been recently called the Lord Chamberlain's men, but now resumed their older title of the King's Players or Servants. The company at first named Players of the Lord Admiral (or of the Earl of Nottingham, who held that office) were afterwards called the Players of Prince Henry: these were the actors especially connected with Henslowe; and his celebrated son-in-law Edward Alleyn, the founder of Dulwich College, was the most distinguished among them. Those actors who had formerly been called Children of the Chapel, but of whom many were persons of mature age, were now called Children of the Revels, and appear frequently in connection with Ben Jonson's works.

James had passed an act against profanity in plays: his son passed one, the first of his reign, against the acting of them on Sundays, an impropriety which it had been formerly attempted to remove, and which the growing spirit of puritanism regarded with increasing horror. But Charles, whose taste for literature and art was the best feature in his character, was a liberal and judicious patron of the theatre during those few early years of his reign that preceded the disturbances. In the same year as the act last named (1625), he renewed his father's patent to the "King's Players," in favour of Heminge and Condell, Shakspeare's executors, and others; annexing a condition which we find often insisted on in regard to dramatic exhibitions in those days, that no performance should take place in London unless the persons infected by the plague fell short of a certain number in the week. About 1635 there were in the metropolis, besides a French troop and a Spanish, five settled companies of English players;—the King's Servants, under Lowin and Taylor, who played, as of old, at the Globe and Blackfriars;—the Queen's, who played at the Cockpit;—the Prince's men, at the Fortune;—the Children of the Revels, probably at the Red Bull;—and the company attached to a new theatre in Salisbury Court. The civil war broke out in 1642; and in September of that year an "ordinance of both houses of parliament," setting forth the necessity of fasting and prayer, and of all other means "to appease and avert the wrath of God appearing in these judgments," ordained that, "while these sad causes and set times of humiliation do continue, public stage-plays shall cease and be forborne." In 1647 a more peremptory act declared stage-players punishable by public whipping for the first offence, and authorized the demolition of the theatres. And for nearly ten years from that time we hear of only one or two unimportant infractions of the prohibition.

During those early ages of our dramatic annals, which the civil wars thus brought to a close, the theatres were divided into two classes, the Public and the Private, the distinctions of which are not yet very clear, and do not seem to have been ever very important. The private theatres, it is said by Mr Collier, were smaller than the others, and were entirely roofed over, which the latter were not; the performances in them were by artificial light; their "pits" had seats; and there were other minor differences of arrangement. The Blackfriars, the Cockpit, and the house in Salisbury Court, were private theatres; the Globe, Fortune, and Bull, were public. There has been loud controversy on the question whether moveable scenery was at all used in the time of Shakspeare; but it may be considered as having been authoritatively settled in the negative. There was a balcony or upper stage, which served, on multifarious occasions, the purposes of a second scene, representing the walls of a town in King John and elsewhere,—Juliet's balcony,—or the seat of the audience at the performance of the play in Hamlet, in which the player-king and queen occupied the front of the main stage. Besides the curtain which concealed this balcony when it was not required, other curtains, called traverses, crossing the back of the stage, served to separate a portion, which, by drawing these partly or wholly, could be made to pass for an inner room. There is good evidence of the use of trap-doors in the stage; and descents from above were also attempted, as in Greene's Alphonsus, a play older than most of Shakspeare's, in which one direction was this—"let Venus be let down from the top of the stage;" and another, in the same play, orders that Venus shall either simply make her exit, "or, if you can conveniently, let a chair come down from the top of the stage and draw her up." The performances, in Shakspeare's time, took place but once a day; the usual hour seems to have been three o'clock; and nothing except the short and rude pieces called jigs seems to have been exhibited besides the principal play. There were play-bills pasted up in the streets as early at least as the middle of the sixteenth century; and in 1620 a royal patent was granted for the printing of them. The purchases which theatrical companies made from authors seem to have been understood as comprehending, not merely the right of representing the pieces, but the entire copyright; and the care of the players to keep popular pieces in manuscript was one of the causes especially destructive to the dramatic literature of those times. Before the year 1600, Henslowe, whose loans had made most of the dramatists of the time his bond-slaves, seems never to have paid an author more than eight pounds for a play; and even authors of reputation, such as Dekker, sometimes received much less. But the value of literary labour rose in the beginning of the next century, and we then find even inferior writers, like Daborne, stipulating for sums as high as twenty pounds. The usual price, however, till the closing of the theatres, was about twelve pounds, to which were sometimes added the receipts, in whole or in part, of one of the early performances. The actors were divided into two classes: the Shareholders, who were joint proprietors of the establishment, and ranked according to the amount of their interest, as whole sharers, three-quarter sharers, or half sharers; and the Hired Men, who were the inferior actors, receiving weekly salaries from the sharers. In 1608, when the corporation contemplated removing the players of the Blackfriars, but proposed giving them compensation for the loss of their property and employment, a statement was produced which gives some curious results. It appears that the whole interest in the profits of the establishment was divided into twenty shares, which belonged to eleven actors. Burbadge owned the building and four of the shares; Shakspeare owned four shares, with the wardrobe and properties; Fletcher had three shares; Heminge and Condell two shares each; Taylor and Lowin a share and half each; and four others parted the remaining two shares equally among them. Each share was valued at L.33. 6s. 8d. per annum, and was offered to the corporation at seven years' purchase: the building was valued at L.1000, the wardrobe and properties at L.500. The whole property was thus estimated by the players themselves at L.6166. 13s. 4d., besides compensation demanded by the hired men, and allowances to the widows and orphans of deceased players. Shakspeare's interest was valued by him at L.1433. 6s. 8d., which might be equal to between L.6000 and L.7000 in modern money. All these valuations, however, must have been above the truth.[1]

The representation of Sir William Davenant's Siege of Rhodes, in 1656, was the first step towards a revival of theatrical amusements; and three years later, two rival companies began to act openly in London, the one at the Cockpit, the other at the Red Bull. The former, originally organized by one Rhodes, a bookseller, was composed chiefly of new actors, among whom the best, Betterton and Kynaston, were youths who had been his own apprentices; the latter embraced those old actors who had survived the wars, in which several of them had served with some distinction. Two royal patents (the origin of the modern monopoly) were issued in 1663. The one was in favour of Davenant, who placed himself at the head of Rhodes's players, and acted for some time at a new house in Lincoln's Inn Fields, calling his company the Duke of York's, though they were sworn in as servants of the king. The other patent was given to the witty Killigrew, whose actors, called the King's Company, were those who had begun to play at the Red Bull, but who were removed to a new theatre built in Drury Lane. The new companies presented one remarkable novelty, in the accession of several females to their number. Before the Restoration, the female parts had been performed by the younger male actors; and the only instance in which an innovation had been tried was in 1629, when a French company appeared at the Blackfriars, consisting partly of women, or, as Prynne is pleased to express it, "monsters rather"—"an impudent, shameful, unwomanish, graceless, if not more than meretricious attempt." Those who looked on the matter in a more candid and philosophical temper, might not unreasonably have expected that the introduction of actresses to the stage would have helped to purify it from that coarseness which had disfigured the drama in its preceding ages. But after the Restoration, the players, the public at large, and the court, which gave law to the public and the players, were all alike corrupt; and if the new addition did nothing to deteriorate, it did at all events nothing to retard the increasing degradation. That which, in most of the dramas produced in Elizabeth's reign, had been merely coarseness of language, had been accompanied in very many of the later plays with real licentiousness of principle and feeling; and the profligacy of Charles the Second and his minions was now aped with applause in works full of the most disgusting and disgraceful obscenity. The injury which morality received from the stage was accompanied by injury to taste, inflicted not only by that undramatic spirit which pervaded the very best works of the time, but by the pomp of decoration, the singing, music, and dancing, by which Davenant sought to make his theatre a match for the superior histrionic skill displayed by his rivals. The licentiousness was greatly amended after the Revolution, but the corruption of taste gave way much more slowly.

In 1671 the Duke's players opened a new theatre in Dorset Gardens, probably on the site of the old house in Salisbury Court; and in 1674 the King's players opened a second new theatre in Drury Lane, in the place of their former one, which had been burned down. A union of the two patents, and of both companies, produced discontents both among the actors and the public; and a new patent having been granted by King William to Betterton and some of the rebellious players, a third theatre was built by them in Lincoln's Inn Fields, for which was afterwards substituted a splendid but ill-designed house in the Haymarket, planned by Sir John Vanbrugh, and opened in 1705. In the mean time, various disputes and misfortunes happened among the old patentees. The interference of the Lord Chamberlain, whom, as coming in the place of the Master of the Revels, the actors and the public sometimes considered as having exclusive jurisdiction over the playhouses, while at other times the managers voluntarily submitted their disputes to his arbitration, was repeatedly exerted, and often very arbitrarily, to restore something like order and prosperity; and at length matters were placed for a time on a footing not materially different from the modern one. The theatre in the Haymarket was appropriated solely to the opera; and the two old patents of Charles the Second were the warrant under which the regular drama was played at Drury Lane by a company acting under Killigrew's patent, and at the theatre in Lincoln's Inn Fields (once more rebuilt) by a company directed by the younger Rich, the holder of the patent which had been granted to Davenant. At Drury Lane, plays which, however indifferent, were the best the age could produce, or the public endure, were acted with excellent skill by a company directed by the first actors of the day, Wilks, Dogget, Booth, and Cibber, with whom, for a good many years, Sir Richard Steele was associated in the patent. At Lincoln's Inn Fields were produced those execrable abortions called pantomimes, on which the manager Rich prided himself so much, and whose scenery and drolleries gained for his house a popularity which he probably thought cheaply purchased by the ridicule showered on him without ceasing by the wits of Queen Anne's reign.

In 1720 there arose new quarrels, new financial embarrassments, and new interferences and prohibitions by the Lord Chamberlain; but of the events which took place for many years, two or three only demand notice. The first was the opening, in 1729, of a new theatre in Goodman's Fields, rebuilt in 1732, which did not for some time obtain such success as to tempt the patentees to suppress it. A second occurrence was the transfer of Rich's company, in 1733, to a new house in Covent Garden. In 1737 there was passed, in spite of energetic and well-founded opposition, an act of parliament, taking from the crown the right of granting any new patents for theatres in the metropolis, and forbidding the representation of any plays not previously licensed by the Lord Chamberlain. In 1741 Garrick appeared at Goodman's Fields, in the character of Richard the Third.

In 1747 the patent of Drury Lane was renewed in favour of Lacey, who was to be the man of business of the establishment, and Garrick, who was to support it both as actor and author. Under the direction of these managers the theatre enjoyed uninterrupted prosperity for nineteen years; and, however faulty Garrick's ideas of the literary qualities of the drama may in some respects have been, we owe him a heavy debt of gratitude for the benefits he conferred on public taste by his restoration of Shakspeare's works to that place on the stage from which they had been banished with equal constancy by the debauchery of Charles the Second's time, and the pedantic coldness of Queen Anne's. In the mean time, after the death of Rich in 1761, Covent Garden was chiefly supported by its musical pieces; and the new management, begun in 1767, at the head of which stood the elder Colman, produced little advantage to any except the lawyers who received fees in the lawsuits between the proprietors. In 1766, a theatre in the Haymarket, not that which held the patent, but another which had been built in 1720, and which had received occasional licenses for performances during the summer, received a regular patent, granted in favour of Foote, which recognized its actors as the king's servants, and allowed performances in it from the 14th of May to the 14th of September. The patentee immediately pulled down the old house, and built a new one, which was opened in 1767.

---

[1] For the history of the theatres till their suppression in the civil wars, see Collier's Annals of the Stage, 3 vols. 1831; and Malone's History of the Stage, in his posthumous Shakspeare of 1821.

In 1790 there was built, on the site of Sir John Vanbrugh's Haymarket Theatre, a new house devoted to the Italian opera, which received the name of the King's Theatre, and has since then suffered no very material alteration in the general structure of its interior. In 1794 was opened a new theatre in Drury Lane, built, after a plan by Holland, on the site of the former one; and two or three years earlier, Covent Garden had received such improvements as amounted nearly to a total renovation. Long before these events, however, the management of Covent Garden had passed to Harris; while at Drury Lane, Garrick had been succeeded by Sheridan, Ford, and Linley; and Foote's place at the Haymarket had been filled by Colman. In 1803 the stage-management of Covent Garden passed to John Philip Kemble; and the subsequent changes which took place for some time in that and the other theatres are not of such literary moment as to require notice. In September 1808, Covent Garden Theatre was burnt to the ground; and the present building, erected on its site, after a plan by Smirke, was opened within twelve months from the catastrophe. In 1809 a similar calamity destroyed the theatre in Drury Lane, which was rebuilt by Wyatt, and opened for performances in 1811. Foote's summer theatre in the Haymarket made way, in 1821, for a new house planned by Nash, and possessing a patent extending its performances to seven months.

It would not be too much to say, that the excellence of the dramas which our modern stage has produced, bears, in comparison with those of our older times, a proportion nearly inverse to that of the dimensions and adornment of the edifices in which the works of the two ages have been respectively acted. The question as to the causes of our decay, and as to our probable prospect of revival, has been handled elsewhere, and would lead us beyond the proper province of this article; but the discouraging state of the drama during the whole period which has elapsed in the present century may be admitted as a sufficient reason for declining to trace the history of our great theatres through that series of misfortunes which has hung over all of them, especially Drury Lane, for the last thirty years. The ruinous consequences of their injurious monopoly have not, it should appear, been even yet made sufficiently obvious to those who possess the power of remedying the evil; and the many minor theatres, which, if allowed free scope, might perhaps become the nurseries of a new school in dramatic art, are left to struggle against obstacles arising from this cause, and seconded but too faithfully by the general corruption of dramatic taste.

The evils produced by the monopoly of the great theatres in the metropolis were till lately aggravated tenfold by the laws affecting copyright in dramatic performances. Literary property of this sort was continually invaded, and towards the end of the eighteenth century the courts of law formally authorized the encroachments. The decisions were founded on very curious and subtile distinctions.

The first case brought forward was that in which Macklin, in 1770, applied to the Court of Chancery for an injunction to stay the printing of his farce of "Love-a-la-Mode" in a magazine, in which it was appearing piecemeal. The farce had never yet been printed or published; and the booksellers obtained their manuscript from a shorthand writer, whom they employed to attend the theatre and take down the dialogue from the mouths of the actors. The court held that this was a *publication* of the play, and forbidden by the act of Queen Anne. In terms of this decision, it was always afterwards held, that the author or his assignee retained the exclusive right of *printing* and *publishing* a play, although it might have been already acted.

But in 1790, the Court of King's Bench laid down the law very differently for the case in which redress is claimed against the unauthorized *representation* of a play on the *stage*. O'Keeffe's farce, "The Agreeable Surprise," had been acted on various stages, although the copyright had been sold by the author to Colman of the Haymarket. Colman prosecuted the manager of the Richmond theatre for infringement of the act of Queen Anne, maintaining that his acting of the piece was a publication of it in the sense of the statute. The court found that acting (or, as one of the judges called it, repeating a book from memory) was *not publication*, nor prohibited by the act. The provincial managers thenceforth continued to plunder dramatic authors with impunity, as soon as, by the publication of their works, or in other ways, they were able to procure access to them. No endeavour was made in the courts to shake the decision given in Colman's case, till the year 1822, when Murray the bookseller prosecuted Elliston for acting Byron's tragedy of Marino Faliero, "altered and abridged for the stage," the play having been previously printed and published by Murray, the proprietor of the copyright. The attempt in this case to found the action for redress independently of the statute, was equally unsuccessful with the previous attempt to rest it solely on the statutory words.

These decisions, it is true, left several very important questions still undetermined; but the letter of the law, and the spirit of the interpretations which had been long put upon it, were equally unfavourable to the dramatic author. Writers of plays continued to depend for remuneration on the small sums which they could obtain from booksellers for the right of printing and publishing, with any other sum which the managers of the London theatres chose to give for the privilege of acting the drama till publication.

This unfair state of things was altered in 1833 by Sir Edward Lytton Bulwer's act, "To amend the laws relating to dramatic literary property." By this statute it is enacted, first, that the author of every dramatic piece *not* printed or published (or the assignee of the author) shall have, as his own property, the sole liberty of representing it, or causing it to be represented, at any place of dramatic entertainment; secondly, that the author of every dramatic piece which has been or shall be printed and published (or the assignee of the author) shall have, as his own property, the same liberty of representing it, or causing it to be represented, till the end of twenty-eight years from the date of the publication, and also during the residue of the author's life; thirdly, that the penalty for infringement of the act shall be, for each representation, an amount not less than forty shillings, or the full amount of the benefit or advantage arising from the representation, or the injury or loss sustained by the proprietor of the drama, recoverable in an action to be brought within twelve months after the offence. (B. L.)

THEBES, the name of a celebrated city of ancient Greece. It is supposed to have been built by Cadmus, about the year of the world 2555. This Cadmus, according to the Greeks, was the son of Agenor king of Sidon or of Tyre; but the Sidonians allow him to have been of no higher quality than his cook, and tell us that his wife was a musician at court, with whom he ran away into Greece. The Greek writers aver, that being commanded by his father to go in search of his daughter Europa, whom Jupiter in the shape of bull had carried off, and being forbidden to return

er of
Thebes.

without her, he built, or rebuilt, the city of Thebes, after having long sought her in vain. He was at first opposed by the Hyantes and Aones; the former of whom he defeated in battle, and forced to retire into Locris; the latter submitted, and were incorporated among his subjects.

Those who endeavour to extract some truth from the multitude of fables in which the early part of the Grecian history is obscured, are of opinion that Cadmus was one of the Canaanites expelled by Joshua; and that he was of the family of the Cadmonites mentioned by Moses and Joshua. He is allowed to have introduced the Phœnician letters into Greece, established the first schools, and introduced brass, which, from him, had the name of *Cadmean* given to it. The government of Thebes continued for a long time monarchical; and the names of a number of its kings have been transmitted to us, with some account of their transactions, though much obscured by fable.

Although the Thebans had been famed in the early period of their history for their martial achievements, yet in process of time they seem to have degenerated. At the time of the invasion of Xerxes, they were the first people in Greece who were gained over to the Persian interest. On account of this conduct, they became very obnoxious to the other states, especially to the Athenians, whose power and renown increased every day. The Thebans being in no condition to oppose such a formidable power, placed themselves under the protection of the Spartans, who, out of jealousy of the Athenians, readily forgave them; and so grateful were the Thebans for the kindness shown them at this time, that during the whole of the Peloponnesian war Sparta had not a more faithful ally. By these means they not only recovered the government of Bœotia, of which they had formerly been in possession, till deprived of it on account of their siding with the Persians, but their city became one of the first in Greece. By this prosperity the Thebans were so much elated, that, when the peace of Antalcidas came to be signed, they refused to agree to it, as they were thus once more deprived of the government of Bœotia; so that it was not without the utmost difficulty that they were overawed by the other states. Not content with forcing them to give up this point, however, the Spartans undertook to change the form of the Theban government, which at this time was a democracy, and accomplished their purpose, through the treachery of those who had the care of the citadel.

The Thebans continued under the power of the Spartans for four years; at the expiration of which, a conspiracy being formed against them by some of the principal people in the city, among whom was a young nobleman named Pelopidas, the Spartans were all massacred or driven out, and the citadel was regained. During the tumult Epaminondas, afterwards the celebrated general, with a number of the best citizens, joined the party of Pelopidas; and the latter having called a general assembly of the Thebans, proclaimed liberty to them, and exhorted them in the strongest manner to fight for their country. This speech was received with the greatest acclamations; Pelopidas was unanimously declared the preserver of Thebes, and was charged with the management of the war which was then to be undertaken against Sparta.

The Spartans defeated by Pelopidas.

These transactions so much exasperated the Spartans, that they immediately sent their king Cleombrotus against them, though it was then the depth of winter. The Athenians, in the mean time, who had hitherto assisted the Thebans, declined any further connection, lest they should draw upon themselves the resentment of the Spartans. But they were soon afterwards determined to act again on the same side, by an attempt which the Spartan general, Sphodnas, had rashly made on the Pyræus, or harbour of Athens. Thus, by means of the Athenians, a powerful diversion was made in favour of the Thebans, who gradually recovered all the towns of Bœotia, and at length began to act offensively against their enemies, and made a powerful invasion in Phocis. They had now many sharp encounters, which, though they did not amount to decisive battles, yet did not fail to raise their courage, and depress that of the Spartans. In these encounters Pelopidas always signalized himself; and in the battle of Tanagra, where the Lacedæmonians were entirely defeated by the Athenians and their allies, Pelopidas had a principal share in the victory, and killed the Spartan general with his own hand. Soon after this, with a body of only 300 Thebans, he entirely routed and dispersed nearly 1000 Spartans, which was the greatest disgrace that the latter had ever known; for till that crisis, whether in war with the Greeks or barbarians, they had never been overcome by an equal, much less by such an inferior number of troops.

Platæa and Thespia razed by the Thebans.

Account of Epaminondas.

His difference with Agesilaus king of Sparta.

These successes of the Thebans greatly alarmed the Athenians, who continually sought to oppose their growing power. In this opposition they were joined by the Platæans, who on that account became extremely obnoxious to the Thebans, so that they at last came to a resolution to surprise their city. This they accomplished, and entirely destroyed it, together with Thespia, another city extremely well affected to Athens. Encouraged by their success, the Thebans soon afterwards began to think of enlarging their territories, and of making encroachments on their neighbours, as they saw other states had done before them. This spirit of conquest is said to have been raised by their general Pelopidas. He was seconded by Epaminondas, a person who, though like him endowed with all the necessary qualities to make a complete captain or patriot, had till then preferred a private life, and lived in a constant course of virtue and the study of philosophy. He had as yet seldom appeared in public, except to get himself excused from those state employments which were so eagerly courted by others. This, however, had not hindered him from contracting an intimate friendship with Pelopidas, which had been daily improved by the correspondence of their tempers and principles, as well as by that zeal which both displayed for the good of their country. Before this period, they had often appeared together in action, and to such advantage, that Epaminondas's merit could no longer be concealed, nor indeed suffer him to continue longer in his beloved retirement. He at length found himself placed at the head of the Theban troops; where he gave such early proofs of his future prowess and abilities as justly secured him the next rank to Pelopidas. Both came now to be considered in the same light, as generals in the field, as governors at home, and as complete statesmen in the council. When the general treaty for restoring peace to Greece came to be proposed by the Athenians, and was upon the point of being executed by the rest of the states, the Thebans refused to agree to it, unless they were comprehended in it under the name of *Bœotians.* This demand was as strenuously opposed by the other contracting powers as insisted on by Epaminondas, who was there as ambassador on the part of the Thebans. Agesilaus, in particular, told him in plain terms that the Thebans ought to evacuate Bœotia, and leave the cities of it free and independent. He replied, that the Lacedæmonians would do well to set them the example, by restoring Messenia to its ancient proprietors, and Laconia to its ancient freedom; and that the pretensions of the city of Thebes to Bœotia were at least as well founded as those of Sparta to those two countries. He then proceeded to shew how far Sparta had aggrandized herself at the expense of her neighbours; that peace might be indeed obtained, and upon a solid and lasting footing; but that this could not be otherwise than by admitting the principle of equality. His bold though just remonstrance, in which not only Thebes, but Greece in general, was concerned, failed not to exasperate the haughty Spartan monarch; and the Athenians, who had till now looked upon the Thebans as dependants either on

The Spartans declare war against Thebes.

them or on the Macedonians, were not a little offended to hear their ambassador talk in such a high strain. The result of the conference was, that Agesilaus struck the name of Thebes out of the treaty, and declared war against them, about the year 371 B. C.

Are entirely defeated at Leuctra.

The Thebans were in no small consternation to see themselves engaged in a war with the powerful Spartans, without any ally to assist them; and the rest of the Grecian states having made peace with the latter, began to look upon the ruin of the former as unavoidable. They however resolved to make the best defence they could; and placed their army under the command of Epaminondas, assigning him, at his own request, six individuals to act as counsellors or assistants. The Theban army consisted at most of 6000 men, whereas that of the enemy was at least thriee that number; but Epaminondas chiefly trusted to his horse, in which he had much the advantage both in quality and good management. The rest he endeavoured to supply by the disposition of his men, and the vigour of his attack. He even refused to suffer any to serve under him in the engagement, but such as he knew to be fully resolved to conquer or die. The two armies met at Leuctra, where the Spartans were defeated with great slaughter, as related under that article.

The Athenians jealous of the Thebans.

The Thebans invade Peloponnesus, but are repulsed.

The victorious general, desirous to improve this great victory, sent a herald, crowned with garlands, to communicate it in form to the Athenians, in hopes that this would be an effectual means to reunite them to the Theban interest. But the Athenians, who now looked upon them with a jealous eye, and had in view the sovereignty of Greece, would not even grant their herald an audience. The Thebans took care to strengthen themselves by alliances; and, besides the Arcadians and Eleans, had brought the Phocians, Locrians, Acarnanians, Eubœans, and other states, under their dependence; so that they were now in a condition to act offensively against the Spartans. Accordingly, under pretence of assisting the Arcadians, they entered Peloponnesus with a gallant army, with Epaminondas and Pelopidas at its head. Here they were joined by the Arcadian and other confederate forces; so that the whole amounted to 40,000, or, according to some accounts, 50,000 men, besides great numbers of those who followed the camp, rather for plunder than fighting, and were computed at about 20,000 more. The army was divided into four columns, and moved towards Sellasia, the place of rendezvous, from which they pursued their march with fire and sword towards Sparta. But here they were repulsed by Agesilaus, who was then returned to that metropolis.

The Messenians restored to their ancient dominions.

The Corinthians defeated.

Epaminondas and Pelopidas disgraced at Thebes.

To repair, in some measure, this disgrace, and at the same time to leave some lasting monument which should redound as much to his glory as to the mortification of the Spartans, Epaminondas left not their territories till he had restored the posterity of the Messenians to their ancient dominions, from which they had been banished nearly 300 years; rebuilt their capital, and left a strong garrison for its defence. He was, however, nearly cut off in his return by Iphicrates, whom the Athenians had sent with 12,000 men to intercept him; but this general loitered so long at Corinth, that the Thebans had passed the defiles of Cenchreæ, the chief place where he could have obstructed their retreat had he taken possession of it in proper time. Epaminondas continued his march till he came in full view of the city of Corinth. He found the roads choked up with trees, rocks, stones, and every thing that could render them impassable; and the Corinthians well fortified, and resolute on a stout defence. But he advanced so furiously upon them, notwithstanding all these difficulties, that they abandoned all their intrenchments and outworks to the Thebans, and fled into the city. Thither these pursued them sword in hand, and made a horrid slaughter; insomuch that Corinth must inevitably have fallen into their hands had their generals thought fit to pursue these advantages; but whether they were afraid of the Athenians falling upon them, or apprehended some dangerous ambush in a country with which they were but indifferently acquainted, or whether the army was too much weakened through so many fatigues, or, lastly, whether the coldness of the season, it being then the depth of winter, would not permit them to proceed farther, they immediately marched towards Bœotia. This gave such an advantage to their enemies, that they met with a very mortifying reception on their return to Thebes, where they were both arrested, and seized as state-prisoners, for having presumed to prolong their command four months longer than the time limited by law, which time included almost the whole of their expedition from their first entrance into Peloponnesus. At last, however, the judges being ashamed to proceed any further, they were both honourably acquitted. This prosecution had been chiefly carried on and encouraged by Meneclides, a discontented Theban, and a bold and able speaker, who by his artful calumnies at the trial, had so far prevailed with the judges as to get Epaminondas deprived of the government of Bœotia for a whole year, though he could not gain the same advantage against Pelopidas, who was a greater favourite of the people, as being his senior.

War renewed with Sparta.

The Thebans repulsed.

Epaminondas degraded.

By this delay the Spartans, with much difficulty, had recovered themselves from their great defeat at Leuctra, and settled their affairs in as good a posture as they could; but though they had repulsed the Thebans in Peloponnesus, yet from the exploits which they had performed there, especially in dismembering the whole kingdom of Messenia from them, they had still cause to fear what their forces might accomplish under two such generals, and had accordingly taken due care to strengthen themselves against them, and to provide a great number of auxiliaries from other states, especially from that of Athens, with whom they had renewed their old treaty, and had agreed that each should have the command five days alternately. Soon after this treaty the Arcadians renewed the war, and took Palene in Laconia by storm, put the garrison to the sword, and were presently assisted by the Argives and Eleans, and especially by the Thebans, who sent to them 7000 foot, and 500 horse under the command of Epaminondas. This measure so alarmed the Athenians that they immediately sent Gobrias with some forces to oppose his passage; and he so behaved himself against the Thebans that they were a second time forced to abandon Peloponnesus. This ill success gave fresh occasion to the enemies of Epaminondas to blame his conduct in the highest terms, notwithstanding the singular bravery with which he and his troops had forced the pass. Even his friends could not but suspect him of partiality for the Spartans, in not pursuing his advantage over them, and making a greater slaughter of them when he had it in his power; while his enemies made it amount to no less than treachery to his country; so that their brave general was once more deprived of the government of Bœotia, and reduced to the condition of a private man. He did not continue long under this disgrace before an occasion offered to make his services again of such necessity to the state, as to give him an opportunity to retrieve his fame, and wipe off the stain which his enemies had thrown upon him.

Pelopidas seized by Alexander of Pheræ.

The Thessalians, who had groaned some time under the tyranny of the usurper Alexander, surnamed the Pheræan, sent an embassy to Thebes to implore their aid and protection; upon which Pelopidas was immediately sent as ambassador to expostulate with him on their behalf. He was then in Macedon, from whence he took the young prince Philip, afterwards the celebrated monarch, in order to protect and educate him; and upon his return marched directly to Pharsalus in Thessaly, in order to punish the treachery of some mercenaries who had deserted the Thebans in that expedition; but when he came thither he was surprised to be met by the tyrant at the head of a numerous army before that city, while he himself was only accompanied by a very small band. Acting as if he had supposed that Alexander came hither to justify himself, and answer to the complaints alleged against him, he advanced, with Ismenias his colleague, unarmed and unattended, not doubting but his character as ambassador from so powerful a republic, joined to his own character and authority, would protect them from insult or violence; but he found himself mistaken, for Alexander had no sooner got them into his hands, than he caused them to be seized and sent prisoners to Pheræa.

A Theban army sent to rescue him, defeated.

Epaminondas restored.

The Thebans highly resenting the indignity offered to their ambassadors, sent immediately an army into Thessaly; but the generals were repulsed with great loss by the usurper; and it was owing to Epaminondas, who was among them only as a private centinel, that they were not totally cut off. For the Thebans, finding themselves in such imminent danger, which they attributed to the incapacity of their generals, had immediately recourse to him, whose valour and experience had been so often tried; and, partly by persuasions and entreaties, and partly by threats, obliged him to take the command. This soon gave a different turn to their affairs, and converted their flight into a safe and regular retreat; for he took the horse and light-armed foot, and placed himself at their head in the rear, and charged the enemy with such vigour and bravery, that he obliged them to desist from their pursuit.

Rescues Pelopidas.

As the army had suffered such loss as not to be able to pursue them in their turn, he was obliged to march for Thebes, accompanied by the pusillanimous generals. They were fined 12,000 drachms each, and Epaminondas was reinstated in the command, and sent with a new reinforcement to repair the late dishonour, and prosecute their revenge. The news of his being in full march greatly alarmed Alexander; but the general, preferring the safety of his imprisoned colleague to all other considerations, forbore pushing hostilities to extremes, for fear of provoking the enemy to wreak all his fury on him. He contented himself for a while hovering about with his army, and now and then with such slight skirmishes as should intimidate the tyrant, and bring him the sooner to make some satisfactory offers. Alexander being fully convinced of the superiority of the Theban general, was glad to accept of a truce of thirty days, and to release Pelopidas and Ismenias; upon which Epaminondas immediately withdrew his forces, and returned with them to Thebes.

Success of Pelopidas at the Persian court.

By this time Thebes was raised to a sufficient height of reputation and glory to begin to aim in earnest at the sovereignty of Greece. The main obstacle to it was, that the other states grew so jealous of her present greatness, as to enter into the strongest alliances and confederacies to prevent its further growth; so that being now unable to procure many allies at home, they made no difficulty to seek for them abroad; and the Lacedæmonians, by setting the example, gave them a plausible pretence to follow their steps, and procure an alliance with Persia, which at that time they found was ready to accept of the offers on any terms; the only question was, which of the three states should be preferred, Sparta, Athens, or Thebes. At the same time the Thebans proposed to their new confederates to send proper deputies to the Persian court, in order to support their respective interests. These were the Arcadians, Eleans, and Argives, at the head of whose deputation Pelopidas was sent on behalf of the Thebans; and the Athenians being apprized of these proceedings, likewise sent two deputies. Being all arrived at the Persian court, they began to pursue each their respective interests; but Pelopidas had by that time gained such credit, both for his singular address and his extraordinary exploits, that he was distinguished in a particular manner from all the other deputies, and was received by the king with manifest marks of honour and esteem, who freely owned himself convinced that the Thebans were the people on whom he could most safely depend; and after having greatly applauded the equity of his demands, he ratified and confirmed them with great readiness, to the no small mortification of the other states. The substance of them was, that the liberties formerly granted to the other towns of Greece should be confirmed, that Messenia in particular should continue free and independent on the jurisdiction of Sparta; that the Athenians should lay up their fleet; and that the Thebans should be looked upon as the ancient and hereditary friends of Persia.

The Thebans propose to build a fleet.

The Thebans took advantage of the dissensions which prevailed among the Greeks as a pretence for increasing their forces; and Epaminondas thought it a proper opportunity for his countrymen to make a bold effort to obtain the dominion at sea, as they had in a great measure obtained it at land. He proposed it to them in a public assembly, and encouraged their hopes from the experience of the Lacedæmonians, who in Xerxes's time had, with ten ships only at sea, gained the superiority over the Athenians, who had no fewer than 200; and added, that it would now be a disgrace to Thebes to suffer two such republics to engross the command of so extensive an element. The people readily adopted his proposal, not without extraordinary applause, and immediately ordered 100 galleys to be equipped; and in the mean while sent him to Rhodes, Chios, and Byzantium, to secure those states in their interest, and procure what assistance he could from them. His negociations had all the success that could be wished for, notwithstanding the strenuous opposition of the Athenians, and of their admiral Laches, who was sent with a powerful squadron against him. But what more effectually thwarted all his measures, was the work which they found for him by land, and the obliging the Thebans to take part in the quarrels which then reigned among their neighbours; so that whatever projects they had concerted proved abortive for the present; and the death of Epaminondas, which happened not long after, put an effectual stop to them.

The city of Orchomenos razed.

Pelopidas marches against the Thessalian tyrant.

During the absence of that general, and of his colleague Pelopidas, the Orchomenians, being incited by some Theban fugitives, had formed a design to change the Theban government into an aristocracy; and 300 horsemen of the former had been actually despatched to carry it into execution. Their project, however, was seasonably discovered by the vigilance of the magistrates, who caused them to be seized and immediately put to death. They next sent a sufficient force against the city of Orchomenos, with orders to slay all the men, and to sell all the women and children for slaves, which was punctually done; after which they razed that noble city to the ground. Pelopidas was then on his way to Thessaly at the head of a powerful army, whither he had been sent to assist the Thessalians, who still groaned under the tyranny of Alexander the Pheræan, and had made several brave efforts to recover their liberty, but had been still overpowered by that usurper. Being joined by the Thessalians, he encamped in the face of the enemy, though far superior in number, and consisting of above 20,000 men. A fierce engagement soon ensued, in which both sides fought with uncommon bravery. The place where the battle was fought was called Cynocephala, from several little hills on it, between which there ran a large plain. Both armies endeavoured at first to post themselves on these eminences with their foot, while Pelopidas ordered his cavalry to charge that of the enemy below; which they did with such success that they soon put them to the rout, and pursued them over the plain. This obliged the tyrant to gain the tops of the hills, where he greatly annoyed the Thessalians that endeavoured to force those ascents; so

Is killed.

that Pelopidas was obliged to give over his pursuit and come to their relief. This immediately inspired the Thessalians with fresh courage. They again began to charge the enemy at several onsets, and soon threw them into such disorder that they were forced to give way. Pelopidas no sooner perceived the advantage, than he began to look for Alexander, with a design of engaging him. Having descried him as he was commanding his right wing, and endeavouring to rally his men, he moved directly to him; and having approached so near as to be heard by him, challenged him to decide the battle by single combat. Alexander, instead of accepting the offer, turned about, and, with all the speed he could, ran to screen himself among his guards. Upon this Pelopidas charged him with such furious speed that he obliged him to retire farther, and shelter himself within the thickest ranks; the sight of which made him attack with fresh vigour, and fight more desperately against him. He tried in vain several times to break through their ranks to reach him, cutting down great numbers of those that came forward to oppose him. His eagerness at length exposed him so far to the darts that were discharged from a distance, that some of them penetrated his armour, and gave him one or two desperate wounds, when some of the enemy advanced, and stabbed him in the breast with their spears.

Alexander defeated,

It is scarcely possible for words to express the grief and despair which not only his brave Thebans, but likewise the Thessalians and other allies, showed at the sight of their slain general. Some of the latter who had perceived the danger to which he was exposed, descended from the hill with all possible speed to his relief; but when they perceived that they had come too late to save him, both they and the rest of the little army thought of nothing but how to avenge his death. They rallied accordingly both horse and foot, as quickly as possible, and began to charge the enemy afresh, and with such desperate fury that they at length gained a complete victory over them, and killed above 3000 in the pursuit, besides a much greater number which they had slain on the field of battle, though they still looked upon all these advantages as too small to compensate the loss of their brave general.

and at last murdered.

The news of his death had no sooner reached Thebes, than the whole city was seen in as deep mourning as his army. They however sent a reinforcement of 7000 foot and 700 horse, as well to revenge the death of that general, as to improve the victory which he had gained over the enemy. The Thebans then fell so furiously on them, that they quickly broke and totally defeated the shattered remains of Alexander's army. He was forced to sue for peace, and to accept it on such conditions as the conquerors thought fit to impose. He was at length despatched in his bed by his wife Thebe, assisted by her brothers, about seven years after his defeat. His body was afterwards dragged along the streets, trodden under foot, and left a prey to the dogs.

Ambition of the Thebans.

Epaminondas displeases the states of Greece.

All this while the Thebans were watching to improve every commotion that happened, every success they gained, to the forwarding of their reigning and favourite project of increasing their power above all the rest, and in their turn of giving laws to Greece. Their late success in Thessaly, and the rupture between the Arcadians and Mantineans at the same time, about some consecrated money which the former had taken out of the temple of Olympia to pay their troops employed against the Eleans, and which the latter called a downright sacrilege, besides other discords that reigned in the other states of Greece, gave fresh encouragement to Thebes to offer her arbitration in those disputes. Those who had embezzled the sacred money, and wanted rather to embroil matters than to have them brought to light, informed the Thebans that the Arcadians were on the point of revolting to the Spartans, and advised them to come and defeat their design. At the same time they despatched some private directions to a Theban officer at Tegea, to apprehend several of their own people as disturbers of the peace. This was accordingly done, and several eminent persons were confined as prisoners of state. They were soon after discharged, and loud complaints were made against such arbitrary and unjust proceedings. The officer was accused before the Theban senate of having intermeddled in their affairs, and endeavoured to interrupt the good correspondence between the two states. It was even urged by some of the Tegeans that he should be indicted; while the more moderate, who foresaw the consequences which were likely to attend such appeals, and that it would infallibly bring the Thebans upon them, loudly protested against their marching into their territories, and did all they could to prevent it. The Thebans, however, were become too powerful and ambitious to miss so fair an opportunity of once more obtaining a footing in Peloponnesus, as they had long ago premeditated; and Epaminondas was so far from making a secret of their design, that he told the Arcadian deputies in justification of it, that as it was on their account that the Thebans engaged in the war, they had acted treacherously with them in making peace with Athens without their consent; but that when he had joined his army on his march into Peloponnesus to assist his friends, he would soon see what proofs the Arcadians would give of their fidelity. This speech did not fail to occasion great alarm, especially as it was spoken in such a magisterial style and threatening tone. Even those who were best affected to the Thebans could not forbear expressing their dislike of it; and all those who had the welfare of Peloponnesus at heart readily agreed with the Mantineans, that no time was to be lost in using all proper means to prevent the impending storm.

A combination against Thebes.

Epaminondas makes an unsuccessful attempt on Sparta,

and on Mantinea.

Athens and Sparta were accordingly applied to, and were easily prevailed upon to assist the Mantineans, and to come into a strict confederacy against the Thebans; and in order to prevent all disputes about the command of the army, it was agreed that each state should have it in its own territories; which plainly shows how terrified they all were at the apprehension of a fresh invasion of the Thebans. This was a point which neither the Spartans nor Athenians would so readily have given up to the Arcadians, though these had formerly as strenuously insisted upon it, even when they were almost reduced to the last extremity, and had never been able to obtain it till now. But Epaminondas was then in full march at the head of his Bœotian troops, with some Eubœan auxiliaries, and a body of stout Thessalian horse; and was moreover to be joined by the Messenians, Argives, and several other nations, as soon as he had entered Peloponnesus. The confederate army against him had ordered their rendezvous at Mantinea, the place which they naturally concluded would be first attacked, as being the chief seat of those who had revolted from the Thebans. But while they were securing themselves on that side, Epaminondas, who wisely considered how far this confederacy and expedition must have drained the city of Sparta of its main strength, broke up privately from Nemæa, where he had lain for some time encamped, and marched all that night with a design to have surprised that important capital. His project being discovered, the vigilant king took care to disconcert it; so that, though the Theban general made several vigorous assaults on that city, he was so stoutly repulsed, and the Spartans behaved with such intrepid valour, that he was forced to retire and turn his thoughts against Mantinea, which he judged by this time to have been quite defenceless. He indeed judged rightly; for the place was not only drained of its troops, but likewise of its inhabitants, who took that opportunity, while the scene of war was in Lacedæmon, to gather in their harvest, and were scattered all over the country; so that he would not have met with any difficulty in gaining the town, had not the Athenian auxiliaries come unexpectedly to its relief, and given him a fresh repulse.

These two last defeats greatly exasperated the Theban general, who had never before experienced such disasters, and could not but foresee that they would not only lessen his reputation with his allies, but, if not speedily retrieved, would sully the glory of all his former exploits. What added to his present difficulties was, that the time allotted him for his expedition was almost expired; so that he had but a short space left to undertake some brave achievement, which might recover his and his country's honour, and keep up the spirits of his auxiliaries, and those under his protection. He was moreover in the midst of his enemy's country, and saw plainly enough how narrowly they watched all his motions, and how well prepared they were to oppose him whatever attempt he resolved upon, whether to attack them or to retreat. Under all these difficulties, he rightly considered that he must immediately resolve upon a decisive battle; in which, if his pristine fortune followed him, he might at once retrieve his affairs, and make himself master of Peloponnesus; or, if that failed him, as it lately had done, fall honourably in the attempt. In this engagement Epaminondas made the wisest disposition of his troops, attacked and fought with the most intrepid courage and conduct, and had opened himself a way through the Spartan ranks, thrown them into the utmost confusion, and made a terrible slaughter of them, insomuch that the field of battle was covered with their wounded and slain, when, in the heat of the fight, having ventured himself too far in order to give them a total overthrow, the enemy rallied again, pouring with their whole fury three volleys of darts upon him, some of which he drew out and returned to them, till at length, being covered with wounds, and weakened with the loss of so much blood, he received a mortal wound from a javelin, and was with great difficulty rescued from the enemy by his brave Thebans, and brought alive, though speechless, into his tent. As soon as he had recovered himself, he asked his friends that were about him what was become of his shield; and being told that it was safe, he beckoned to have it brought to him, and kissed it. He next inquired which side had gained the victory; and being answered, the Thebans, he replied, then all is well: and upon observing some of his friends bewail his untimely death, and leaving no children behind him, he is said to have answered, "Yes; I have left two fair daughters, the victory of Leuctra, and this of Mantinea, to perpetuate my memory." Soon afterwards, upon drawing the point of the javelin out of his body, he expired.

The consequence of this great general's fall, and of the bloody fight in which neither party could boast any great advantage over the other, after a great loss of men on both sides, insomuch that Xenophon makes it a drawn battle, was, that both parties agreed on a cessation of arms, and parted, as it were by consent, to take care of their wounded and slain. The Thebans indeed thus far gained the greater share of glory, that they renewed the fight, and after a most desperate contest, obtained a victory over those Spartans that opposed them, and rescued the body of their dying general out of their hands. But an effectual end was put to this bloody war, and a general peace agreed on by all but the Spartans, who refused it only because the Messenians were included in it. As to the Thebans, they had no great reason to boast of this dear-bought victory, since their power and glory began to decline from that very time; so that it may be truly said, that it had risen and set with their great general.

On the death of Epaminondas, the Thebans relapsed into their former state of inactivity and indolence; and at last having ventured to oppose Alexander the Great, their city was taken, and the inhabitants slaughtered for several hours, after which the buildings were destroyed. It was rebuilt by Cassander, but never afterwards made any considerable figure among the states of Greece. About the year 146 B. C. it fell under the power of the Romans, under which it continued till the extinction of their empire by the Turks. It is now called *Thive*, and, according to Dr Clarke, is about two and a half English miles in circumference. It contains about 300 houses, and many interesting antiquities. The present inhabitants live chiefly within what was anciently the citadel. The circuit of the walls can yet be traced, and many parts of them are still standing. There were two mosques in Thebes, and a great many Greek churches. It is seated between two small rivers, at the south-west side of a large plain, in long. 23. 40. E. and lat. 38. 17. N.

THEBES, in Egypt, one of the most renowned cities of the ancient world. It was also called *Diospolis*, or the city of Jupiter, and was built, according to some by Osiris, according to others by Busiris. Its length, in Strabo's time, was 80 furlongs, or ten miles; but this was nothing in comparison of its ancient extent, before it was ruined by Cambyses, which, we are told, was no less than 420 stadia, or 52 miles and an half. The wealth of this city was so great, that, after it had been plundered by the Persians, what was found on burning the remains of the pillage, amounted to above 300 talents of gold and 2300 of silver.

Mr Bruce visited the ruins of this celebrated city; but informs us that nothing now remains except four temples, and these neither so entire nor magnificent as others at Dendera. Thebes has been celebrated by Homer for its hundred gates; but Mr Bruce informs us, that no vestiges of these are now remaining, neither can we discover the foundation of any wall it ever had; "and as for the horsemen and chariots it is said to have sent out, all the Thebaid sown with wheat would not have maintained one half of them. Thebes, at least the ruins of the temples called *Medinet Tabu*, are built in a long stretch of about a mile broad, most parsimoniously chosen at the sandy foot of the mountains. The *Horti Pensiles*, or hanging gardens, were surely formed upon the sides of these hills, then supplied with water by mechanical devices. The utmost is done to spare the plain, and with great reason; for all the space of ground this ancient city has had to maintain its myriads of horses and men, is a plain of three quarters of a mile broad between the town and the river, upon which plain the water rises to the height of four and five feet. All this pretended populousness of ancient Thebes I therefore believe to be fabulous." After examining the ground on which Thebes is supposed to have stood, he concluded that it had no walls, and that consequently Homer's story of its having an hundred gates is misunderstood. The mountains of the Thebaid stand close behind the town, not in a ridge, but standing single, so that you can go round each of them. A hundred of these are said to be hollowed out for sepulchres and other purposes. These, he thinks, were the hundred gates of Homer; in proof of this they are still called by the natives *Beeban el Meluke*, the ports or gates of the kings. All that is said of Thebes by poets or historians after the days of Homer is meant of Diospolis, which, as its name testifies, was built by the Greeks, long after Thebes was destroyed; though Diodorus says it was built by Busiris. It was on the east side of the Nile, whereas ancient Thebes was on the west, though both are considered as one city. See EGYPT.

Themistius.

THEMISTIUS, a Greek orator and philosopher, was a native of Paphlagonia, and flourished during the latter half of the fourth century. He became very eminent as a public teacher of philosophy, and distinguished himself by commentaries on some of the works of Aristotle. His eloquence procured him the appellation of Εὐφραδὴς, or the Eloquent. At Constantinople he taught for twenty years. Having been invited to Rome, he removed to that city, but, after an interval of two years, returned to his former place of residence, and there spent the remainder of his life. He was married, and had children. Although he adhered to the pagan superstitions, Constantius admitted him to the senate in the year 355; and his panegyrical oration on that emperor procured him the honour of a statue. From Julian, a pagan and a philosopher, he received in 362 the higher distinction of being nominated præfect of Constantinople. In 384 he obtained the same appointment from Theodosius the Great.

Themistius is regarded as one of the best writers of this declining age of Grecian literature. The first edition of his works, including commentaries on Aristotle, and only eight orations, was published by Trincavellus, Venet. 1534, fol. His orations afterwards found a very learned editor, Dionysius Petavius, who published two different editions, Flexiæ, 1613, 8vo, Paris. 1618, 4to. This second edition contains nineteen orations; but thirty-three are included in the edition of Hardouin, Paris. 1684, fol. To this number an addition has lately been made by Angelo Mai: "Themistii Philosophi Oratio in eos a quibus ob Præfecturam susceptam fuerat vituperatus, inventore et interprete Angelo Maio, Bibliothecæ Ambrosianæ a LL. OO." Mediolani, 1816, 4to & 8vo.

THEMISTOCLES, the renowned Athenian admiral, general, and patriot, who gained the battle of Salamis against the Persians. Being banished his country by his ungrateful fellow-citizens, he fled to Artaxerxes king of Persia; but, in order to avoid taking up arms against his country, he slew himself, 464 B. C. See ATHENS.

THEOBALD, LEWIS, best known as an editor of Shakspeare, was the son of an attorney practising at Sittingbourne in Kent. His grammatical learning he received at Isleworth in Middlesex, and was originally destined for his father's profession; but this he speedily abandoned for the profession of an author, and having fixed his residence in the metropolis, he engaged in a variety of literary undertakings. To Mist's Weekly Journal he contributed a paper called "The Censor;" and his censures being pronounced with great freedom, gave no small offence to some writers more formidable than himself. One of those whom he provoked was the rabid Dennis. Pope's translation of Homer he at first extolled, and afterwards abused. He was the original hero of the Dunciad, but was displaced to make room for Cibber, to whom the poet's satire is in many instances inapplicable. Theobald endeavoured to avenge himself by publishing "Shakespeare restored; or, a Specimen of the many Errors as well committed as unamended by Mr Pope in his edition of this poet, designed not only to correct the said edition, but to restore the true Reading of Shakespeare in all the Editions ever yet published." Lond. 1726, 4to. This prelude was after a considerable interval followed by his edition of Shakspeare's Works, Lond. 1733, 7 vols. 8vo. In 1726 he had introduced on the stage "The double Falsehood, or, the distrest Lovers;" of which, as he averred, the greater part was written by Shakspeare. His arguments in favour of this hypothesis were not considered as satisfactory; and, according to the opinion of Dr Farmer, this drama was the production of Shirley. Theobald was the author or translator of twenty plays, enumerated in the Biographia Dramatica, vol. i. p. 706. He was likewise concerned in various translations; and at the time of his death he had made some progress in an edition of Beaumont and Fletcher. He died in the month of September 1744.

THEOCRACY, in matters of government, a state governed by the immediate direction of God alone. Such was the ancient government of the Jews before the time of Saul.

THEOCRITUS, the most famous of all the pastoral poets, was the son of Praxagoras and Philine. He was a native of Syracuse, and flourished about 272 years before the Christian era.[1] The younger Hiero, king of Syracuse, is celebrated in his verses; but he appears to have found a more liberal patron in Ptolemy Philadelphus, who attracted him to the Egyptian court, and of whom he speaks in terms of high commendation. Of his personal history, we possess no further memorials on which we can place much reliance. The pastorals of Theocritus, which have furnished models to all succeeding poets, are remarkable for their simplicity, very frequently elegant, but sometimes approaching to rudeness. They are written in the Doric dialect, which is peculiarly adapted for such compositions Thirty idyls bear his name, but it has been doubted whether they were all produced by the same poet. To him are likewise ascribed twenty-two epigrams; and the authorship of one or two fantastic productions he disputes with Simmias.

The first edition of Theocritus, containing only eighteen idyls, issued from Milan, along with the "Opera et Dies" of Hesiod. It is a folio volume, without date, but is supposed to have been printed in 1493. The edition of Aldus appeared in 1495, that of Junta in 1515; and the earliest edition accompanied with the scholia, at Rome in 1516. The best of the old editions is that of Daniel Heinsius, Ex bibliopolio Commeliniano, 1604, 4to. Beside the notes of the editor, it includes those of Joseph Scaliger and Isaac Casaubon. Among the more remarkable editions, we must not overlook that of Reiske, Lipsiæ, 1765-6, 2 tom. 4to. He was speedily followed by a more elegant, though not a more learned editor, Thomas Warton, Oxon. 1770, 2 tom. 4to. The preface is elegantly written, and the annotations display a more than ordinary degree of refined taste, but this splendid edition is not without its defects. One of these is the inconvenient arrangement of the Greek scholia, nor is the rejection of the accents to be commended. A valuable edition of Theocritus, including likewise Bion and Moschus, was published by Valckenaer, Lugd. Bat. 1779, 8vo. The editions of Harles, Jacobs, Dahl, Schäfer, Heindorf, and Wüstemann, have each their share of merit. The poems of Theocritus are inserted in the first volume of Brunck's "Analecta veterum Poetarum Græcorum," and in the second volume of Gaisford's "Poetæ Minores Græci." Oxon. 1816-20, 4 tom. 8vo. The scholia are to be found in the fourth volume. Of the idyls of this poet, English translations were published by Thomas Creech in 1681, by Francis Fawkes in 1767, by Richard Polwhele in 1786, and by M. J. Chapman in 1836. Polwhele has likewise translated the epigrams of Theocritus.

THEODOLITE, a mathematical instrument for measuring heights and distances. See MENSURATION and SURVEYING.

THEODORE, BARON NIEUHOF, in the county of La Marc in Westphalia, an adventurer who obtained considerable notoriety under the title of King of Corsica. He had his education in the French service, and afterwards went to Spain, where he received some marks of regard from the duke of Riperda and Cardinal Alberoni; but being of an unsettled disposition, he quitted Spain, and travelled into Italy, England, and Holland, in search of new adventures. He at last fixed his attention on Corsica, and formed the scheme of rendering himself sovereign of that island. He was a man of abilities and address; and having fully informed himself of every thing relating to Corsica, went to Tunis, where he devised means to procure some money and arms; and then went to Leghorn, from whence he wrote a letter to the Corsican chiefs Giafferi and Paoli, offering considerable assistance to the nation if they would elect him as their sovereign. This letter was consigned to eodor.

Theodoretus || Theognis.

Count Domenico Rivarola, who acted as Corsican plenipotentiary in Tuscany, and he gave for answer, that if Theodore brought the assistance which he promised to the Corsicans, they would very willingly make him king. Without loss of time he set sail, and landed at Tavagna in the spring of the year 1736. He was a man of a very stately appearance, and the Turkish dress, which he wore, added to the dignity of his mien. He had a few attendants with him; and his manners were so engaging, and his offers so plausible, that he was proclaimed king of Corsica before Count Rivarola's despatches arrived to inform the chiefs of the terms upon which he had agreed. He brought with him about 1000 zequins of Tunis, besides some arms and ammunition, and made magnificent promises of foreign assistance; whence the Corsicans, who were glad of any support, willingly gave in to his schemes. Theodore instantly assumed every mark of royal dignity. He had his guards and his officers of state; he conferred titles of honour, and struck money both of silver and copper. The silver pieces were few in number, and can now hardly be met with; the copper coins have on one side T. R., that is, "Theodorus Rex," with a double branch crossed, and round it this inscription, Pro bono publico Re. Co., that is, "For the public good of the kingdom of Corsica:" on the other side is the value of the piece, *Cinque solidi*, or five sous.

The Genoese were not a little confounded with this unexpected adventure. They published a violent manifesto against Theodore, treating him with great contempt; but at the same time showing they were alarmed at his appearance. Theodore replied in a manifesto, with all the calmness and dignity of a monarch; but after being about eight months in Corsica, perceiving that the people began to cool in their affections towards him, he assembled his chiefs, and declared he would keep them no longer in a state of uncertainty, being determined to seek in person the support which he had long expected. He settled an administration during his absence, recommended unity in the strongest terms, and left the island with reciprocal assurances of fidelity and affection. He proceeded to Holland, where he was so successful as to obtain credit from several rich merchants, particularly Jews, who trusted him with cannon and other warlike stores to a great value, under the charge of a supercargo. With these he returned to Corsica in 1739; but by this time the French, as auxiliaries to the Genoese, had become so powerful in the island, that though Theodore threw in his supply of warlike stores, he did not incline to venture his person, the Genoese having set a high price on his head. He therefore again departed; and after many unavailing attempts to recover his crown, at length chose for retirement a country where he might enjoy the participation of that liberty which he had so vainly endeavoured to give his Corsicans; but his situation in England by degrees grew wretched, and he was reduced so low as to be several years before his death a prisoner for debt in the King's Bench. At length, to the honour of some gentlemen of rank, a charitable contribution was set on foot for him in the year 1753. Mr Boswell observes, that Horace Walpole generously exerted himself for the unfortunate Theodore, and wrote a paper in *The World* with great elegance and humour, soliciting a contribution for the unhappy monarch in distress, to be paid to Mr Robert Dodsley, bookseller, as lord high treasurer. This brought him a very handsome sum, and he was set at liberty. The same writer adds, that Mr Walpole had the original deed by which Theodore made over the kingdom of Corsica in security to his creditors, and that he also had the great seal of the kingdom. Theodore died on the 11th of December 1756, and was buried in St Anne's churchyard, Westminster, where, in 1757, a simple unadorned monument of marble was erected to his memory.

THEODORETUS, or, as he is frequently called, Theodoritus, was born at Antioch towards the close of the fourth century. According to his own account, his birth was preceded by divers miracles. He received his education in the neighbouring monastery of Euprepius, where he had Chrysostom for one of his instructors. About the year 420 he became bishop of Cyrus in Syria. His connection with Nestorius involved him in a charge of heresy; and in 449 the council of Ephesus deposed him from his bishopric; but in 451 the council of Chalcedon recalled him from exile, and restored him to his office. He survived till 457 or the following year. His works, compared with those of the other Greek fathers, are of very considerable value. He has written commentaries on most of the books of the Old Testament, and on the epistles of Paul. His ecclesiastical history, divided into five books, prosecutes the narrative from the year 322 to the year 427. It is printed with different editions of Eusebius, and the other Greek historians of the church. A collective edition of his works, with a Latin version, was published by Sirmond, Lutet. Paris. 1642, 4 tom. fol. A supplementary volume was added by Garnier in 1684. Another edition was long afterwards published by J. L. Schulze, Halæ Sax. 1769–74, 5 tom. 8vo. Each volume is however divided into two parts. Dr Gaisford has very recently published a valuable edition of his "Græcarum Affectionum Curatio," Oxon. 1839, 8vo. This treatise is important as a contribution to the history of philosophy, and its merits have been fully discussed by Luzac.

THEOGONY, from Θεὸς, *God*, and γονὴ, *seed*, *offspring*, that branch of the heathen theology which taught the genealogy of their gods. Hesiod gives us the ancient theogony in a poem under that title. Among the most ancient writers, Dr Burnet observes that theogony and cosmogony signified the same thing. In effect, the generation of the gods of the ancient Persians, fire, water, and earth, is apparently no other than that of the primary elements.

THEOGNIS, a Greek poet of a singular character, flourished in the 59th Olympiad, or about 544 years before the Christian era. According to Plato, who is followed by Suidas, he was a native of Megara in Sicily, but Harpocratio contends for Megara in Greece; and Corsini has satisfactorily shewn that the latter statement is much more probable.[1] Theognis commonly uses the Ionic dialect, and not the Doric of the Sicilians; and his verses afford several other indications of an Achaian origin. He speaks of himself as a person of superior birth. From his fellow-citizens, whoever they were, he experienced harsh treatment; and having been driven into exile with his wife Argyris, he found a place of refuge at Thebes. As he survived the Median war, B. C. 490, he must have reached a very advanced age;[2] but how or where he terminated his career, we find no information. His remaining work consists of a series of Γνῶμαι, or moral sentences, written in elegiac verse, and containing many pointed and striking sentiments, though some of them are not strictly moral. The name of the author's friend Cyrnus is very frequently introduced. Of this work there are many separate editions. It is likewise to be found in Brunck's "Gnomici Poetæ Græci," and in the first volume of Gaisford's "Poetæ Minores Græci." In the edition of Bekker (Lipsiæ, 1815, 8vo), one hundred and fifty-one verses are printed for the first time, and the total number is thus raised to 1389. A more recent edition, with a critical commentary and notes, was published by F. Th. Welcker, Francof. 1826, 8vo.

THEOLOGY.

Theology.

The word theology, in its most restricted sense, signifies a discourse concerning God, (λογος περι τον θεου); but it is commonly employed to designate that science which treats not only of the divine existence and attributes, but also of the relations which subsist between God and his intelligent creatures, the duties which consequently devolve upon the latter, and the arrangements which He has entered into for their government and benefit. More particularly it is used to designate the scientific development of the doctrines upon these points embraced by Christianity.

Obs. The word θεολογειν and its cognates were first used to denote the fables of those poets and philosophers who wrote of the genealogy and exploits of the gods of Greece. They were afterwards adopted by the earliest writers of the Christian church, who styled the author of the Apocalypse, by way of eminence, ὁ θεολογος, *the Divine.*

Having already, under the article Polytheism, treated of the origin and characteristics of *idolatry*, we are happily relieved from the necessity of here examining the theology of paganism; for although every pagan nation of antiquity had some tutelary deities peculiar to itself, they may yet be considered as having all had the same theology, since an intercommunity of gods was universally admitted, and the heavenly bodies were adored as the *dii majorum gentium* over the whole earth. The absurdities and inconsistency of the pretended revelation of the Arabian impostor, have also been sufficiently exposed under the words Alcoran and Mahometanism; so that the only theology of which we have to treat at present is the *Christian* theology. This comprises a body of science so important, that in comparison with it all other sciences sink into insignificance; for without a competent knowledge of the attributes of God, of the several relations in which he stands to us, and of the ends for which we were created, it is obvious that we must wander through life like men groping in the dark, strangers to the road on which we are travelling, as well as to the fate awaiting us at the end of our journey.

The Christian theology embraces both what has been called Natural Theology, and that which is peculiar to the scriptures of the Old and New Testaments. The distinction between these two is clear and well-founded.[a] At the same time, it is not of that kind which renders it necessary that the two should be treated separately; for as Christianity is no less a republication of the religion of nature, (see Hill's Divinity, b. ii. c. 3, 1), than an announcement of truths, of which the volume of nature bears no traces, the attempt to present the entire body of its theology in one continuous whole, necessarily involves the statement both of the doctrines of natural, and those of Biblical theology.

[a] Concerning the extent of natural theology many opinions have been formed, while some have contended that there is no such thing. Into these disputes we mean not at present to enter. We believe that one of them could have had no existence among sober and enlightened men, had the contending parties been at due pains to define with accuracy the terms which they used. Whatever be the origin of religion, it is obvious, that no man can receive a written book as the word of God, till he be convinced by some other means that God exists, and that he is a Being of power, wisdom, and goodness, who watches over the conduct of his creature man. If the progenitor of the human race was instructed in the principles of religion by the Author of his being, (a fact of which it is difficult to conceive how a consistent theist can entertain a doubt), he might communicate to his children, by natural means, much of that knowledge which he himself could not have discovered had he not been supernaturally enlightened. Between illustrating or proving a truth which is already spoken of, and making a discovery of what is wholly unknown, every one perceives that there is an immense difference.[1]

To beings whose natural knowledge originates wholly from sensation, and whose minds cannot, but by much discipline, advance from sense to science, a long series of revelations might be necessary to give them at first just notions of God and his attributes, and to enable them to perceive the relation between the effect and its cause, so as to infer by the powers of their own reason, the existence of the Creator from the presence of his creatures. Such revelations, however, could be satisfactory only to those who immediately received them. Whenever the Deity has been pleased by supernatural means to communicate any information to man, we may be sure that he has taken effectual care to satisfy the person so highly favoured, that his understanding was not under the influence of any illusion; but such a person could not communicate to another the knowledge which he had thus received, by any other means than an address to his rational faculties. No man can be required to believe, no man indeed can believe, without proof, that another, who has no more faculties, either of sensation or intellect, than himself, has obtained information from a source to which he has no possible access. An appeal to miracles would in this case serve no purpose; for we must believe in the existence, power, wisdom, and justice of God, before a miracle can be admitted as evidence of any thing but the power of him by whom it is performed. See Miracle.

It is therefore undeniable that there are some principles of theology which may be called *natural;* for though it is in the highest degree probable that the parents of mankind received all their theological knowledge by *supernatural* means, it is yet obvious that some parts of that knowledge must have been capable of a proof purely rational, otherwise not a single religious truth could have been conveyed through the succeeding generations of the human race, but by the immediate inspiration of each individual. We indeed admit many propositions as certainly true, upon the sole authority of the Jewish and Christian scriptures, and we receive these scriptures with gratitude as the lively oracles of God; but it is self-evident that we could not do either the one or the other, were we not convinced by natural means that God exists, that he is a being of goodness, justice, and power, and that he inspired with divine wisdom the penmen of these sacred volumes. Now, though it is possible that no man, or body of men, left to themselves from infancy in a desert world, would ever have made a theological discovery, yet whatever propositions relating to the being and attributes of the first cause and the duty of man, can be demonstrated by human reason, independent of written revelation, may be called *natural theology*, and are of the utmost importance, as being to us the first principles of all religion. Natural theology, in this sense of the word, is the foundation of the Christian revelation; for without a previous knowledge of it, we could have no evidence that the scriptures of the Old and New Testaments are indeed the word of God. On this subject many books have been published in our own and other languages; of which the following may be mentioned as the most valuable: Paley's Natural Theology, especially as edited by Lord Brougham and Sir Charles Bell, 4 vols. 12mo. Chalmers's Nat. Theol. Works, vol. i. and ii. Sumner's Records of the Creation, 2 vols. 8vo. The Bridgewater Treatises on the Power, Wisdom, and Goodness of God, &c., by Chalmers, Kidd, Whewell, Bell, Roget, Buckland, Kirby, and Prout.

---

[1] The discriminating powers of Aristotle will not be questioned; and in the following extract made by Cicero from some of his works which are now lost, he expresses our sentiments on this important subject with his usual precision:—"Præclare ergo Aristoteles, SI ESSENT, inquit, qui sub terra semper habitavissent, bonis, et illustribus domiciliis, quæ essent ornata signis atque picturis, instructaque rebus iis omnibus, quibus abundant ii, qui beati putantur, nec tamen exissent unquam supra terram: ACCEPISSENT AUTEM FAMA ET AUDITIONE, ESSE QUODDAM NUMEN, ET VIM DEORUM; deinde aliquo tempore, patefactis terræ faucibus, ex illis abditis sedibus evadere in hæc loca, quæ nos incolimus, atque exire potuissent; cum repente terram, et maria, cœlumque vidissent; nubium magnitudinem, ventorumque vim cognovissent, adspexissentque solem, ejusque tum magnitudinem, pulchritudinemque, tum etiam efficientiam cognovissent, quod is diem efficeret, toto cœlo luce diffusa: cum autem terras nox opacasset, tum cœlum totum cernerent astris distinctum et ornatum, lunæque luminum varietatem tum crescentis, tum senescentis, eorumque omnium ortus et occasus, atque in omni æternitate ratos, immutabilesque cursus; hæc cum viderent, PROFECTO ET ESSE DEOS, et HÆC TANTA OPERA DEORUM ESSE arbitrarentur."—*De Nat. Deorum*, lib. ii. § 37.

From this passage it is evident, that the Stagyrite, though he considered the motions of the heavenly bodies, the ebbing and flowing of the sea, and the other phenomena of nature, as affording a complete *proof* of the being and providence of God, did not however suppose that from these phenomena an untaught barbarian would *discover* this fundamental principle of religion. On the contrary, he expressly affirms, that before a man can feel the force of the evidence which they give of this important truth, he must have HEARD of the existence and power of God.

The principles of this science are to be found only in the WORD and WORKS of God; and he who would extract them pure and unsophisticated, must dig for them himself in that exhaustless mine. To fit a man for this important investigation, much previous knowledge is requisite. He must study the works of God scientifically, before he can perceive the full force of that testimony which they bear to the power, the wisdom, and the goodness of their author. Hence the necessity of a general acquaintance with the physical and mathematical sciences before a man enter on the proper study of theology, for he will not otherwise obtain just and enlarged conceptions of the God of the universe. He should also make himself acquainted with the principles of logic, the philosophy of the human mind, and the different sources of evidence. Above all, he should devote himself to the study of the original languages of scripture, and to the principles of Biblical criticism and interpretation. He who is incapable of consulting the original scriptures, must rest his faith, not on the sure foundation of the word of God, but on the credit of fallible translators; and if he be at any time called on to vindicate revelation against the scoffs of infidelity, he will have to struggle with many difficulties which are easily solved by him who is master of the original tongues.

Having satisfied himself of the Authenticity and Divine Authority of the Scriptures, (see SCRIPTURE and INSPIRATION), the student will set himself honestly, diligently, and devoutly to examine into their sacred contents, that he may therein learn for himself the system of truths which they contain.

Obs. "Impressed," says Mr. Tatham, (*Chart and Scale of Truth*), "with an awful sense of the importance of the sacred volume, the philosophical [scientific] divine will shake off the bias of prejudices, however formed, of opinions however sanctioned, and of passions however constitutional, and bring to the study of it the advantage of a pure and impartial mind. Instead of wasting all his labour upon a number of minute and less significant particulars, and of refining away plain and obvious sense by the subtleties of a narrow and corrosive mind, his first object will be to institute a theological inquiry into the general design of the written word, and from principles fully contained and fairly understood, to illustrate the true *nature* and *genius of the religious dispensation* in all its parts. He will mark the difference between the first and second covenants, and observe the connection that subsists between them. He will trace the temporary economy of the *Old Testament*, and weigh the nature and intent of the *partial covenant* with the Jews; observing with astonishment how it was made introductory of better things to come: and he will follow it through the *law* and the *prophets* in its wonderful evolutions, till he see this vast and preparatory machine of providence crowned and completed in the eternal gospel. This *New Testament*, the last and best part of the religious dispensation, he will pursue through the sacred pages of that gospel with redoubled attention; contemplating the divine foundation on which it claims to be built, the supernatural *means* by which it was executed, and the immortal end which it has in view."

In the course of this inquiry into the import of the sacred volume, the student will pay particular attention to the circumstances of the age and country in which its various writers respectively lived, and to the nature of the different *styles, analogical*, and *parabolical*, in which it is written. He will likewise keep in mind that God, whom it claims for its author, is the parent of truth, and that all his actions and dispensations must be consistent with one another. He will therefore compare the different passages of the Old and New Testaments which relate to the same doctrine, or to the same event, reasonably concluding that the Bible must be the best interpreter of itself; and though the opinions which he thus forms may often be erroneous, they will seldom be dangerous errors, and may easily be corrected by mature reflection, or by consulting approved authors who have treated before him of the various points which have been the subject of his studies. Of this mode of proceeding one good consequence will be, that, having from the sacred scriptures formed a system of theology for himself, he will afterwards study the systems of other men without any violent prejudices for or against them; he will be so much attached to his own opinions, as not to relinquish them in obedience to mere human authority, at the same that he will be ready to give them up when convinced that they are not well-founded; and if he have read the scriptures attentively, he will have acquired such a love of truth as to embrace her wherever she may be found.

No small assistance will be obtained in this inquiry by an acquaintance with the history of theological opinions, and of the different controversies which have at different periods, or more continuously, agitated the church.[b] It has indeed been long fashionable to decry polemical divinity as an useless, if not a pernicious, study; but it is not impossible that this fashion has had its origin in ignorance, and that it tends to perpetuate those schisms which it professes to lament. We are, however, far from recommending to the young divine a perusal of the works of the several combatants on each side of a disputed question, till he has fitted himself for judging between them by a long course of preparatory study; and no preparation can better fit him for this purpose, than an impartial study of ecclesiastical history. He who has with accuracy traced the progress of our holy religion from the days of the apostles to the present time, and marked the introduction of new doctrines, and the rise of the various sects into which the Christian world is divided, is furnished with a criterion within himself, by which to judge of the importance and truth of the many contested doctrines: while he who, without this preparation, shall read a multitude of books on any religious controversy, will be in danger of becoming a convert to his last author, if that author possess any tolerable share of art and ingenuity.

The student will find it further of advantage to compare his own conclusions with those which have been arrived at and advocated by the most distinguished writers upon systematic theology. He will thus be enabled to verify his own opinions where they are sound, and to modify or correct them where they are erroneous.

Obs. Systems of theology abound both in our own and in other languages. The following appear especially worthy of the attention of the student: LATIN.—Phil. Melanchthonis *Loci Communes Theologici*, 1521, denuo edidit Augusti, 8vo, 1821. J. Calvini *Institutiones Rel. Christ.*, 1536, denuo ed. Tholuck, 2 tom. 8vo, 1834, 5. J. Gerhardi *Loci Theologici*, 1610–22, denuo ed. Cotta, 20 tom. 4to, 1762–81. Fr. Turretini *Institutio Theol. Elencticae*, 3 tom. 4to, 1701. D. Hollazii *Examen Theol. Acroam.* 1707, denuo ed. Teller, 1763, 4to. J. Cp. Döderleinii *Institutio Theologi Christ. in capp. relig. theor. nostris temporibus accommodata*, 1780, ed. 6ta, a Junge, 1797, 8vo. Ric. Baxteri *Methodus Theologiae Christ.* fol. 1681. Herm. Witsii *De Oeconomia Foederum Dei cum Hominibus* lib. iv. 4to, 1693. Herm. Muntinghe *Pars theol. Christ. theoretica*, 2 vols. 8vo, 1800. ENGLISH.—Th. Ridgley's Body of Divinity, &c. 2 vols. fol. 1731; 4 vols. 8vo, 1819. Th. Gill's Body of Doctrinal and Practical Divinity, 2 vols. 4to, 1769; 3 vols. 8vo, 1796. Tim. Dwight's Theology explained and defended, in a series of Sermons, (many editions). G. Hill's Lectures in Divinity, 2 vols. 8vo, 1821; 2 vols. 12mo, 1833. Dick's Lectures on Theology, 4 vols. 8vo. Morren's Biblical Theology, 8vo, 1835. S. S. Schmucker's Biblical Theology, translated from the Works of Storr and Flatt, 8vo, 2d ed. 1836, (London, reprinted 1839.)

As much of our success, in all theological inquiries, depends upon the spirit and temper in which these are prosecuted, we commend to the attention of the reader the fol-

[b] See Stapferi *Theologiae Polemicae Institutiones*, 5 tom. 8vo, 1743–47. Reinhard *Theologia Polemica*, 8vo, 1745. Petavius *De Theologicis Dogmatibus*, 3 vols. folio, 1700. Augusti's *Christliche Dogmengeschichte*, 8vo, 1835; &c.

lowing solemn charge, with which the late Dr. Taylor of Norwich was wont to preface his Theological Lectures:

> "I. I do solemnly charge you, in the name of the God of Truth, and of our Lord Jesus Christ, who is the Way, the Truth, and the Life, and before whose judgment-seat you must in no long time appear, that in all your studies and inquiries of a religious nature, present or future, you do constantly, carefully, impartially, and conscientiously, attend to evidence, as it lies in the Holy Scriptures, or in the nature of things, and the dictates of reason; cautiously guarding against the sallies of imagination, and the fallacy of ill-grounded conjecture.
>
> "II. That you admit, embrace, or assent to no principle or sentiment by me taught or advanced, but only so far as it shall appear to you to be supported and justified by proper evidence from revelation or the reason of things.
>
> "III. That if, at any time hereafter, any principle or sentiment by me taught or advanced, or by you admitted or embraced, shall, upon impartial and faithful examination, appear to you to be dubious or false, you either suspect or totally reject such principle or sentiment.
>
> "IV. That you keep your mind always open to evidence: That you labour to banish from your breast all prejudice, prepossession, and party-zeal: That you study to live in peace and love with all your fellow-Christians; and that you steadily assert for yourself, and freely allow to others the unalienable rights of judgment and conscience."
>
> "BENE PRECASSE," said Luther, "EST BENE STUDUISSE."

Christian theology may be divided into *four* parts; the first, embracing the doctrines concerning God; the second, those concerning man; the third, those concerning the scheme of man's salvation through Jesus Christ; and the fourth, those respecting the means to be used by man for the furtherance of the work of grace in his soul. The last of these relates chiefly to the constitution and duties of the Christian church, and has been already sufficiently considered in this work. See EPISCOPACY, INDEPENDENTS, METHODISTS, PRESBYTERIANS, POPE, QUAKERS, &c. BAPTISM, EUCHARIST, &c.

Of the other three parts we shall here present our readers with a concise view of the leading particulars.

PART I.—DOCTRINES RESPECTING GOD.

SECT. I. *Of the Divine Existence.*

IN every system of theology the first truths to be believed are those which relate to the being and attributes of God. The Jewish lawgiver, therefore, who records the earliest revelations that were made to man, begins his history with a display of the power and wisdom of God in the creation of the world. He does not inform his countrymen, and expect them to believe, on the authority of his divine commission, that God *exists;* for he well knew that the being of God must be admitted, and just notions entertained of his attributes, before man can be required to pay any regard to miracles which afford the only evidence of a primary revelation. "In the beginning," says he, "God created the heavens and the earth." Here the being of God is assumed as a truth universally received; but the sentence, short as it is, reveals another, which, as we shall afterwards shew, human reason could never have discovered.

The evidence of the Divine existence is drawn partly from the intimations of conscience within us, and partly from the marks of adaptation and design in the world around us. The conviction that, apart from any human influence whatever, we are *obliged* to do one thing and to refrain from doing another, and the accompanying sense of *responsibility* which attaches to us in regard to all parts of our conduct, lead us directly to the assurance that there exists for us an *Obliger* and a *Judge.*[c] So also the obvious adaptation of the world, both as a whole and in its separate parts, to certain definite and ascertainable ends, constrains us to admit the conclusion that it must be the product of some great, wise, and powerful being, whom we call God.[d] Other modes of proof, such as the ontological one of Des Cartes, and Clarke's *a priori* one, have been adopted and advanced by philosophical theists, but their argumentative value is more than questionable.[e]

SECT. II. *Of the Divine Unity.*

As the marks of design in the universe convince us that it is the work of divine power, so the perfect harmony which pervades the universe evinces that that power is the property of *one* intelligence. That on this globe the several elements serve for nourishment to plants, plants to the inferior animals, and animals to man; that the other planets of our system are probably inhabited, and their inhabitants nourished in the same or a similar manner; that the sun is so placed as to give light and heat to all, and by the law of gravitation to bind the whole planets into one system with itself—are truths so obvious and so universally acknowledged, as to supersede the necessity of establishing them by proof. The fair inference therefore is, that the solar system and all its parts are under the government of *one intelligence*, which directs all its motions and all the changes which take place among its parts for some wise purposes. To suppose it under the government of two or more intelligences would be highly unreasonable; for if these intelligences had equal power, equal wisdom, and the same designs, one of them would evidently be superfluous; and if they had equal power and contrary designs, they could not be the parents of that harmony which we clearly perceive to prevail in the system.

The truth thus intimated by the harmony of nature is plainly and frequently asserted in the scriptures. The texts affirming this great and fundamental truth are almost numberless. "Unto thee," says Moses to his countrymen, (Deut. iv. 35 and 39; vi. 4), "it was shewed, that thou mightest know that the Lord is God; there is *none else besides him.* Know therefore that the Lord *he is God* in *heaven above* and upon the *earth beneath: there is none else.*" And again, "Hear, O Israel, the Lord our God is *one Lord*," or, as it is expressed in the original, "Jehovah our God is one Jehovah," one Being to whom existence is essential, who could not have a beginning and cannot have an end. In the prophecies of Isaiah, God is introduced as repeatedly declaring the same truth. (Isa. xiv. 5, 6, 18; xliv. 8.) In perfect harmony with these declarations of Moses and the prophets, our Saviour, addressing himself to his Father, says, (John xvii. 3), "This is life eternal, that they might know *Thee, the only true God*, and Jesus Christ whom Thou hast sent;" and St. Paul, who derived his doctrine from his divine Master, affirms, (1 Cor. viii. 4), that "an idol is nothing in the world; and that there is *none other God but one.*"

The unity of the divine nature, which, from the order and harmony of the world, appears probable to human reason, these texts of revelation put beyond a doubt. Hence the first precept of the Jewish law, and, according to their own writers, the foundation of their whole religion, was, "Thou shalt have none other gods before Me." Hence, too, the reason of that strict command to Jews and Christians to give worship to none but God: "Thou shalt worship the Lord thy God, and him only shalt thou serve;" because he is *God alone.* Him only must we fear, because he alone hath infinite power; in him alone must we trust, because "he only is our rock and our salvation;" and to him alone must we direct our devotions, because "he only knoweth the hearts of the children of men."

---

[c] The principal supporter of this moral proof (as it has been called) of the Divine existence, is Kant, who has urged it in several of his works. See his *Kritik der reinen Vernunft*, s. 223; and his *Krit. der Urtheilskraft*, s. 426. Part of the latter passage is given by Storr in his "Biblical Theology," (translated by S. S. Schmucker, D.D. Lond. 1839.)

[d] This argument is admirably developed by Paley in his Natural Theology, and fully illustrated by the authors of the Bridgewater Treatises.

[e] Vide Cartesii *Meditationes de Prima Philosophia*, Med. 3 et 5. Leibnitii *Opera Theologica*, tom. i. p. 5, &c. (Ed. Dutens. Genev. 1768.) Clarke's Demonstration of the Being and Attributes of God. Brougham's Discourse on Natural Theology, p. 81, &c. Gillespie's Necessary Existence of Deity.

SECT. III. *Of the Divine Trinity.*

It has been already remarked, on the first verse of the first chapter of Genesis, that it contains an intimation of one of the peculiar doctrines of Christianity, which human reason never could have gathered from the light of nature. That doctrine is the existence of a threefold plurality in the one Godhead. This is intimated in the passage referred to, by the use of the word אלהים, *elohim, gods,* in conjunction with a singular verb. Some indeed have gone the length of asserting, that from this the doctrine of the Trinity may be *proved;* but to this opinion we can by no means give our assent. That there are three distinct persons in the one divine nature may be inferred with sufficient evidence from a multitude of passages in the Old and New Testaments diligently compared together; but it would perhaps be rash to rest the proof of so sublime a mystery on any single text of holy scripture, and would certainly be so to rest it on the text in question. That Moses was acquainted with this doctrine, we may reasonably conclude from his so frequently making a plural name of God to agree with a verb in the singular number; but had we not possessed the brighter light of the New Testament to guide us, we should never have thought of drawing such an inference. For supposing the word אלהים to denote clearly a plurality of persons, how could we have known that the number is neither more nor less than three, had it not been ascertained to us by subsequent revelations?

There are indeed various passages in the Old Testament, of the phraseology of which no rational account can be given, but that they indicate more than one person in the Godhead. Such are those texts already noticed; "and the Lord God said, let US make man in OUR own image, after OUR likeness;" and "the Lord God said, behold the man is become like ONE of US." To these may be added the following, which are to us perfectly unintelligible on any other supposition; and "the Lord God said, let US go down, and there confound their language," (Gen. xi. 6, 7.) "If I be a *Master* (in the Hebrew *adonim,* MASTERS,) where is my fear?" (Mal. i. 6.) "The fear of the Lord (JEHOVAH) is the beginning of wisdom, and the knowledge of the Holy (in the Hebrew HOLY ONES) is understanding," (Prov. ix. 10). "Remember thy Creator (Hebrew, thy CREATORS) in the days of thy youth," (Eccles. xii. 1). "And now the LORD GOD and his SPIRIT hath sent me," (Isa. xlviii. 16.) "Seek ye out of the book of the LORD and read, for MY mouth it hath commanded, and his SPIRIT it hath gathered them," (Isa. xxxiv. 16.)

That these texts imply a plurality of divine persons, seems to us incontrovertible. When Moses wrote the passage in which he represents God as saying, let us make man, "the majesty of the plural number," as it has been called, had not been adopted by earthly sovereigns; and it is obvious that the Supreme Being could not, as has been supposed, call on angels to make man; for in different places of scripture (John ix. 8; Isa. xlv. *passim*) creation is attributed to God alone. Hence it is that Solomon speaks of Creators in the *plural number,* though he means only the one Supreme Being, and exhorts men to remember them in the days of their youth. In the passage first quoted from Isaiah, there is a distinction made between the *Lord God* and his *Spirit;* and in the other, three divine persons are introduced, viz. the *Speaker,* the *Lord,* and the *Spirit* of the Lord. It does not, however, appear evident from these passages, or from any other that we recollect in the Old Testament, that the persons in Deity are three and no more: but no sober Christian will harbour a doubt but that the precise number was by some means or other made known to the ancient Hebrews; for inquiries leading to it would be naturally suggested by the form in which the high priest was commanded to bless the people. "The LORD bless thee and keep thee. The LORD make his face to shine upon thee, and be gracious unto thee. The LORD lift up his countenance upon thee, and give thee peace," (Numb. vi. 24, 25, 26.)

The form of Christian baptism establishes the truth of the doctrine of the Trinity beyond all reasonable ground of dispute. "Go," says our blessed Saviour, "and teach all nations, baptizing them in the name of the Father, and of the Son, and of the Holy Ghost." What was it the apostles were to teach all nations? Was it not to turn from their vanities to the living God; to renounce their idols and false gods, and so to be baptized in the name of the Father, and of the Son, and of the Holy Ghost? What now must occur to the Gentile nations on this occasion, but that, instead of all their deities, to whom they had before bowed down, they were in future to serve, worship, and adore, Father, Son, and Holy Ghost, as the only true and living God? To suppose that GOD and TWO CREATURES are here joined together in the solemn rite by which men were to be admitted into a new religion, which directly condemns all *creature-worship,* would be so unreasonable, that we are persuaded such a supposition never was made by any converted polytheist of antiquity. The nations were to be baptized in the name of three persons, in the *same manner,* and therefore, doubtless, in the *same sense.* It is not said in the name of GOD and his two faithful *servants;* nor in the name of GOD, and CHRIST, and the HOLY GHOST, which might have suggested a thought that *one* only of the three is God; but in the name of the FATHER, and of the SON, and of the HOLY GHOST. Whatever honour, reverence, or regard, is paid to the first person in this solemn rite, the same is paid to all three. Is he acknowledged as the object of worship? So are the other two likewise. Is he God and Lord over us? So are they. Are we enrolled as subjects, servants, and soldiers, under him? So are we equally under all. Are we hereby regenerated and made the temple of the Father? So are we likewise of the Son and Holy Ghost. "We will come," says our Saviour, "and make our abode with him," (John xiv. 23.)

If those who believe the inspiration of the scriptures could require any further proof that the Godhead comprehends a trinity of persons in one nature, we might urge the apostolical form of benediction; "The grace of our LORD JESUS CHRIST, and the love of GOD, and the communion of the HOLY GHOST, be with you all," (2 Cor. xiii. 14.) Would St. Paul, or any other man of common sense, have in the same sentence, and in the most solemn manner, recommended his Corinthian converts to the love of God, and to the grace and communion of two creatures? We should think it very absurd to recommend a man at once to the favour of a king and a beggar; but how infinitely small is the distance between the greatest earthly potentate and the meanest beggar, when compared with that which must for ever subsist between the Almighty Creator of heaven and earth and the most elevated creature?

But how, it will be asked, can three divine persons be but one and the same God? This is a question which has been often put, but which, we believe, no created being can fully answer. It is to be observed, however, that no intelligent Trinitarians affirm that these divine Persons, or Hypostases, are *one* and *three* in the *same* sense; for this would be a contradiction in terms. What is affirmed is, that in one sense they are three, and in another one; though how this is, or what may be the difference between the one sense and the other, we are utterly unable to tell. The case is one which admits of no explanation. The divine nature and its manner of existence is, to us, wholly incomprehensible; and we might with greater reason attempt to weigh the mountains in scales, than by our limited faculties to fathom the depths of infinity. The Supreme Being is present in power to every portion of space, and yet it is demonstrable, that in his essence he is not extended, (see METAPHYSICS, p. 699.) Both these truths, his inextension and omnipresence, are fundamental principles in what is called *natural religion;* and when taken together they form, in the opinion of most people, a mystery as incomprehensible as that of the Trinity in unity. Indeed there is nothing of which it is more difficult to form a distinct notion than *unity* simple, and absolutely indivisible. Though the Trinity in unity, therefore, were no Christian doctrine, mysteries must still be believed; for they are as inseparable from the religion of nature as from that of revelation; and atheism involves the most incomprehensible of all mysteries, even the beginning of existence without a cause. We must indeed form the best notions that we can of this and all other mysteries; for if we have no notions whatever of a Trinity in unity, we can neither believe nor disbelieve that doctrine. It is however to be remembered, that all our notions of God are more or less analogical; that they must be expressed in words which, literally interpreted, are applicable only to man; and that propositions understood in this literal sense may involve an apparent contradiction, from which the truth meant to be expressed by them would be seen to be free, had we direct and adequate conceptions of the divine nature. On this account it is to be wished that men treating of the mystery of the Holy Trinity, had always expressed themselves in scripture language, and never aimed at being wise above what is written; as all attempts to explain or simplify this doctrine have proved singularly futile, ending either in pompous absurdity, or in a virtual negation of the doctrine to be explained.

Obs. 1. An attempt has been made by some of the opponents of this doctrine to represent it as borrowed by the early Christians from the speculations of the later Platonists. But if this be the case, we may properly ask, whence had those Platonists the doctrine themselves? It is not surely so simple or so obvious as to be likely to have occurred to the reasoning mind of a Pagan philosopher; or if it be, why do Unitarians suppose it to involve a contradiction? Plato indeed taught a doctrine in some respects similar to that of the Christian Trinity, and so did Pythagoras, with many other philosophers of Greece and the East; but though these sages appear to have been on some occasions extremely credulous, and on others to have indulged themselves in the most mysterious speculations, there is no room to suppose that they were *naturally weaker men* than ourselves, or that they were capable of inculcating as truths what they *perceived* to involve a *contradiction.* The Platonic and Pythagorean trinities never could have occurred to the mind of him who merely from the works of creation endeavoured to discover the being and attributes of the Creator; and therefore as those philosophers travelled into Egypt and the East in quest of knowledge, it appears to us in the highest degree probable, that they picked up this mysterious and sublime doctrine in those regions where it had been handed down as a dogma from the remotest ages, and where we know that science was not taught systematically, but detailed in collections of sententious maxims and traditionary opinions. If this be so, we cannot doubt but that the Pagan trinities had their origin in some primæval revelation. Nothing else indeed can account for the general prevalence of a doctrine so remote from human imagination, and of which we find vestiges in the sacred books of almost every civilized people of antiquity. The corrupt state in which it is viewed in the writings of Plato and others, is the natural consequence of its descent through a long course of oral tradition; and then falling into the hands of men who bent every opinion as much as possible to a conformity with their own speculations. The trinity of Platonism therefore, instead of being an objection, lends, in our opinion, no feeble support to the Christian doctrine, since it affords almost a complete proof of that doctrine's having made part of the first revelations communicated to man.

Obs. 2. See Pearson on the Creed; Burnet's Exposition of the Thirty-nine Articles; Wardlaw's Discourses on the Socinian Controversy; Stuart's Letters to Dr. Channing; Horsley's Letters to Priestley; Fuller's Works, vol. i. and vol. iv.; Waterland's Importance of the Doctrine of the Holy Trinity asserted; Faber's Apostolicity of Trinitarianism.

SECT. IV. *Of the Manifestation of Deity in the Works of Creation and Providence.*

The essence of this self-existent, all-powerful, infinitely wise, and perfectly good Being, is to us wholly incomprehensible. That it is not matter, is shown by the process of argumentation by which we have proved it to exist: but what it is we know not, and it would be impious presumption to inquire. It is sufficient for all the purposes of religion to know that God has formed all things, and is somehow or other present to every part of his work; that existence and every possible perfection is essential to him; and that he wishes the happiness of all his creatures. That he is the former of all things is explicitly stated in Scripture, as in many places, so especially in the first sentence of Genesis already quoted. That by "the heavens and the earth," in that passage, is meant the whole universe, visible and invisible, is known to every person acquainted with the phraseology of Scripture; and we need inform no man conversant with English writers, that by *creation,* in its proper sense, is meant bringing into *being* or making that to *exist* which existed not *before.* It must, however, be acknowledged, that the Hebrew word ברא does not always imply the production of substance, but very often the forming of particular organized bodies out of pre-existing matter. Thus when it is said, (Gen. i. 21, 27), that "God *created* great whales, and every living creature that moveth, which the waters brought forth abundantly after their kind," and again, "that he *created* man male and female;" though the word ברא is used on both occasions, we are not to conceive that the bodies of the first human pair, and of these animals, were brought into being from nonentity, but only that they were formed by a proper organization being given to pre-existent matter. But when Moses says, "In the beginning God *created* the heaven and the earth," he cannot be supposed to mean, that "in the beginning God only gave form to matter already existing of itself;" for in the very next verse we are assured that after this act of creation was over, "the earth was still *without form* and void," or in other words, in a chaotic state.

That the Jews, before the coming of our Saviour, understood their lawgiver to teach a proper creation, is plain from that passage in the second book of the Maccabees, in which a mother, to persuade her son to suffer the cruellest tortures rather than forsake the law of his God, uses the following argument: "I beseech thee, my son, look upon the heaven and the earth, and all that is therein, and consider that God made them of things that were not." To the same purpose the inspired author of the epistle to the Hebrews, when magnifying the excellence of faith, says, "Through faith we understand that the worlds were framed by the word of God, so that things which are seen were not made of things which do appear;" where, as Bishop Pearson has ably proved, (Exposition of the Creed), the phrase *μη ἐκφαινομενων* is equivalent to *ὀυκ ἐξ ὀντων,* in the quotation from the Maccabees.

The very first verse, therefore, of the book of Genesis informs us of a most important truth, which all the uninspired wisdom of antiquity could not discover. It assures us, that as nothing exists by chance, so nothing is necessarily existing but the three divine persons in the one Godhead. Every thing else, whether material or immaterial, derives its substance, as well as its form or qualities, from the fiat of that self-existent Being, "who was, and is, and is to come."

It does not, however, follow from this verse, or from any other passage in the sacred Scriptures, that the whole universe was called into existence at the same instant; neither is it by any means evident that the chaos of our world was brought into being on the first of those six days during which it was gradually reduced into form. From a passage in the book of Job, (xxxviii. 7), in which we are told by God himself, that when the " foundation of the earth was laid the morning stars sang together, and all the sons of God shouted for joy," it appears extremely probable that worlds had been created, formed, and inhabited, long before our earth had any existence. Nor is this opinion at all contrary to what Moses says of the creation of the stars; for though they are mentioned in the same verse with the sun and moon, yet the manner in which, according to the original, they are introduced, by no means indicates that all the stars were formed at the same time with the luminaries of our system. Most of them have been created long before, and some of them since, our world was brought into being; for that clause, (ver. 16.), " he made the stars also," is in the Hebrew no more than " and the stars;" the words *he made* being inserted by the translators. The word *verse* therefore ought to be rendered thus, " and God made two great lights; the greater light to rule the day, and the lesser light with the stars to rule the night;" where nothing is intimated with respect to the *time* when the stars were formed, any more than in that verse of the Psalms, (cxxxvi. 9), which exhorts us to give thanks to God who made the moon and stars to rule by night; for his mercy endureth " for ever." The first verse of the book of Genesis informs us that all things spiritual and corporeal derive their existence from God; but it is nowhere said that all matter was created at the same time.[1]

That the whole corporeal universe *may have been* created at once, must be granted; but if so, we have reason to believe that this earth, with the sun and all the planets of the system, were suffered to remain for ages in a state of chaos, " without form and void;" because it appears from other scriptures, that worlds of intelligent creatures existed, and even that some angels had fallen from a state of happiness, prior to the era of the Mosaic cosmogony. That the sun and the other planets revolving round him were formed at the same time with the earth, may be confidently asserted; for it is not only probable in itself from the known laws of nature, but is expressly affirmed by the sacred historian, who relates the formation of the sun and moon in the order in which it took place.

Obs. There is one part of the Mosaic narrative of the creation which requires to be more particularly noticed, as it has afforded considerable difficulty to some, and has been laid hold of by others, as invalidating the claims of the writer to divine superintendence. It is that in which he informs us, that on the *first day* after the production of the chaos, the *element of light* was created; and yet within a few sentences he declares, that the sun, the fountain of light, was not made till the *fourth day*. How are these two passages to be reconciled? We answer, that they may be reconciled many ways. Moses wrote for the use of a whole people, and not for the amusement or instruction of a few astronomers; and in this view his language is sufficiently proper, even though we suppose the formation of the sun and the other planets to have been carried on at the same time, and in the same progressive manner, with the formation of this earth. The voice which called light into existence would separate the fiery and luminous particles of the chaos from those which were opaque, and, on this hypothesis, consolidate them in one globe, diffusing an obscure light through the planetary system; but if the earth's atmosphere continued till the fourth day loaded with vapours, as from the narrative of Moses it appears to have done, the sun could not till *that day* have been *seen* from the earth, and may therefore, in popular language, be said with sufficient propriety to have been *formed* on the fourth day, as it was then made to *appear*. But though this solution of the difficulty serves to remove the objection, and to secure the credit of the sacred historian, candour compels us to confess that it appears not to be the true solution.

The difficulty itself arises entirely from supposing the sun to be the sole fountain of light; but the truth of this opinion is not self-evident, nor has it ever been established by satisfactory proof. It is indeed to a mind divested of undue deference to great names, and considering the matter with impartiality, an opinion extremely improbable. The light of a candle placed on an eminence may in a dark night be seen in every direction at the distance of at least three miles. But if this small body be rendered visible by means of rays emitted from itself, the flame of a candle, which cannot be supposed more than an inch in diameter, must, during every instant that it continues to burn, throw from its own substance luminous matter sufficient to fill a spherical space of six miles in diameter. This phenomenon, if real, is certainly surprising; but if we pursue the reflection a little farther, our wonder will be greatly increased. The matter which, when converted into flame, is an inch in diameter, is not, when of the consistence of cotton and tallow, of the dimensions of the 20th part of an inch; and therefore, on the common hypothesis, the 20th part of an inch of tallow may be so rarefied as to fill a space of 113.0976 cubic miles! a rarefaction which to us appears altogether incredible. We have indeed heard much of the divisibility of matter *ad infinitum*, and think we understand what are usually called *demonstrations* of the truth of that proposition; but these demonstrations prove not the actual divisibility of real solid substances, but only that on trial we shall find no end of the ideal process of dividing and subdividing imaginary extension.

On the whole, therefore, we are much more inclined to believe that the matter of light is an extremely subtile fluid, diffused through the corporeal universe, and only excited to agency by the sun and other fiery bodies, than that it consists of streams continually issuing from the substance of these bodies. It is indeed an opinion pretty generally received, and certainly not improbable in itself, that light and electricity are one and the same substance; but we know that the electrical fluid, though pervading the whole of corporeal nature, and, as experiments show, capable of acting with great violence, yet lies dormant and unperceived till its agency be excited by some foreign cause. Just so it may be with the matter of light. That substance may be " diffused from one end of the creation to the other. It may traverse the whole universe, form a communication between the most remote spheres, penetrate into the inmost recesses of the earth, and only wait to be put in a proper motion to communicate visible sensations to the eye. Light is to the organ of sight what the air is to the organ of hearing. Air is the medium which, vibrating on the ear, causes the sensation of sound; but it equally exists round us at all times, though there be no sonorous body to put it in motion. In like manner, light may be equally extended at all times, by night as well as by day, from the most distant fixed stars to this earth, though it then only strikes our eyes so as to excite visible sensations when impelled by the sun or some other mass of fire." Nor let any one imagine that this hypothesis interferes with any of the known laws of optics; for if the rays of light be impelled in straight lines, and in the same direction in which they are supposed to be emitted, the phenomena of vision must necessarily be the same.

Moses therefore was probably a more accurate philosopher than he is sometimes represented. The element of light was doubtless created, as he informs us, on the first day; but whether it was then put in that state in which it is the medium of vision, we cannot know, and we need not inquire, since there was neither man nor inferior animal with organs fitted to receive its impressions. For the first three days it may have been used only as a powerful instrument to reduce into order the jarring chaos. Or if it was from the beginning capable of communicating visible sensations, and dividing the day from the night, its agency must have been immediately excited by the Divine power till the fourth day, when the sun was formed, and endowed with proper qualities for instrumentally discharging that office. This was indeed miraculous, as being contrary to the present laws of nature: but the whole creation was miraculous; and we surely need not hesitate to admit a less miracle where we are under the necessity of admitting a greater. The power which called light and all other things into existence, could give them their proper motions by ten thousand different means; and to attempt to solve the difficulties of creation by philosophic theories respecting the laws of nature, is to trifle with the common sense of mankind: it is to consider as subservient to a law that very power by whose continued exertion the law is established.

The Scriptures inform us that creation was the work of the Trinity. Moses declares that the heaven and the earth were created, not by *one* person, but by the *Elohim*. The λογος indeed, or second person, appears to have been the

---

[1] See Lectures " On the Relation between the Holy Scriptures and some parts of Geological Science." By J. P. Smith, D.D. Lect. vii. part ii. Lond. 1839, 8vo.

immediate Creator; for St. John assures us, (chap. i. 3), that "all things were made by him, and that without him was not any thing made that was made." Some Arian writers of great learning (and we believe the late Dr. Price was of the number) have asserted, that a being who was created himself may be endowed by the Omnipotent God with the power of creating other beings; and as they hold the λογος or *word*, to be a creature, they contend that he was employed by the Supreme Deity to create, not the whole universe, but only this earth, or at the utmost the solar system. "The old argument," says one of them, "that no being inferior to the great Omnipotent can create a world, is so childish as to deserve no answer. Why may not God communicate the power of making worlds to any being whom he may choose to honour with so glorious a prerogative? I have no doubt but such a power may be communicated to many good men during the progress of their existence; and to say that it may *not*, is not only to limit the power of God, but to contradict acknowledged analogies."

We are far from being inclined to limit the power of God. He can certainly do whatever involves not a direct contradiction; and therefore, though we know nothing *analogous* to the power of *creating worlds*, yet as we perceive not any contradiction implied in the notion of that power being communicated, we shall admit that such a communication may be *possible*, though we think it in the highest degree *improbable*. But surely no man will contend that the *whole universe* was brought into existence by *any creature;* because that creature himself, however highly exalted, is necessarily comprehended in the notion of the universe. Now St. Paul expressly affirms (Colos. i. 17) that, by the second person in the blessed Trinity, "were ALL *things* created that are in heaven, and that are in earth, *visible* and *invisible*, whether they be THRONES, or DOMINIONS, or PRINCIPALITIES, or POWERS; all things were created by him and for him; and he is before all things, and by him all things consist." Indeed the Hebrew Scriptures in more places than one (Isa. xl. 12; xliv. 24. Jer. x. 10–13) expressly declare that this earth, and of course the whole solar system, was *formed*, as well as *created*, not by an inferior being, but by the *true* God, even *Jehovah* alone; and in the New Testament, (Rom. i. 18–22), the Gentiles are said to be without excuse for not glorifying him as God, "because his eternal power and Godhead are clearly seen from the creation of the world." But if it were natural to suppose that the power of creating worlds has been, or ever will be, communicated to beings inferior to the great Omnipotent, this reasoning of the apostle's would be founded on false principles, and the sentence which he passed on the Heathen would be contrary to justice.

But though it be thus evident that the λογος was the immediate Creator of the universe, we are not to suppose that it was without the concurrence of the other two persons. The Father, who may be said to be the fountain of the Divinity itself, was certainly concerned in the creation of the world, and is therefore in the apostle's creed denominated the "Father Almighty Maker of heaven and earth;" and that the Holy Ghost or third person is likewise a Creator, we have the express testimony of two inspired writers: "By the word of the Lord (says the Psalmist) were the heavens made, and all the host of them by the breath (Hebrew, SPIRIT) of his mouth." And Job declares, that the "SPIRIT of God made him, and that the breath of the Almighty gave him life." Indeed these three divine persons are so intimately united, that what is done by one must be done by all, as they have but one and the same will. This is the reason assigned by Origen (*Contra Cels.* p. 386) for our paying divine worship to each; *θρησκευομεν ὀυν τον πατερα της ἀληθειας, και τον ὑιον την ἀληθειαν, ὀντα δυο τῃ ὑποστασει πραγματα, ἑν δε τῃ ὁμονοιᾳ, και τῃ συμφωνιᾳ, και τῃ ταυτοτητι της βουλησεως.* "We worship the Father of truth, and the Son the truth itself, being two things as to hypostasis, but one in agreement, consent, and sameness of will." Nor is their union a mere agreement in will only; it is a physical or essential union: so that what is done by one must necessarily be done by the others also, according to that of our Saviour, "I am in the Father and the Father in me: The Father who dwelleth in me, he doth the works."

Over the universe thus framed by him the Deity presides with watchful providence and care, attending to the minutest circumstance, and regulating the course of every event. Comp. Psal. xviii. 31; xxxvi. 6–15. Matt. vi. 25–32; x. 29. John v. 17. Acts xvii. 24, &c. See also Art. PROVIDENCE and PREDESTINATION in this work.

SECT. V. *Of the Divine Attributes.*

From the phenomena of nature and the statements of Scripture we not only learn that God exists, but also that he is possessed of certain qualities, intellectual and moral, by which he becomes known to his creatures. Of these some are announced by both nature and Scripture; for our knowledge of others we are indebted to Scripture alone. In the present outline it seems necessary to mention only the following:

i. *Power.* How strongly do the works of creation impress on our minds a conviction of the infinite power of their Author! He spoke, and the universe started into being; he commanded, and it stood fast. How mighty is the arm which "stretched out the heavens and laid the foundations of the earth; which removeth the mountains and they know it not; which overturneth them in his anger; which shaketh the earth out of her place, and the pillars thereof tremble! How powerful the word which commandeth the sun, and it riseth not; and which sealeth up the stars;" which sustaineth numberless worlds of amazing bulk suspended in the regions of empty space, and directs their various and inconceivably rapid motions with the utmost regularity! "Lift up your eyes on high, and behold, who hath created all these things? By the word of the Lord were the heavens made, and all the host of them by the breath of his mouth. Hell is naked before him, and destruction hath no covering. He stretcheth out the north over the empty place, and hangeth the earth upon nothing. He has measured the waters in the hollow of his hand, and meted out the heavens with a span; and comprehended the dust of the earth in a measure: and weighed the mountains in scales, and the hills in a balance. Behold! the nations are as a drop of the bucket, and are counted as the small dust of the balance; behold, he taketh up the isles as a very little thing. All nations before him are as nothing, and they are counted to him less than nothing and vanity. To whom then will ye liken God, or what likeness will ye compare unto him?" Ps. xxxiii. 6, 9. Job ix. 4, &.; xxvi. 6. Isa. xl. 12.

ii. *Wisdom.* As the works of creation are the effects of God's power, they likewise, in the most eminent manner, display his wisdom. This was so apparent to Cicero, even from the partial knowledge in astronomy which his time afforded, that he declared (De Nat. Deorum, lib. ii.) those who could assert the contrary to be void of all understanding. But if that great master of reason had been acquainted with the modern discoveries in astronomy, which exhibit numberless worlds scattered through space, and each of immense magnitude; had he known that the sun is placed in the centre of our system, and that, to diversify the seasons, the planets move round him with exquisite regularity; could he have conceived that the distinction between light and darkness is produced by the diurnal rotation of the earth on its own axis, instead of that disproportionate whirling of the whole heavens which the ancient astronomers were forced to suppose; had he known of the wonderful motions of the comets, and considered how such eccentric bodies have been preserved from falling upon some of the planets in the same system, and the several systems from falling upon each other; had he taken into the account that there are greater things than these, and "that we have seen but a few of God's works;" that virtuous pagan would have been ready to exclaim in the words of the Psalmist, "O Lord, how manifold are thy works! In wisdom hast thou made them all; the earth is full of thy riches."

In the attribute of infinite wisdom is comprehended that of *omniscience;* for as wisdom is only knowledge well-directed, *perfect* wisdom must be the well-directing of *all* knowledge.

iii. *Goodness.* The goodness of God is not less conspicuous in his works than His power or His wisdom. Contrivance proves design, and the predominant tendency of the contrivances indicates the disposition of the designer.

Now, all the evidences of design which we behold in the universe are directed to useful and beneficial purposes, and, consequently, indicate benevolence as a predominating feature in the character of the Creator; while, from the vast number of creatures on our earth endowed with life and sense, and a capability of happiness, and the infinitely greater number which probably inhabit the planets of this and other systems, we may infer that the goodness of God is as boundless as his power, and that "as is his majesty, so is his mercy." Out of his own fulness hath he brought into being numberless worlds, replenished with myriads of myriads of creatures, furnished with various powers and organs, capacities and instincts; and out of his own fulness he continually and plentifully supplies them all with every thing necessary to make their existence comfortable. "The eyes of all wait upon him, and he giveth them their meat in due season. He openeth his hand and satisfies the desires of every living thing; he loveth righteousness and judgment; the earth is full of the goodness of the Lord. He watereth the ridges thereof abundantly; he settleth the furrows thereof; he maketh it soft with showers, and blesseth the springing thereof. He crowneth the year with his goodness; and his paths drop fatness. They drop upon the pastures of the wilderness; and the little hills rejoice on every side. The pastures are clothed with flocks; the valleys also are covered with corn; they shout with joy, they also sing." Survey the whole of what may be seen on and about this terraqueous globe, and say, if our Maker has a sparing hand. Surely the Author of so much happiness must be essential goodness; and we must conclude with St. John, that "God is love."

Obs. "The world abounds with contrivances, and all the contrivances in it with which we are acquainted are directed to beneficial purposes. Evil no doubt exists; but it is never, that we can perceive, the object of contrivance. Teeth are contrived to eat, not to ache; their aching now and then is incidental to the contrivance, perhaps inseparable from it: but it is not its object. This is a distinction which well deserves to be attended to. In describing implements of husbandry, one would hardly say of a sickle that it is made to cut the reaper's fingers, though, from the construction of the instrument, and the manner of using it, this mischief often happens. But if he had occasion to describe instruments of torture or execution, this, he would say, is to extend the sinews; this to dislocate the joints; this to break the bones; this to scorch the soles of the feet. Here pain and misery are the very objects of the contrivance. Now, nothing of this sort is to be found in the works of nature. We never discover a train of contrivance to bring about an evil purpose. No anatomist ever discovered a system of organization calculated to produce pain and disease; or, in explaining the parts of the human body, ever said, this is to irritate, this to inflame, this duct is to convey the gravel to the kidneys, this gland to secret the humour which forms the gout. If, by chance, he came to a part of which he knows not the use, the most that he can say is, that to him it appears to be useless: no one ever suspects that it is put there to incommode, to annoy, or to torment. If God had wished our misery, he might have made sure of his purpose, by forming our senses to be as many sores and pains to us as they are now instruments of gratification and enjoyment; or, by placing us among objects so ill suited to our perceptions as to have continually offended us, instead of ministering to our refreshment and delight. He might have made, for instance, every thing we tasted bitter, every thing we saw loathsome, every thing we touched a sting, every smell a stench, and every sound a discord."—*Paley's Natural Theology.*

Instead of this, all our sensations, except such as are excited by what is dangerous to our health, are pleasures to us. The view of a landscape is pleasant; the taste of nourishing food is pleasant; sounds not too loud are agreeable, while musical sounds are exquisite; and scarcely any smells, except such as are excited by effluvia obviously pernicious to the brain, are disagreeable; while some of them, if not too long indulged, are delightful. Since, then, God has called forth his consummate wisdom to contrive and provide for our happiness, and has made those things, which are necessary to our existence, sources of pleasure to us; who can doubt but that benevolence is one of his attributes; and that, if it were not impious to draw a comparison between them, it is the attribute in which he himself most delighteth?

But it is not from sensation only that we may infer the benevolence of the Deity. He has formed us with minds capable of intellectual improvement, and he has implanted in the breast of every man a very strong desire of adding to his knowledge. This addition, it is true, cannot be made without labour; and, at first, the requisite labour is to most people irksome: but a very short progress in any study converts what was irksome into a pleasure of the most exalted kind; and he who by study, however intense, enlarges his ideas, experiences a complacency, which, though not so poignant, perhaps, as the pleasures of the sensualist, is such as endears him to himself, and is what he would not exchange for any thing else which this world has to bestow, except the still sweeter complacency arising from the consciousness of having discharged his duty.

That the practice of virtue is attended with a peculiar pleasure of the purest kind, is a fact which no man has ever questioned, though the immediate source of that pleasure has been the subject of many disputes. He who attributes it to a moral sense, which instinctively points out to every man his duty, and on the performance of it rewards him with a sentiment of self-approbation, must of necesssity acknowledge benevolence to be one of the attributes of that Being who has so constituted the human mind. That to protect the innocent, relieve the distressed, and do to others as we would in like circumstances wish to be done by, fills the breast, previously to all reflection, with a holy joy, as the commission of any crime tears it with remorse, cannot indeed be controverted. Many, however, contend, that this joy and this remorse spring not from any moral instinct implanted in the mind, but are the consequence of early and deep-rooted associations of the practice of virtue with the hope of future happiness, and of vice with the dread of future misery. On the respective merits of these two theories we shall not now decide, but only observe, that they both lead with equal certainty to the benevolence of the Deity, who made us capable of forming associations, and subjected those associations to fixed laws. This being the case, the moral sense, with all its instantaneous effects, affords not a more convincing proof of his goodness, than that principle in our nature by which remote circumstances become so linked together, that the one circumstance never occurs without bringing the other also into view. It is thus that the pleasing complacency, which was, perhaps, first excited by the hopes of future happiness, comes in time to be so associated with the consciousness of virtuous conduct, the only thing entitled to reward, that a man never performs a meritorious action without experiencing the most exquisite joy diffused through his mind, though his attention at that instant may not be directed either to heaven or to futurity. Were we obliged, before we could experience this joy, to estimate by reason the merit of every individual action, and trace its connection to heaven and future happiness through a long train of intermediate reasoning, we should be, in a great measure, deprived of the present reward of virtue; and, therefore, this associating principle contributes much to our happiness. But the benevolence of a Being, who seems thus anxious to furnish us with both sensual and intellectual enjoyments, and who has made our duty our greatest pleasure, cannot be questioned; and therefore we must infer, that the Author of Nature wishes the happiness of the whole sensible and intelligent creation. Ps. cxiv. 15, 16; xxiii. 5; lv. 10, &c.

Objectors have asked, Why, if the Author of Nature be a benevolent Being, are we necessarily subject to pain, diseases, and death? The scientific physiologist replies, Because, from these evils, Omnipotence itself could not in our present state exempt us, but by a constant series of miracles. He who believes the Bible, knows likewise that mankind were originally in a state in which they were not subject to death; and that they fell under its dominion through the fault of their common progenitors. Without, however, insisting upon this, the question is one which may be answered upon such data as are presented by the phenomena of nature. Now, we know that as all matter is divisible, every system composed of it must necessarily be liable to decay and dissolution; and our material system would decay and be dissolved long before it could serve the purposes of nature, were therenot methods contrived, with admirable wisdom, for repairing the waste occasioned by perpetual friction. The body is furnished with different fluids, which continually circulate through it in proper channels, and leave in their way what is necessary to repair the solids. These again are supplied by food *ab extra;* and to the whole processes of digestion, circulation, and nutrition, the air we breathe is absolutely necessary. But as the air is a very heterogeneous fluid, and subject to violent and sudden changes, it is obvious that these changes must affect the blood, and by consequence the whole frame of the human body. The air, indeed, in process of time consumes even marble itself; and, therefore, we cannot wonder that as it is in one state the parent of health, it should in another be the source of disease to such creatures as man and other terrestrial animals. Nor could these consequences be avoided without introducing others much more deplorable. The world is governed by general laws, without which there could be among men neither arts nor sciences; and though laws different from those by which the system is at present governed might, perhaps, have been established, there is not the smallest reason to imagine that they could on the whole have been better, or attended with fewer inconveniences. As long as we have material and solid bodies capable of motion, liable to resistance from other solid bodies, supported by food, subject to the agency of the air, and divisible, they must necessarily be liable to pain, disease, corruption, and death, and that, too, by the very influence of those laws which preserve the order and harmony of the universe. Thus gravitation is a general law so good and so necessary, that were it for a moment suspended, the world would instantly fall to pieces; and yet, by means of this law, the man must inevitably be crushed to death on whom a tower shall chance to tumble. Again, the attraction of cohesion is a general law, without which it does not appear that any corporeal system could possibly exist: it is by this law, too, or a modification of it, that the glands and lacteals of the human body extract from the blood such particles as are necessary to nourish the solids; and yet it is by means of the very same modification of the very same law that a man is liable to be poisoned.

Although the human body could not have been preserved from dangers and dissolution, but by introducing evils greater on the whole than those to which it is now liable, why, it has sometimes been asked, is every disorder to which it is subject attended with sickness or with pain? and why is such a horror of death implanted in our breasts, seeing that, by the laws of nature, death is inevitable? We answer, That sickness, pain, and the dread of death, serve the very best purposes. Could a man be put to death, or have his limbs broken without feeling pain, the human race had long ago been extinct. Felt we no uneasiness in a fever, we should be insensible of the disease, and die before we suspected our health to be impaired. The horror which generally accompanies our reflections on death tends to make us more careful of life, and prevents us from quitting this world rashly, when our affairs prosper not according to our wishes. It is likewise an indication that our existence does not terminate in this world; for our dread is seldom excited by the prospect of the pain which we may suffer when dying, but by our anxiety concerning what we may be doomed to suffer or enjoy in the next stage of our existence; and this anxiety tends more, perhaps, than any thing else to make us live while we are here in such a manner as to ensure our happiness hereafter.

iv. *Righteousness.* In our views of the Divine benevolence, we must not forget that it is not such a fond affection as often obtains that name among men. All human affections and passions originate in our dependence and wants; and it has been doubted whether any of them be at first disinterested: but he to whom existence is essential cannot be dependent; he who is the Author of every thing can feel no want. The Divine benevolence, therefore, must be wholly disinterested, and, of course, free from those partialities originating in self-love, which are alloys in the most sublime of human virtues. The most benevolent man on earth, though he wishes the happiness of every fellow-creature, has still, from the ties of blood, the endearments of friendship, or, perhaps, from a regard to his own interest, some particular favourites whom, on a competition with others, he would certainly prefer. But the equal Lord of all can have no particular favourites. His benevolence is therefore coincident with justice; or, that which is called *divine justice,* is only benevolence exerting itself in a particular manner for the propagation of general felicity. When God prescribes laws for regulating the conduct of his intelligent creatures, it is not because he can reap any benefit from their obedience to those laws, but because such obedience is necessary to their own happiness; and when he punishes the transgressor, it is not because, in his nature, there is any disposition to which the prospect of such punishment can afford gratification, but because, in the government of free agents, punishment is necessary to reform the criminal, and to intimidate others from committing the like crimes. Compare Ps. vii. 10–18. Rom. ii. 5, 6. 2 Tim. iv. 8. Rev. xix. 2, &c.—Intimately connected with the *righteousness* of God is his *holiness,* for we cannot but infer that he, who so earnestly desires and carefully enjoins the moral excellence of his creatures, is himself the grand pattern of all moral beauty. Compare Matt. v. 45—48. Eph. iv. 24. 1 Pet. i. 16. 2 Pet. i. 4. 1 John i. 5, &c.

v. *Immutability and Veracity.* He who is perfectly wise and holy must be unchangeable, for *change* can characterise the conduct only of beings whose faculties do not exclude the possibility of error, or whose will is liable to be influenced by unworthy motives. Hence the Scriptures ascribe to God the attribute of immutability as to his purposes, decrees, and judgments; compare Exod. iii. 14—17; vi. 2—8. Deut. vii. 8—11. Ps. xxxiii. 9—11. Matt. iii. 6. Rom. xi. 29. Heb. vi. 17, 18. James i. 17, &c. Closely connected with this is the divine Veracity; for he who never changes can never, by any subsequent word or deed, contradict what he has already said; compare Numb. xxiii. 19. Ps. xxxiii. 4. Isa. xlvi. 9, 10. Rom. iii. 3—5. 2 Cor. i. 18—20. Tit. i. 2, &c.

SECT. VI.—*Of the Reverence due to the Deity.*

From the short view that we have taken of the divine perfections, it is evidently our duty to reverence, in our minds, the self-existent Being to whom they belong. This is, indeed, not only a duty, but a duty of which no man who contemplates these perfections, and believes them to be real, can possibly avoid the performance. He who thinks irreverently of the Author of nature, can never have considered seriously the power, the wisdom, and the goodness displayed in his works; for whoever has a clear notion of these must be convinced, that he who performed them has no imperfection; that his power can accomplish every thing which involves not a contradiction; that his knowledge is intuitive, and free from the possibility of error; and that his goodness extends to all without partiality and without any alloy of selfish design. This conviction must make every man, on whose mind it is impressed, ready to prostrate himself in the dust before the Author of his being; who, though infinitely exalted above him, is the source of all his enjoyments, constantly watches over him with paternal care, and protects him from numberless dangers. The sense of so many benefits must excite in his mind a sense of the liveliest gratitude to him from whom they are received, and an ardent wish for their continuance.

While silent gratitude and devotion thus glow in the breast of the contemplative man, he will be careful not to form even a mental image of that all-perfect Being to whom they are directed. He knows that God is not material; that he exists in a manner altogether incomprehensible; that to frame an image of him would be to assign limits to what is infinite; and that to attempt to form a positive conception of him would be impiously to compare himself with his Maker.

The man who has any tolerable notion of the perfections of the Supreme Being will never speak lightly of him, or make use of his name except on great and solemn occasions. He knows that the terms of all languages are inadequate and improper, when applied directly to him who has no equal, and to whom nothing can be compared; and therefore he will employ these terms with caution. When he speaks of his mercy and compassion, he will not consider them as feelings wringing the heart like the mercy and compassion experienced by man, but as rays of pure and disinterested benevolence. When he thinks of the stupendous system of nature, and hears it perhaps said that God formed it for his own glory, he will reflect that God is so infinitely exalted above all his creatures, and so perfect in himself, that he can neither take pleasure in their applause, nor receive any accession of any kind from the existence of ten thousand worlds. The immense fabric of nature, therefore, only displays the glory or perfections of its Author to *us*, and to other *creatures* who have not faculties to comprehend him in himself.

When the contemplative man talks of *serving* God, he does not dream that his services can increase the divine felicity; but means only that it is his duty to obey the divine laws. Even the pronoun *He*, when it refers to God, cannot be of the same import as when it refers to man; and by the philosophical divine it will seldom be used but with a mental allusion to this obvious distinction.

As the man who daily venerates the Author of his being will not speak of him on trivial occasions, so will he be still further from calling upon him to witness impertinences and falsehood. (See Oath). He will never mention his name but with a *pause*, that he may have time to reflect in silence on his numberless perfections, and on the immense distance between himself and the Being of whom he is speaking. The slightest reflection will convince him that the world, with all that it contains, depends every moment on that God who formed it; and this conviction will compel him to wish for the divine protection of himself and his friends from all dangers and misfortunes. Such a wish is in effect a prayer, and will always be accompanied with adoration, confession, and thanksgiving. (See Prayer). But adoration, confessions, supplications, and thanksgiving constitute what is called *worship*, and therefore the worship of God is a natural duty. It is the addressing of ourselves as his dependants to him as the supreme cause and governor of the world, with acknowledgments of what we enjoy, and petitions for what we really want, or he knows to be convenient for us.

Obs. See Wollaston's Religion of Nature delineated.

Part II.—Doctrines concerning Man.

Sect. I.—*Of the Original State of Man.*

In the Mosaic account of the creation we are told that "God created man in his own image; in the image of God created he him; male and female created he them," Gen. i. 27. In these words we have a description of the nature of man as he came at first from the hands of his Creator, into the proper meaning of which it is of great importance that we should inquire.

The answer to this inquiry depends upon the meaning we attach to the words "in the image of God;" for it is by that phrase, that the peculiarity of man's nature, and his pre-eminence over the brutes, is marked. Now, this image or likeness must have been found either in his body alone, his soul alone, or in both united. That it could not be in his body alone, is obvious; for the infinite and omnipotent God is allowed by all men to be without body, parts, or passions, and therefore to be such as nothing corporeal can possibly resemble.

If this likeness is to be found in the human soul, it comes to be a question in what faculty or power of the soul it consists. Some have contended, that man is the only creature on this earth who is animated by a principle essentially different from matter; and hence they have inferred, that he is said to have been formed in the Divine image, on account of the immateriality of that vital principle which was infused into his body when "the Lord God breathed into his nostrils the breath of life, and man became a living soul," (Gen. ii. 7.) That this account of the animation of the body of man indicates a superiority of the human soul to the vital principle of all other animals, cannot, we think, be questioned; but it does not therefore follow, that the human soul is the only immaterial principle of life which animates any terrestrial creature. It has been shewn elsewhere (see Metaphysics), that the power of sensation, attended with individual consciousness, as it appears to be in all the higher species of animals, cannot result from any organical structure, or be the quality of a compound extended being. The vital principle in such animals, therefore, must be immaterial as well as the human soul; but as the word *immaterial* denotes only a negative notion, the souls of men and brutes, though both immaterial, may yet be substances essentially different. This being the case, it is plain that the Divine image in which man was formed, and by which he is distinguished from the brute creation, cannot consist in the mere circumstance of his mind being a substance different from matter, but in some positive quality which distinguishes him from every other creature on this globe.

About this characteristic quality various opinions have been formed. By Calvinists it is generally supposed, "that the image of God in Adam appeared in that rectitude, righteousness, and holiness, in which he was made; for God made man upright (Eccles. vii. 2), a holy and righteous creature; which holiness and righteousness were in their kind perfect; his understanding was free from all error and mistakes; his will biased to that which is good; his affections flowed in a right channel towards their proper objects; there were no sinful notions and evil thoughts in his heart, nor any propensity or inclination to that which is evil; and the whole of his conduct and behaviour was according to the will of God. And this righteousness (say they) was *natural*, and not personal and acquired. It was not obtained by the exercise of his free-will, but was created with him, and belonged to his mind, as a natural faculty or instinct." Gill's Body of Divinity, b. iii. ch. 3. They, therefore, call it *original righteousness*, and suppose that it was lost in the fall.

To this doctrine many objections have been made. It has been said that righteousness consisting in right actions proceeding from proper principles, could not be created with Adam and make a part of his nature; because nothing which is produced in a man, without his knowledge and consent, can be in him either virtue or vice. Adam, it is added, was unquestionably placed in a state of trial, which proves that he had righteous habits to *acquire;* whereas the doctrine under consideration, affirming his original righteousness to have been perfect, and therefore incapable of improvement, is inconsistent with a state of trial. That his understanding was free from all errors and mistakes, has been thought a blasphemous position, as it attributes to man one of the incommunicable perfections of the Deity. It is likewise believed to be contrary to fact; for either his understanding was bewildered in error, or his affections flowed towards an improper object, when he suffered himself, at the persuasion of his wife, to transgress the express law of his Creator. The objector expresses his wonder at its having ever been supposed that the *whole* of Adam's conduct and behaviour was according to the will of God, when it is so notorious that he yielded to the first temptation with which, as far as we know, he was assailed in Paradise.

Convinced by these and other arguments, that the image of God, in which man was created, could not consist in original righteousness, or in exemption from all possibility of error, many learned men, and Bishop Bull (English Works, vol. iii.) among others, have supposed, that by the image of God is to be understood certain gifts and powers supernaturally infused by the Holy Spirit into the minds of our first parents, to guide them in the ways of piety and virtue. This opinion they rest chiefly upon the authority of Tatian, Irenæus, Tertullian, Cyprian, Athanasius, and other fathers of the primitive church; but they think, at the same time, that it is countenanced by several passages in the New Testament. Thus when St. Paul says, (1 Cor. xv. 45, 46,) "and so it is written, the first man Adam was made a living soul, the last Adam was made a quickening spirit;" they understand the whole passage as relating to the creation of man, and not as drawing a comparsion between Adam and Christ, to show the great superiority of the latter over the former. In support of this interpretation they observe, that the apostle immediately adds, "howbeit, that was not first which is spiritual, but that which is natural, and afterwards that which is spiritual;" an addition which they think was altogether needless, if, by the quickening spirit, he had referred to the incarnation of Christ, which had happened in the very age in which he was writing. They are therefore of opinion, that the body of Adam, after being formed of the dust of the ground, was first animated by a vital principle, endowed with the faculties of reason and sensation, which entitled the whole man to the appellation of a living soul. After this, they suppose certain graces of the Holy Spirit to have been infused into him, by which he was made a quickening spirit, or formed in the image of God; and that it was in consequence of this succession of powers communicated to the same person, that the apostle said, "howbeit, that was not first which is spiritual, but that which is natural."

We need hardly observe that, with respect to a question of this kind, the authority of Tatian and the other fathers quoted is of no great weight. Those men had no better means of discovering the true sense of the scriptures of the Old Testament than we have; and their ignorance of the language in which these scriptures are written, added to some metaphysical notions respecting the soul, which too many of them had derived from the school of Plato, rendered them very ill qualified to interpret the writings of Moses. Were authority to be admitted, we should consider that of Bishop Bull and his modern followers as of greater weight than the authority of all the ancients to whom they appeal. But authority cannot be admitted; and the reasoning of this learned and excellent man, from the text of St. Paul, is surely very inconclusive. It makes two persons of Adam; a first, when he was a natural man, composed of a body and a reasonable soul; a second, when he was endowed with the gifts of the Holy Spirit, and by them formed in the image of God. In the verse following, the apostle expressly calls the second man, of whom he had been speaking, "the Lord from heaven;" but this appellation we apprehend to be too high for Adam in the state of greatest perfection in which he ever existed. That our first parents were endowed with the gifts of the Holy Ghost may be granted; but as these gifts were adventitious to their nature, they could not be that image in which God *made* man.

Since man was *made* in the image of God, that phrase, whatever be its precise import, must denote something *peculiar* and at the same time essential to human nature; but the only two qualities at once natural and peculiar to man are his *shape* and his *reason.* As none but an anthropomorphite will say that it was Adam's shape which reflected this image of his Creator, it has been concluded that it was the faculty of reason which made the resemblance. To give strength to this argument, it is observed by Warburton, (Divine Leg., book ix.) that when God says, "let us make man in our image," he immediately adds, "and let them have dominion over the fish of the sea, and over the fowl of the air, and over the cattle, and over all the earth;" but as many of the cattle have much greater bodily strength than man, this dominion could not be maintained but by the faculty of reason bestowed upon him and withheld from them.

If the image of God was impressed only on the mind of man, this reason seems to be conclusive; but it has been well observed by Gill, (Body of Divinity, book iii. chap. 3,) that it was the whole man, and not the *soul alone*, or the *body alone*, that is said to have been formed in the divine image; even as the whole man, soul and body, is the seat of the new and spiritual image of God in regeneration and sanctification "The very God of peace," says the apostle, "sanctify you wholly; and may your whole *spirit*, *soul*, and *body*, be preserved blameless to the coming of our Lord Jesus Christ." It is worthy of notice, that the reason assigned for the prohibition of murder to Noah and his sons after the deluge, is, that man was made in the image of God. "Whoso sheddeth man's blood, by man shall his blood be shed; for in the image of God made he man." These texts seem to indicate, that whatever be meant by the image of God, it was stamped equally on the soul and on the body. In vain it is said that man cannot resemble God in shape. This is true, but it is little to the purpose; for man does not resemble God in his reasoning faculty more than in his form. It would be idolatry to suppose the supreme majesty of heaven and earth to have a body or a shape; and it would be little short of idolatry to imagine that he is obliged to compare ideas and notions together; to advance from particular truths to general propositions; and to acquire knowledge, as we do, by the tedious processes of inductive and syllogistic reasoning. There can, therefore, be no direct image of God either in the soul or in the body of man; and the phrase really seems to import nothing more than those powers or qualities by which man was fitted to exercise dominion over the inferior creation; as if it had been said, "Let us make man in our image, after our likeness, that *they may have* dominion," &c. But the erect form of man contributes, in some degree, as well as his rational powers, to enable him to maintain his authority over the brute creation; for it has been observed by travellers, that the fiercest beast of prey, unless ready to perish by hunger, shrinks back from a steady look of the human face divine.

By Dr. Gill and other writers, who have admitted the probability of this interpretation, another has been devised of the expression that man was formed in the image of God. All the members of Christ's body, say they, were written and delineated in the book of God's purposes and decrees, and had an ideal existence from eternity in the divine mind; and therefore the body of Adam might be said to be formed after the image of God, because it was made according to that idea. But to this reasoning objections may be urged, which we know not how to answer. All things that ever were or ever shall be, the bodies of us who live at present, as well as the bodies of those who lived 5000 years ago, have from eternity had an ideal existence in the Divine mind; nor in this sense can one be said to be prior to another. It could not, therefore, be after the idea of the identical body of Christ that the body of Adam was formed; for in the Divine mind ideas of both bodies were present together from eternity, and each body was formed after the ideal archetype of itself. It may be added, likewise, that the body of Christ was not God, nor the idea of that body the idea of God. Adam, therefore, could not, with propriety, be said to have been formed in the image of God, if, by that phrase, nothing more were intended than the resemblance between his body and the body of Christ. These objections to this interpretation appear to us unanswerable; but we mean not to dictate to our readers. Every man will adopt that opinion which he thinks supported by the best arguments; but it is obvious, that whatever more may be meant by the image of God in which man was made, the phrase undoubtedly comprehends all those powers and qualities by which he is enabled to maintain his authority over the inferior creation. Among these the faculty of reason is confessedly the most important; for it is by it that man is capable of being made acquainted with the Author of his being, the relation which subsists between them, and the duties implied in that relation from the creature to the Creator.

SECT. II.—*Of the Religion of Man in his Primeval State.*

It is more than probable that man, after his creation, was not left to discern, by the efforts of his own unassisted reason, either his own character or the duties which devolved upon him towards God. This opinion is confirmed by what the inspired historian tells us, when he says, Gen. ii., "God blessed the seventh day and sanctified it, because that in it he had rested from all his works which he had created and made;" for Adam could not have understood what was meant by the *sanctification* of a particular day, or of any thing else, unless he had previously received some religious instruction. There cannot therefore be a doubt, but that, as soon as man was made, his Creator communicated to him the truths of what is called natural religion; and to these were added the precept to keep holy the Sabbath-day, and set it apart for the purposes of contemplation and worship.

This was a very wise institution, as all the divine institutions must be. "The great end for which we are brought into life, is to attain the knowledge and be confirmed in the love of God. This includes obedience to his will in thought, word, and deed, or that course of conduct which can alone make us happy here, and fit us for everlasting glory hereafter. But of these things we cannot retain a proper sense without close and repeated application of thought; and the unavoidable cares and concerns of the present life occupying much of our attention, it is, in the nature of things, necessary that some certain portion of time should be appropriated to the purposes of religious instruction and the public adoration of our Creator, in whom we all live, and move, and have our being." Hence a very learned divine, Dr. Taylor of Norwich, has inferred, that though the particular time is a matter of positive appointment, the observation of a sabbath, in general, is a duty of natural religion, as having its foundation in the reason of things. See SABBATH.

Man, therefore, in his *natural* and original state was a rational and religious being, bound to do "justice, to love mercy, to walk humbly with his God, and to keep holy the Sabbath-day."

In this original state, man was under the discipline of what we have called *natural religion*, entitled to happiness while he should perform the duties required of him, and liable to punishment when he should neglect those duties, or transgress the law of his nature as a rational and moral agent. This being the case, it is a matter of some importance, to ascertain, if we can, what the rewards and punishments are which natural religion holds out to her votaries.

That under every dispensation of religion the pious and virtuous man shall enjoy more happiness than misery; and that the incorrigibly wicked shall have a greater portion of misery than happiness, are truths which cannot be controverted by any one who admits that the Almighty governor of the universe is a Being of wisdom, goodness, and justice. But respecting the rewards of virtue and the punishment of vice, more than these general truths seems not to be taught by natural religion. Many divines, however, of great learning and worth, have thought otherwise, and have contended, that from the nature of things, the rewards bestowed by an infinite God upon piety and virtue must be eternal like their author. These men, indeed, appear willing enough to allow that the punishments with which natural religion is armed against vice must be only of a temporary duration, because reason, say they, is ready to revolt at the thought of *everlasting* punishment.

This opinion, which confounds natural with revealed religion, giving to the former an important truth which belongs exclusively to the latter, has been so ably confuted by Warburton, (Div. Leg. b. ix.) that we shall submit his arguments to our readers in preference to any thing which we ourselves can give.

"If reason doth, on the one hand, seem to revolt at *everlasting punishment*, we must confess that fancy, on the other, (even when full plumed by *vanity*), hath scarcely force enough to rise to the idea of *infinite rewards*. How the heart of man came to consider this as no more than an adequate retribution for his right conduct during the short trial of his virtue here, would be hard to tell, did we not know what monsters PRIDE begot of old upon *pagan philosophy;* and how much greater still these latter ages have disclosed, *by the long* incubation of *school-divinity* upon *folly*. What hath been urged from natural reason, in support of this extravagant presumption, is so very slender, that it recoils as you enforce it. First, you say, 'that the soul, the subject of these eternal rewards, being *immaterial*, and so, therefore, unaffected by the causes which bring material things to an end, is, by its nature, fitted for eternal rewards.' This is an argument *ad ignorantiam*, and holds no farther. Because an *immaterial* being is not subject to that mode of dissolution which affects *material* substances, you conclude it to be eternal. This is going too fast. There may be, and probably are, many natural causes (unknown indeed to us) whereby immaterial beings come to an end. But if the nature of things cannot, yet God certainly can, put a final period to such a being when it hath served the purpose of its creation. Doth ANNIHILATION impeach that wisdom and goodness which was displayed when God brought it *out of nothing?* Other immaterial beings there are, viz., the souls of brutes, which have the same natural security with man for their existence, of whose *eternity* we never dream. But pride, as the poet observes, *calls God unjust*,

> If man alone engross not heaven's high care;
> Alone made *perfect* here, IMMORTAL there.

However, let us (for argument's sake) allow the human soul to be unperishable by nature, and secured in its existence by the unchangeable will of God, and see what will follow from thence.—An *infinite* reward for virtue during one moment of its existence, because reason discovers that, by the law of nature, *some* reward is due? By no means. When God hath amply repaid us for the performance of our duty, will he be at a loss how to dispose of us for the long remainder of *eternity?* May he not find new and endless employment for reasonable creatures, to which, when properly discharged, new rewards, and in endless succession, will be assigned? Modest reason seems to dictate this to the followers of the *law of nature*. The flattering expedient of ETERNAL REWARDS for virtue here was invented in the simplicity of early speculation, after it had fairly brought men to conclude that the soul is immaterial.

"Another argument urged for the eternity of the rewards held out by natural religion, to the practice of piety and virtue, is partly physical and partly moral. The merit of service (say the admirers of that religion) increases in proportion to the excellence of that Being to whom our service is directed and becomes acceptable. An infinite being, therefore, can dispense no rewards but what are infinite. And thus the virtuous man becomes entitled to immortality.

"The misfortune is, that this reasoning holds equally on the side of the unmerciful doctors, as they are called, who doom the wicked to EVERLASTING PUNISHMENT. Indeed, were this the only discredit under which it labours, the merciless doctors would hold themselves little concerned. But the truth is, that the argument from *infinity* proves just nothing. To make it of any force, both the parties should be *infinite*. This inferior emanation of God's *image*, MAN, should either be supremely good or supremely bad, a kind of deity or a kind of devil. But these reasoners, in their attention to the *divinity*, overlook the *humanity*, which makes the decrease keep pace with the accumulation, till the rule of logic, that the *conclusion follows the weaker* part, comes in to end the dispute."

These arguments seem to prove unanswerably, that immortality is not essential to any part of the compound being man, and that it cannot be claimed as a reward due to his virtue. It is not, indeed, essential to any created being, for what has not existence of itself, cannot of itself have perpetuity of existence (see METAPHYSICS); and as neither man nor angel can be profitable to God, they cannot claim from him any thing as a debt. Both, indeed, as moral agents, have duties prescribed to them; and while they faithfully perform those duties, they have all the security which can arise from the perfect benevolence of him who brought them into existence, that they shall enjoy a sufficient portion of happiness to make that existence preferable to non-existence; but reason and philosophy furnish no data from which it can be inferred that they shall exist for ever. Man is partly composed of perishable materials. However perfect Adam may be thought to have been when he came first from the hands of his Creator, his body, as formed of the dust of the ground, must have been naturally liable to decay and dissolution. His soul, indeed, was of a more durable substance; but as it was formed to animate his body, and had no prior conscious existence, it is not easy to conceive what should have led him, under an equal providence, where rewards and punishments were exactly distributed, to suppose that one part of him should survive the other.

SECT. III.—*Condition of Man in Paradise.*

Bishop Warburton has advanced the notion that Adam, after his creation, lived for some time under the dispensation of simple natural religion before he was admitted into Paradise, where he was placed under a new dispensation. (Div. Leg. book ix. chap. 1.) To this opinion we are disposed to assent, though not altogether in the form nor for the reasons which the author has adduced. It appears clear from the sacred narrative that though Adam and his wife were created on the sixth day, they were not *on that day* introduced into Paradise. After telling us that on the sixth day God finished all his works, which he saw to be very good, and rested on the seventh day, Moses briefly recapitulates the history of the generations of the heavens and of the earth, gives us a more particular account of the formation of the first man, informing us that the "Lord God formed him out of the dust of the ground, and breathed into his nostrils the breath of life, when man became a living soul;" and then proceeds to say, (Gen. ii. 7, 8, and 15,) that the "Lord God planted a garden eastward in Eden, where he put the man whom he HAD *formed*." From this short history of the first pair it appears evident beyond dispute, that neither the man nor the woman was formed *in* the garden; and that from their creation some time elapsed before the garden was prepared for their reception, is likewise evident from a comparison of Gen. i. 29, with Gen. ii. 16, 17. In the first of these passages God gives to man, immediately after his creation, "every herb bearing seed which was upon the face of all the earth, and *every tree*, without exception, in which was the fruit of a tree bearing seed: to him he said it should be for meat." In the second, "he commanded the man, saying, of every tree of the garden thou mayest freely eat; but of the tree of knowledge of good and evil, thou shalt not eat of it; for in the day thou eatest thereof thou shalt surely die." When the first grant of food was given, Adam and his wife must have been where no tree of knowledge grew, and they must have been intended to live at least so long in that state as that they should have occasion for food, otherwise the formal grant of it would have been not only superfluous, but apt to mislead them with respect to the subsequent restriction.

In Paradise Adam was placed under a new law, and by the grace of God assured of a supernatural and eternal reward in case of perfect obedience. "And the Lord God," says Moses, "planted a garden eastward in Eden, and took the man and put him in the garden to dress it and to keep it. And the Lord God," continues he, "commanded the man, saying, Of every tree of the garden thou mayest freely eat; but of the tree of the knowledge of good and evil thou shalt not eat of it; for in the day that thou eatest thereof, thou shalt surely die," (Gen. ii. 8, 15, 16, 17.) Here is no mention made of the laws of piety and moral virtue resulting from the relations in which the various individuals of the human race stand to each other, and in which all his creatures stand to God, their Almighty and beneficent Creator. With these laws Adam was already well acquainted; and he must have been sensible, that as they were founded in his nature, no subsequent law could dispense with their obligation. They have been equally binding on all men in every state and under every dispensation; and they will continue to be so as long as the general practice of justice, mercy, and piety, shall contribute to the sum of human happiness. The new law peculiar to his paradisaical state was the command not to eat of the fruit of the tree of the knowledge of good and evil. This was a positive precept, not founded in the nature of man, but very proper to be the test of his obedience to the will of his Creator. The laws of piety and virtue are sanctioned by nature, or by that general system of rules according to which God governs the physical and moral worlds, and by which he has secured, in some state or other, happiness to the pious and virtuous man, and misery to such as shall prove incorrigibly wicked. The law respecting the forbidden fruit was sanctioned by the penalty of *death* denounced against disobedience; and by the subjects of that law the nature of this penalty must have been perfectly understood: but Christian divines, as we shall afterwards see, have differed widely in opinion respecting the full import of the Hebrew words which our translators have rendered by the phrase *thou shalt surely die*. All however agree that they threatened death, in the common acceptation of the word, or the separation of the soul and body, as one part of the punishment to be incurred by eating the forbidden fruit; and hence we must infer, that had the forbidden fruit not been eaten, our first parents would never have died, because the penalty of death was denounced against no other transgression. What, therefore, is said respecting the fruit of the tree of knowledge, implies not only a law but also a covenant,[1] promising to man, upon the observance of one positive precept, immortality or eternal life; which is not essential to the nature of any created being, and cannot be claimed as the merited reward of the greatest virtue or the most fervent piety.

---

[1] It does not appear that any transaction between God and mankind, in general, was denominated by a word equivalent to the English word *covenant* till the end of the fourth century, when such phraseology was introduced into the church by the celebrated Augustin, bishop of Hippo. That the phraseology is strictly proper, no man can suppose who reflects on the infinite distance between the contracting parties, and absolute dominion of the one over the other. To be capable of entering into a *covenant*, in the proper sense of the word, both parties must have a right either to agree to the terms proposed or to reject them; but surely Adam had no right to bargain with his Maker, or to refuse the gift of immortality on the terms on which it was offered to him. The word *dispensation* would more accurately denote what is here meant by the word *covenant*; but as this last is in general use, we have retained it as sufficient, when thus explained, to distinguish what man received from God upon certain positive conditions, from what he had a claim to by the constitution of his nature.

This obvious truth will enable us to dispose of the objections which have been sometimes brought by free-thinking divines against the wisdom and justice of punishing so severely as by death the breach of a mere positive precept; which, considered in itself, appears to be a precept of very little importance. We have only to reply, that as an exemption from death is not due either to the nature or to the virtue of man, it was wise and just to make it depend on the observance of a positive precept, to impress on the minds of our first parents a constant conviction, that they were to be preserved immortal, not in the ordinary course of divine providence, but by the special grace and favour of God. The same consideration will show us the folly of those men who are for turning all that is said of the trees of knowledge and of life into figure and allegory. But the other trees of which Adam and Eve were permitted to eat, were certainly real trees, or they must have perished for want of food. And what rules of interpretation will authorise us to interpret *eating* and *trees* literally in one part of the sentence, and figuratively in the other? A garden in a delightful climate is the very habitation, and the fruits produced in that garden the very food, which we should naturally suppose to have been prepared for the progenitors of the human race; and though in the garden actually fitted up for this purpose two trees were remarkably distinguished from the rest, perhaps in situation and appearance, as well as in use, the distinction was calculated to serve the best of purposes. The one called the *tree of life*, of which, while they continued innocent, they were permitted to eat, served as a sacramental pledge or assurance on the part of God, that as long as they should observe the terms of the covenant their life should be preserved; the other, of which it was death to taste, was admirably adapted to impress on their minds the necessity of implicit obedience to the Divine will, in whatever manner it might be made known to them.

A question of some importance has been started, What would have finally become of men if the first covenant had not been violated? That they would have been all immortal is certain; but it is by no means clear that they would have lived for ever on this earth. On the contrary, it has been an article of very general belief in all ages of the church, (See Bull's State of Man before the Fall,) that the garden of Eden was an emblem or type of heaven, and therefore called *Paradise* (see PARADISE); and that under the first covenant, mankind, after a sufficient probation here, were to be translated into heaven without tasting death. This doctrine is not indeed explicitly taught in Scripture; but many things conspire to make it highly probable. The frequent communications between God and man before the fall,[1] seem to indicate that Adam was training up for some higher state than the terrestrial paradise. Had he been intended for nothing but to cultivate the ground and propagate his species, he might have been left like other animals to the guidance of his own reason and instincts; which, after the rudiments of knowledge were communicated to him, must surely have been sufficient to direct him to everything necessary to the comforts of a life merely sensual and rational, otherwise he would have been but an imperfect animal. It is obvious too, that this earth, however fertile it may have originally been, could not have afforded the means of subsistence to a race of immortal beings multiplying to infinity. For these reasons, and others which will readily occur to the reader, it seems incontrovertible, that under the first covenant, either mankind would have been successively translated to some superior state, or would have ceased to propagate their kind as soon as the earth should have been replenished with inhabitants. He who reflects on the promise, that, after the general resurrection, there is to be a new heaven and a new earth, will probably embrace the latter part of the alternative; but that part in its consequences differs not from the former. In the new earth promised in the Christian revelation, nothing is to dwell but righteousness. It will therefore be precisely the same with what we conceive to be expressed by the word heaven; and if under the first covenant this earth was to be converted into a similar place, where, after a certain period, men should never marry nor be given in marriage, but enjoy what divines have called the *beatific vision*, we may confidently affirm, that, had the first covenant been faithfully observed, Adam and his posterity, after a sufficient probation, would all have been translated to some superior state or heaven.

To fit them for that state, the gifts of divine grace seem to have been absolutely necessary. To them it was a state certainly supernatural, otherwise a God of infinite wisdom and perfect goodness would not, for a moment, have placed them in an inferior state. But to enable any creature, especially such a creature as man, whom an ancient philosopher has justly styled *ζωον μιμητικον*, to rise above its *nature*, foreign and divine aid is unquestionably requisite; and therefore, though we cannot persuade ourselves that the gifts of the Holy Ghost constituted that image of God in which man was originally made, we agree with Bishop Bull, that these gifts were bestowed on our first parents to enable them to fulfil the terms of the covenant under which they were placed.

On the whole, we think it apparent from the portions of scripture which we have examined, that Adam and Eve were endued with such powers of body and mind as fitted them to exercise dominion over the other animals; that those powers constituted that image of God in which they are said to have been formed; that they received by immediate revelation the first principles of all useful knowledge, and especially of that system which is usually called *natural religion*; that they lived for some time with no other religion, entitled to the natural rewards of piety and virtue, but all the while liable to death; that they were afterwards translated into Paradise, where they were placed under a new law, with the penalty of death threatened to the breach of it, and the promise of endless life if they should faithfully observe it; and that they were endued with the gifts of the Holy Ghost, to enable them, if not wanting to themselves, to fulfil the terms of that covenant, which has been improperly termed the *covenant of works*, since it flowed from the mere grace of God, and conferred privileges on man to which the most perfect human virtue could lay no just claim.

SECT. IV.—*Of the Fall of Man.*

From the preceding account of the primeval state of man, it is evident that his continuance in the terrestrial paradise, together with all the privileges which he there enjoyed, were made to depend on his observance of one positive precept. Every other duty incumbent on him, whether as resulting from what is called the law of his nature, or from the express command of his God, was as much his duty before as after he was introduced into the garden of Eden; and though the transgression of any law would undoubtedly have been punished, it does not appear that a breach of the *moral* law, or of the commandment respecting the sanctification of the *Sabbath-day*, would have been punished with death, whatever may be the import of that word in the place where it is first threatened. The punishment was denounced only against eating the fruit of the tree of the knowledge of good and evil: For "the Lord commanded the man saying, Of every tree of the garden thou mayest freely eat, but of the tree of the knowledge of good and evil thou shalt not eat of it; for in the day that thou eatest thereof thou shalt surely die." To the word *death* in this passage divines have affixed many and different meanings. By some it is supposed to import a separation of the soul and body, while the latter was to continue in a state of conscious existence; by others, it is taken to imply annihilation, or a state without consciousness; by some, it is imagined to signify eternal life in torments; and by others a spiritual and moral death, or a state necessarily subject to sin. In any one of these acceptations it denoted something new to Adam, which he could not understand without an explanation of the term; and therefore, as it was threatened as the punishment of only one transgression, it could not be the divine intention to inflict it on any other.

---

[1] That there were such frequent communications, has been shown to be in the highest degree probable, by the late Dr. Law, bishop of Carlisle. See his Discourses on the several Dispensations of Revealed Religion.

The abstaining from a particular fruit in the midst of a garden abounding with fruits of all kinds, was a precept which at first view appears of easy observation; and the penalty threatened against the breach of it was, in every sense, awful. The precept, however, was broken notwithstanding that penalty; and though we may thence infer that our first parents were not beings of such absolute perfection as by divines they have sometimes been represented, we shall yet find, upon due consideration, that the temptation by which they were seduced, when taken with all its circumstances, was such as no wise and modest man will think himself able to have resisted. The short history of this important transaction we have in the third chapter of the book of Genesis, ver. 1–6.

To our readers, on referring to this passage, the conversation between the serpent and the woman must appear to begin abruptly; and indeed it is not possible to reconcile it with the natural order of a dialogue, or even with the common rules of grammar, but by supposing the tempter's question, "Yea, hath God said, ye shall not eat of every tree of the garden?" to have been suggested by something immediately preceding either in words or in significant signs. Eve had undoubtedly by some means or other informed the serpent that she was forbidden to eat of the fruit on which he was probably feasting; and that information, whether given in words or in actions, must have produced the question with which the sacred historian begins his relation of this fatal dialogue. We are told that the woman *saw* that the tree was *good for food;* that it was pleasant to the eyes, and a tree to *be desired to make one wise;* but all this she could not have *seen*, had not the serpent eaten of its fruit in her presence. In her walks through the garden, it might have often appeared pleasant to her eyes; but previously to experience she could not know but that its fruit was the most deadly poison, far less could she conceive it capable of conferring wisdom. But if the serpent ate of it before her, and then extolled its virtues in rapturous and intelligible language, she would at once see that it was not destructive of animal life, and naturally infer that it had very singular qualities. At the moment she was drawing this inference, it is probable that he invited her to partake of the delicious fruit, and that her refusal produced the conference before us. That she yielded to his temptation, need excite no wonder; for she knew that the serpent was by nature a brute animal, and if he attributed his speech to the virtues of a tree, she might infer, with some plausibility, that what had power to raise the brute mind to human, might raise the human to divine, and make her and her husband, according to the promise of the tempter, become as gods, knowing good and evil.

Full of these hopes of raising herself to divinity, and not, as has sometimes been supposed, led headlong by a sensual appetite, she took of the fruit and did eat, and gave to her husband with her, and he did eat.

SECT. V.—*Immediate Consequences of Adam's Transgression and Fall.*

The covenant, which, on the introduction of our first parents into Paradise, their Creator was graciously pleased to make with them, having been broken by their violation of the condition on which they were advanced to that supernatural state, the historian tells us, that "lest they should put forth their hand and take also of the tree of life and eat, and live for ever, the Lord God sent them forth from the garden of Eden, to till the ground from whence they were taken." Had they been so sent forth without any farther intimation respecting their present condition or their future prospects, and if the death under which they had fallen was only a loss of consciousness, they would have been in precisely the same state in which they lived before they were placed in the garden of Eden; only their minds must now have been burdened with the inward sense of guilt, and they must have *known* themselves to be subject to death; of which, though not exempted from it by nature, they had probably no *apprehension* till it was revealed to them in the covenant of life which they had so wantonly broken.

God did not however send them forth thus hopeless and forlorn from the Paradise of delights which they had so recently forfeited. He determined to punish them for their transgression, and at the same time to give them an opportunity of recovering more than their lost inheritance. Calling therefore the various offenders before him, and inquiring into their different degrees of guilt, he began with pronouncing judgment on the serpent in terms which implied that there was mercy for man. "And the Lord God said unto the serpent, Because thou hast done this, thou art cursed above all cattle, and above every beast of the field: upon thy belly shalt thou go, and dust shalt thou eat all the days of thy life; and I will put enmity between thee and the woman, and between thy seed and her seed: it shall bruise thy head, and thou shalt bruise his heel."

That this sentence has been fully inflicted on the serpent, no reasoning can be necessary to evince. Every species of that reptile is more hateful to man than any other terrestrial creature; and there is literally a perpetual war between them and the human race. It is remarkable too, that the *head* of this animal is the only part which it is safe to bruise. His tail may be bruised, or even cut off, and he will turn with fury and death on his adversary; but the slightest stroke on the head infallibly kills him. That the serpent, or at least the greater part of serpents, go on their belly, every one knows; though it is said, that in some parts of the east, serpents have been seen with wings, and others with feet, and that these species are highly beautiful. If there be any truth in this story, we may suppose that these walking and flying serpents have been suffered to retain their original elegance, that mankind might see what the whole race was before the curse was denounced on the tempter of Eve; but it is certain that most of the species have neither wings nor feet, and that many of the most poisonous of them live in burning deserts, where they have nothing to eat but the dust among which they crawl.

Obs. 1. See Bochart, *Hierozoicon*, lib. i. cap. 4. Bruce's Travels.

Obs. 2. To this degradation of the serpent, infidels have objected, that it implies the punishment of an animal which was incapable of guilt; but this objection is founded in thoughtlessness and ignorance. The elegant form of any species of inferior animals adds nothing to the happiness of the animals themselves; the ass is probably as happy as the horse, and the serpent that crawls as he that flies. Fine proportions attract indeed the notice of man, and tend to impress upon his mind just notions of the wisdom and goodness of the Creator; but surely the symmetry of the horse, or the beauty of the peacock, is more properly displayed for this purpose, than the elegance of the instrument employed by the enemy of mankind. The degradation of the serpent in the presence of our first parents must have served the best of purposes. If they had so little reflection as not yet to have discovered that he was only the instrument with which a more powerful being had wrought their ruin, they would be convinced, by the execution of this sentence, that the forbidden fruit had no power in itself to improve the nature either of man or of beast. But it is impossible that they could be so stupid as this objection supposes them. They doubtless knew by this time that some great and wicked spirit had actuated the organs of the serpent; and that when enmity was promised to be put between its seed and the seed of the woman, that promise was not meant to be fulfilled by serpents occasionally biting the heels of men, and by men in return bruising the heads of serpents. If such enmity, though it has literally taken place, was all that was meant by this prediction, why was not Adam directed to bruise the head of the identical serpent which had deluded his wife? If he could derive any consolation from the exercise of revenge, surely it would be greater from his revenging himself on his own enemy, than from the knowledge that there should be a perpetual warfare between his descendants and the breed of serpents through all generations.

We cannot doubt but that their gracious and merciful Creator would inform our first parents, that they had a powerful enemy; that he was a rebellious angel capable of deceiving them in many ways; and that they ought therefore to be constantly on their guard against his wiles. They must have known that they were themselves animated by something different from matter; and when they found they were deceived by the serpent, they might surely, without any remarkable stretch of sagacity, infer that their malignant enemy had actuated the organs of that creature in a manner somewhat similar to that in which their own souls actuated their own bodies. If this be admitted, the degradation of the serpent would convince them of the weakness of the tempter when compared with their Creator; and confirm their hopes, that since he was not able to preserve unhurt his own instrument of mischief, he should not be able finally to prevail against them; but that though he had bruised their heels, the promised seed of the woman should at last bruise his head, and recover the inheritance which they had lost. See PROPHECY.

Having thus punished the original instigator to evil, the Almighty Judge turned to the fallen pair, and said to the woman, "I will greatly multiply thy sorrow and thy conception: in sorrow thou shalt bring forth children; and thy desire shall be to thy husband, and he shall rule over thee. And unto Adam he said, Because thou hast hearkened unto the voice of thy wife, and hast eaten of the tree, of which I commanded thee, saying, Thou shalt not eat of it: cursed is the ground for thy sake; in sorrow shalt thou eat of it all the days of thy life: Thorns also and thistles shall it bring forth unto thee, and thou shalt eat the herb of the field. In the sweat of thy face shalt thou eat bread, till thou return unto the ground; for out of it wast thou taken: for dust thou art, and unto dust shalt thou return."

Here is a terrible denunciation of toil and misery and death upon two creatures; who, being inured to nothing, and formed for nothing but happiness, must have felt infinitely more horror from such a sentence, than we, who are familiar with death, intimate with misery, and "born o sorrow as the sparks fly upward," can form any adequate conception of. The hardship of it seems to be aggravated by its being severer than what was originally threatened against the breach of the covenant of life. It was indeed said, "In the day thou eatest thereof, thou shalt surely die;" but no mention was made of the woman's incurring sorrow in conception, and in the bringing forth of children; of the curse to be inflicted on the ground; of its bringing forth thorns and thistles instead of food for the use of man; and of Adam's eating bread in sorrow and the sweat f his face till he should return to the dust from which he was taken.

These seeming aggravations, however, are in reality intances of divine benevolence. Adam and Eve were now ubjected to death; but in the sentence passed on the serent, an obscure intimation had been given them that they were not to remain for ever under its power. It was therefore their interest, as well as their duty, to reconcile themselves as much as possible to their fate; to wean their affections from this world, in which they were to live only for a time; and to hope, with humble confidence, in the promise of their God, that, upon their departure from it, they should be received into some better state. To enable them to wean their affections from earth, nothing could more contribute than to combine sensual enjoyment with sorrow, and lay them under the necessity of procuring their means of subsistence by labour, hard and often fruitless. This would daily and hourly impress upon their minds a full conviction that the present world is not a place fit to be an everlasting habitation; and they would look forward, with pious resignation, to death, as putting a period to all their woes. Had they indeed been furnished with no ground of hope beyond the grave, we cannot believe that the righteous Judge of all the earth would have added to the penalty originally threatened. That penalty they would doubtless have incurred the very day on which they fell; but as they were promised a deliverance from the consequences of their fall, it was proper to train them up by severe discipline for the happiness reserved for them in a future state.

After the passing of their sentence, the man and woman were turned out into the world, where they had formerly lived before they were placed in the garden of Eden; and all future access to the garden was for ever denied them. They were not, however, in the same state in which they originally were before their introduction into Paradise. They were now conscious of guilt, doomed to severe labour, liable to sorrow and sickness, disease and death.

SECT. VI.—*Remoter Consequences of the Fall.*

As all mankind are descended from Adam and Eve, all have become exposed to certain penal consequences of their transgression. It may seem indeed to detract from the moral attributes of God, to inflict misery on children for the sins of their parents; but before any thing can be pronounced concerning the Divine goodness and justice in the present case, we must know precisely how much we suffer in consequence of Adam's transgression, and whether we have ourselves any share in that guilt which is the cause of our sufferings.

That women would have had less sorrow in the bringing forth of children; that we should have been subjected to less toil, and exempted from death, had our first parents not fallen from their paradisaical state, are truths incontrovertible by him who believes the inspiration of the holy Scriptures; but that mankind would in that state have been wholly free from pain and every bodily distress, is a proposition which is not to be found in the Bible, and which therefore no man is bound to believe. The bodies of Adam and Eve consisted of flesh, blood, and bones, as ours do; they were surrounded by material objects as we are; and their limbs were unquestionably capable of being fractured. That their souls should never be separated from their bodies while they abstained from the forbidden fruit, they knew from the infallible promise of him who formed them, and breathed into their nostrils the breath of life; but that not a bone of themselves or of their numerous posterity should ever be broken by the fall of a stone or of a tree, they were not told, and had no reason to expect. Of such fractures, pain would surely have been the consequence; though we have reason to believe that it would have been quickly removed by some infallible remedy, probably by the fruit of the tree of life.

Perhaps it may be said, that if we suppose our first parents or their children to have been liable to accidents of this kind in the garden of Eden, it will be difficult to conceive how they could have been preserved from death, as a stone might have fallen on their heads as well as on their feet, and have at once destroyed the principle of vitality. But this can be said only by him who knows little of the physical world, and still less of the power of God. There are many animals which are susceptible of pain, and yet not easily killed; and man in Paradise might have resembled these. At any rate, we are sure that the omnipotent Creator could and would have preserved him from death; but we have no reason to believe that, by a constant miracle, he would have preserved him from every kind of pain. Indeed, if, under the first covenant, mankind were in a state of probation, it is certainly conceivable that some one individual of the numerous race might have fallen into sin, without actually breaking the covenant by eating the fruit of the tree of knowledge; and such a sinner would undoubtedly have been punished by that God who is of purer eyes than to behold iniquity; but how punishment could have been inflicted on a being exempted from all possibility of pain as well as of death, we confess ourselves unable to imagine. Remorse, which is the inseparable consequence of guilt, and constitutes in our present state great part of its punishment, flows from the fearful looking for of judgment, which the sinner knows shall, in a future state, devour the adversaries of the gospel of Christ; but he, who could neither suffer pain nor death, had no cause to be afraid of future judgment, and was therefore not liable to the tortures of remorse. We conclude, therefore, that it is a mistake to suppose pain to have been introduced into the world by the fall of our first parents, or at least that the opinion contrary to ours has no foundation in the word of God.

Death, however, was certainly introduced by their fall; for the inspired apostle assures us, that in *Adam all die*, (Cor. xv. 22); and again, that *through the offence of* ONE *many are dead*, (Rom. v. 15.) But concerning the full import of the word *death* in this place, and in the sentence pronounced upon our first parents, divines hold opinions extremely different. Many contend, that it includes death *corporal*, *spiritual* or *moral*, and *eternal*; and that all mankind are subjected to these three kinds of death, on account of their share in the guilt of the original transgression, which is usually denominated *original sin*, and considered as the source of moral evil.

That all men are subjected to death corporal in consequence of Adam's transgression, is universally admitted; but that they are in any sense partakers of his guilt, and on that account subjected to death spiritual and eternal, has been very strenuously denied. To discover the truth is of great importance; for it is intimately connected with the Christian doctrine of redemption. We shall therefore state, with as much impartiality as we can, the arguments commonly urged on each side of this much agitated question.

Those who maintain that all men sinned in Adam, generally state their doctrine thus: " The covenant being made with Adam as a public person, not for himself only, but for his posterity, all mankind descending from him by ordinary generation, *sinned* in him, and fell with him in that first transgression; whereby they are deprived of that original righteousness in which he was created, and are utterly indisposed, disabled, and made opposite to all that is spiritually good, and wholly inclined to all evil, and that continually; which is commonly called *original sin*, and from which do proceed all actual transgressions, so as we are by nature children of wrath, bond-slaves to Satan, and justly liable to all punishments in this world and in that which is to come, even to everlasting separation from the comfortable presence of God, and to most grievous torments in soul and body, without intermission, in hell-fire for ever."

What in this passage we are first to examine, is the sentence which affirms all mankind descending from Adam by ordinary generation, to have *sinned* in him and fallen with him in his first transgression; the truth of which is attempted to be proved by various texts of holy Scripture. Thus, St. Paul says expressly, that " by one man sin entered into the world, and death by sin; and so death passed upon all men, for that *all have sinned*. But not as the offence, so also is the free gift. For if, through the *offence* of *one many* be *dead*, much more the grace of God, and the gift of grace, which is by one man, Jesus Christ, hath abounded unto many; and not as it was by one that sinned, so is the gift (for the *judgment* was by *one* unto *condemnation*); but the free gift is of many offences unto justification. For if, by one man's offence, death reigned by one; much more they, who receive the abundance of grace and of the gift of righteousness, shall reign in life by one, Jesus Christ. Therefore as by the *offence of one, judgment* came upon *all men* to *condemnation;* even so, by the righteousness of one, the free gift came upon all men to justification of life. For as by one man's disobedience *many were made sinners;* so by the obedience of one shall many be made righteous." (Rom. v. 12, 15–20.) In this passage the apostle assures us, that all upon whom death has passed have *sinned;* but death has passed upon infants, who could not commit actual sin. Infants therefore must have sinned in Adam, since death has passed upon them; for death "is the wages only of sin." He tells us likewise, that by the offence of one, judgment came upon all men to condemnation; and therefore since the righteous Judge of heaven and earth never condemns the innocent with the wicked, we must conclude, that all men partake of the guilt of that offence for which judgment came upon them to condemnation. These conclusions are confirmed by his saying expressly, that " by one man's disobedience many (*i. e.* all mankind) were *made sinners;*" and elsewhere (Rom. ii. 10. and Eph. ii. 1, 3), that " there is none righteous, no *not one;*" and that his Ephesian converts " were dead in trespasses and sins, and were by *nature* children of wrath even as *others*." The same doctrine, it is said, we are taught by the inspired writers of the Old Testament. Thus Job, expostulating with God for bringing into judgment with him such a creature as man, says, " Who can bring a clean thing out of an unclean? Not one." And Eliphaz, reproving the patient patriarch for what he deemed presumption, asks, (Job xiv. 4. and xv. 14), " What is man that he should be clean, or he who is born of a woman that he should be righteous?" From these two passages it is plain, that Job and his unfeeling friend, though they agreed in little else, admitted as a truth unquestionable, that man inherits from his parents a sinful nature, and that it is impossible for any thing born of a woman by ordinary generation to be righteous. The Psalmist speaks the very same language, when aknowledging his transgressions, he says, (Psalm ii. 5), " Behold I was shapen in iniquity, and in sin did my mother conceive me."

Having thus proved the fact, that all men are made sinners by Adam's disobedience, the divines who embrace this side of the question, proceed to inquire how they can be partakers in guilt which was incurred so many ages before they were born. It cannot be by imitation; for infants, according to them, are involved in this guilt before they be capable of imitating any thing. Neither do they admit that sin is by the apostle put for the consequences of sin, and many said to be made sinners by one man's disobedience, because by that disobedience they were subjected to death, which is the wages of sin. This, which they call the doctrine of the Arminians, they affirm to be contrary to the whole scope and design of the context; as it confounds together sin and death, which are there represented, the one as the cause, and the other as the effect. It likewise exhibits the apostle reasoning in such a manner as would, in their opinion, disgrace any man of common sense, and much more an inspired writer; for then the sense of these words, " Death hath passed upon all men, for that all have sinned," must be, death has passed upon all men, because it hath passed upon all men; or, all men are obnoxious to death, because they are obnoxious to death. The only way, therefore, continue they, in which Adam's posterity can be made sinners through his disobedience, is by the IMPUTATION of his disobedience to them; and this imputation is not to be considered in a *moral* sense, as the action of a man committed by himself, whether good or bad, is reckoned to him as his own; but in a *forensic* sense, as when one man's debts are in a legal way placed to the account of another. Of this we have an instance in the apostle Paul, who said to Philemon concerning Onesimus, "If he hath wronged thee, or oweth thee any thing, (ἐλλογει) impute it to me," or place it to my account. And thus the posterity of Adam are made sinners by his disobedience; that being imputed to them and placed to their account, as if it had been committed by them personally, though it was not.

Some few divines of this school are indeed of opinion, that the phrase, "By one man's disobedience many were made sinners," means nothing more than that the posterity of Adam, through his sin, derive from him a corrupt nature. But though this be admitted as an undoubted truth, the more zealous abettors of the system contend, that it is not the whole truth. "It is true," say they, "that all men are made of one man's blood, and that blood tainted with sin; and so a clean thing cannot be brought out of an unclean. What is born of the flesh is flesh, carnal and corrupt: every man is conceived in sin, and shapen in iniquity; but there is a difference between being *made sinners*, and *becoming* sinful. The one respects the *guilt*, the other the *pollution* of nature; the one is previous to the other, and the foundation of it. Men receive a corrupt nature from their immediate parents; but they are made sinners, not by any act of their disobedience, but only by the imputation of the sin of Adam."

To illustrate this doctrine of imputed sin, they observe, that the word κατεσταθησαν, used by the apostle, signifies *constituted* in a judicial way, ordered and appointed in the dispensation of things that so it should be; just as Christ was made sin or a sinner by imputation, or by that constitution of God which laid upon him the sins of all his people, and dealt with him as if he had been the guilty person. That this is the sense of the passage, they argue further from the punishment inflicted on men for the sin of Adam. The punishment threatened to that sin was death; which includes death corporal, moral, and eternal. Corporal death, say they, is admitted by all to be suffered on account of the sin of Adam; and if so, there must be guilt, and that guilt made over to the sufferer, which can be done only by *imputation*. A moral death is no other than the loss of the image of God in man, which consisted in righteousness and holiness; and particularly it is the loss of original righteousness, to which succeeded unrighteousness and unholiness. It is both a sin and a punishment for sin; and since it comes on all men as a punishment, it must suppose preceding sin, which can be nothing but Adam's disobedience, the guilt of which is made over to his posterity by *imputation*. This appears still more evident from the posterity of Adam being made liable to eternal death in consequence of his transgression; for the wages of sin is death, even death eternal, which never can be inflicted on guiltless persons. But from the passage before us we learn, that "by the offence of *one* judgment came upon all men to condemnation;" and therefore the guilt of that offence must be reckoned to all men, or they could not be justly condemned for it. That Adam's sin is imputed to his posterity, appears not only from the words, "by one man's disobedience many were made sinners;" but likewise from the opposite clause, "so by the obedience of one shall many be made righteous;" for the many ordained to eternal life, for whom Christ died, are made righteous, or justified, only through the imputation of his righteousness to them; and therefore it follows, that all men are made sinners only through the imputation of Adam's disobedience.

To this doctrine it is said to be no objection that Adam's posterity were not in being when his sin was committed; for though they had not then actual being, they had yet a virtual and representative one. They were in him both *seminally* and *federally*, and sinned in him, (Rom. v. 12); just as Levi was in the loins of Abraham, and paid in him tithes to Melchizedec, (Heb. vii. 9, 10.) From Adam they derive a corrupt nature; but it is only from him, as their federal head, that they derive a share of his guilt, and are subjected to his punishment. That he was a federal head to all his posterity, the divines of this school think evident from his being called a figure of Christ, (Rom. v. 14); and the first Adam described as natural and earthly, in contradistinction to Christ the second Adam, described as spiritual and the Lord from heaven; and from the punishment threatened against his sin being inflicted not on himself only, but on all his succeeding offspring. He could not be a figure of Christ, say they, merely as a man; for all the sons of Adam have been men as well as he, and in that sense were as much figures of Christ as he; yet Adam and Christ are constantly contrasted, as though they had been the only two men that ever existed, because they were the only two heads of their respective offspring. He could not be a figure of Christ on account of his extraordinary production; for though both were produced in ways uncommon, yet each was brought into the world in a way peculiar to himself. The first Adam was formed of the dust of the ground; the second, though not begotten by a man, was born of a woman. They did not therefore resemble each other in the manner of their formation, but in their office as covenant-heads; and in that alone the comparison between them is exact.

Nor have any of the posterity of Adam, it is said, reason to complain of such a procedure. Had he stood in his integrity, they would have been, by his standing, partakers of all his happiness; and therefore should not murmur at receiving evil through his fall. If this do not satisfy, let it be considered, that since God, in his infinite wisdom, thought proper that men should have a head and representative, in whose hands their good and happiness should be placed, none could be so fit for this high station as the common parent, made after the image of God, so wise, so holy, just, and good. Lastly, to silence all objections, let it be remembered, that what God gave to Adam as a federal head, relating to himself and his posterity, he gave as the Sovereign of the universe, of whom no created being has a right to ask, "What dost thou?" (See Gill's Body of Divinity.)

Such are the consequences of Adam's fall, and such the doctrine of original sin, as maintained by the more rigid followers of Calvin. That great reformer, however, was not the author of this doctrine. It had been taught so early as in the beginning of the fifth century, by St. Augustin, the celebrated bishop of Hippo; and the authority of that father had made it more or less prevalent in both the Greek and Roman churches long before the Reformation. Calvin was indeed the most eminent modern divine by whom it has been held in all its rigour; and it constitutes one great part of that theological system, which, from being taught by him, is now known by the name of *Calvinism*.

But if it was as Sovereign of the universe that God gave to Adam what he received in Paradise relating to himself and his posterity, Adam could in no sense of the words be a federal head; because, upon this supposition, there was no covenant. The Sovereign of the universe may unquestionably dispense his benefits, or withhold them, as seems expedient to his infinite wisdom; and none of his subjects or creatures can have a right to say to him, "What dost thou?" But the dispensing or withholding of benefits is a transaction very different from the entering into covenants; and a judgment of it is to be formed on very different principles. Every thing around us proclaims that the Sovereign of the universe is a being of perfect benevolence; but, say the disciples of the school now under consideration, the dispensation given to Adam in Paradise was so far from being the offspring of benevolence, that, as it is understood by the followers of Calvin, it cannot possibly be reconciled with the eternal laws of equity. The self-existent and all-sufficient God might or might not have created such a being as man; and in either case there would have been no reason for the question "What dost thou?" But as soon as he determined to create him capable of happiness or misery, he would not have been either benevolent or just, if he had not placed him in a state where, by his own exertions, he might, if he chose, have a greater share of happiness than of misery, and find his existence, upon the whole, a blessing. They readily acknowledge, that the existence of any created being may be of longer or shorter duration, according to the good pleasure of the Creator; and therefore they have no objection to the apostolic doctrine, that "in Adam all die;" for immortality being not a debt, but a *free gift*, may be bestowed on any terms, and with perfect justice withdrawn when those terms are not complied with. Between death, however, as it implies a loss of consciousness, and the extreme misery of eternal life in torments, there is an immense difference. To death all mankind might justly be subjected through the offence of one; because they had originally no claim to be exempted from it, though that one and they too had remained for ever innocent; but eternal life in torments is a punishment which a God of justice and benevolence can never inflict but upon personal guilt of the deepest die. That we can personally have incurred guilt from a crime committed some thousands of years before we were born, is impossible. It is indeed a notion as contrary to reason as to common sense; for the apostle expressly informs us, (1 John iii. 4), "that sin is the transgression of some law;" and the sin of Adam was the transgresion of a law which it was never in our power either to observe or to break. Another apostle (Rom. iv. 15) assures us, that "where no law is, there is no transgression;" but there is now no law, nor has been any these five thousand years, forbidding mankind to eat of a particular fruit; for, according to the Calvinists themselves, (Gill's Body of Divinity, book iii. ch. 10.) Adam had no sooner committed his first sin, by which the covenant with him was broken, than he ceased to be a covenant-head. This law given him was no more; the promise of life by it ceased; and its sanction, death, took place. But if this be so, how is it possible that his unborn posterity should be under a law which had no existence, or that they should be in a worse state in consequence of the covenant being broken, and its promise having ceased, than he himself was before the covenant was first made? He was originally a mortal being, and was promised the supernatural gift of immortality on the single condition of his abstaining from the fruit of the tree of knowledge of good and evil. From that fruit he did not abstain; but by eating it fell back into his natural state of mortality. Thus far it is admitted that his posterity fell with him; for they have no claim to a supernatural gift which he had forfeited by his transgression. But we cannot admit, say the divines of this school, that they fell into his guilt; for to render it possible for a man to incur guilt by the transgression of a law, it is necessary not only that he have it in his power to keep the law, but also that he be capable of transgressing it by a *voluntary* act. But surely no man could be capable of voluntarily eating the forbidden fruit five thousand years before he himself or his volitions existed. The followers of Calvin think it a sufficient objection to the doctrine of transubstantiation, that the same numerical body cannot be in different places at the same instant of time. But this ubiquity of body, say the Remonstrants, is not more palpably absurd, than the supposition that a man could exert volitions before he or his will had any existence.

Nor will the introduction of the word *imputation* into this important question remove a single difficulty. For what is it that we mean by saying that the sin of Adam is imputed to his posterity? Is the guilt of that sin transferred from him to them? So surely thought Dr. Gill, when he said that it *is made over to them.* But this is the same absurdity as the making over of the sensible qualities of bread and wine to the internal substance of the Saviour's body and blood. This imputation either found the posterity of Adam guilty of his sin, or it made them so. It could not find them guilty for the reason already assigned, as well as because the apostle says expressly, that for the offence of *one* judgment came upon *all* men, which would not be true had *all* offended. It could not make them guilty; for this reason, that if there be in physics or metaphysics a single truth self-evident, it is, that the numerical powers, actions, or qualities of one being cannot possibly be transferred to another, and be made its powers, actions, or qualities. Different beings may in distant ages have qualities of the same kind; but as easily may 4 and 3 be made equal to 9, as two beings be made to have the same identical quality. In Scripture we nowhere read of the actions of one man being imputed to another. "Abraham," we are told, "believed in God, and it was counted to him for righteousness;" but it was his *own* faith, and not the faith of another man, that was so counted. "To him that worketh not, but believeth, his faith (not another's) is imputed for righteousness." And of our faith in him that raised Christ from the dead, it is said, that "it shall be imputed, not to our fathers or our children, but to us for righteousness."

When this phrase is used with a negative, not only is the man's own personal sin spoken of, but the non-imputation of that sin means nothing more but that it brings not upon the sinner condign punishment. Thus when Shemei "said unto David, Let not my lord *impute* iniquity unto me;" it could not be his meaning that the king should not think that he had offended; for with the same breath he added, "Neither do thou remember that which thy servant *did perversely*, the day that my lord the king went out of Jerusalem, that the king should take it to his *heart*. For thy servant doth *know* that *I have sinned*." Here he plainly confesses his sin, and declares, that by entreating the king not to *impute it to him*, he wishes only that it should not be so remembered as that the king should take it to heart, and punish him as his perverseness deserved. When therefore it is said, (2 Cor. v. 19,) that "God was in Christ reconciling the world to himself, not imputing to them their iniquities," the meaning is only, that for Christ's sake, he was pleased to exempt them from the punishment due to their sins. In like manner, when the prophet, foretelling the sufferings of the Messiah, says, that "the Lord laid on him the iniquity of us all," his meaning cannot be, that the Lord by *imputation* made his immaculate Son guilty of all the sins that men have ever committed; for in that case it would not be true that the "just suffered for the unjust," as the apostle expressly teaches, (1 Peter iii. 28); but the sense of the verse must be, as Bishop Coverdale translated it, "through him the Lord pardoneth all our sins." This interpretation is countenanced by the ancient version of the Seventy, *και Κυριος παρεδωκεν ἀυτον ταις ἁμαρτιαις ἡμων*: words which express a notion very different from that of imputed guilt. The Messiah was, without a breach of justice, delivered for sins of which he had voluntarily offered to pay the penalty; and St. Paul might have been justly charged by Philemon with the debts of Onesimus, which he desired might be placed to his account. Had the apostle, however, expressed no such desire, surely Philemon could by no deed of his have made him liable for debts contracted by another; far less could he by *imputation*, whatever that word may mean, have made him virtually concur in the contracting of those debts. He could not have been justly subjected to suffering without his own consent; and he could not possibly have been made guilty of the sins of those for whom he suffered.

The doctrine of imputed guilt, therefore, as understood by the Calvinists, is, in the opinion of their opponents, without foundation in Scripture, and contrary to the nature of things. It is an impious absurdity, say they, to which the mind can never be reconciled by the hypothesis, that all men were in Adam both seminally and federally, and sinned in him, as Levi paid tithes to Melchizedec in the loins of Abraham. The apostle, when he employs that argument to lessen in the minds of his countrymen the pride of birth and the lofty opinions of their priesthood, plainly intimates, that he was using a bold figure, and that Levi's paying tithes is not to be understood in a strict and literal sense. "Now consider," says he, "how great this man was, unto whom even the patriarch Abraham gave the tenth of the spoils. And, *I may so say*, Levi also, who receiveth tithes, paid tithes in Abraham: for he was yet in the loins of his father when Melchizedec met him." This is a very good argument to prove that the Levitical priesthood was inferior in dignity to that of Melchizedec; and by the apostle it is employed for no other purpose. Levi could not be greater than Abraham, and yet Abraham was inferior to Melchizedec. This is the whole of St. Paul's reasoning, which lends no support to the doctrine of original sin, unless it can be shown that Levi and all his descendants contracted from this circumstance such a strong propensity to the *paying* of tithes, as made it a matter of extreme difficulty for them, in every subseqent generation, to comply with that part of the divine law which constituted them *receivers* of tithes. That all men were seminally in Adam, is granted; and it is likewise granted that they may have derived from him, by ordinary generation, diseased and enfeebled bodies: but it is as impossible to believe that moral guilt can be transmitted from father to son by the physical act of generation, as to conceive a scarlet colour to be a cube of marble, or the sound of a trumpet a cannon ball. That Adam was as fit a person as any other to be entrusted with the good and happiness of his posterity, may be true; but there is no fitness whatever, according to the Arminians, in making the everlasting happiness or misery of a whole race depend upon the conduct of any fallible individual. "That any man should so represent me," says Dr. Taylor, (Doctrine of Original Sin, part iii.) "that when he is guilty, I am to be reputed guilty; when he trangresses, I am to be accountable and punishable for his transgression; and this before I was born, and consequently before I am in any capacity of knowing, helping, or hindering, what he doth; all this every one who useth his understanding must clearly see to be false, unreasonable, and altogether inconsistent with the truth and goodness of God." And that no such appointment ever had place, he endeavours to prove, by showing that the texts of Scripture upon which is built the doctrine of Calvinists respecting original sin, will each admit of a very different interpretation.

One of the strongest of these texts is Romans v. 19, which we have already quoted, and which our author thus explains. He observes, that the apostle was a Jew, familiarly acquainted with the Hebrew tongue; that he wrote his epistle as well for the use of his own countrymen residing in Rome, as for the benefit of the Gentile converts; and that though he made use of the Greek language, as most generally understood, he frequently employed idioms. Now it is certain that the Hebrew words חטאה and עון, "sin and iniquity," are frequently used in the Old Testament to signify *suffering*, by a figure of speech which puts the effect for the cause; and it is surely more probable, that in the verse under consideration, the apostle used the corresponding Greek word ἁμαρτωλοι in the Hebrew sense, than that he meant to contradict what he had said in the former verse, by teaching that all men were made guilty of an act of disobedience committed thousands of years before the majority of them had any being. In the preceding verse he says, "that by the offence of one, judgment came upon all men to condemnation." But this cannot be true, if by that offence all men were made sinners; for then judgment must have come upon each for his own share in the original disobedience. "Any one may see," says Dr. Taylor, "that there is a vast difference between a man's making *himself* a sinner by his *own* wicked act, and his being made a sinner by the wicked act of *another*. In the latter case, he can be a sinner in no other sense but as he is a sufferer; just as Lot would have been made a sinner with the Sodomites, had he been consumed in the iniquity of the city, (Gen. xix. 15;) and as the subjects of Abimelech would have been made sinners, had he, in the integrity of his heart, committed adultery with Abraham's wife. (Gen. xx.) That the people of Gerar could have contracted any real guilt from the adultery of their sovereign, or that he, by lying with a woman whom he had reason to believe to be not the wife but the sister of another man, would have incurred all the moral turpitude of that crime, are positions which cannot be maintained. Yet he says, that Abraham had brought upon him and on his kingdom a *great sin;* though it appears, from comparing the 6th verse with the 17th and 18th, that he had not been brought under sin in any other sense than as he was made to suffer for taking Sarah into his house. In this sense, 'Christ, though we are sure that he knew no sin, was made sin for us, and numbered with the transgressors,' because he suffered death for us on the cross; and in this sense it is true, that by the disobedience of Adam all mankind were made sinners, because, in consequence of his offence, they were by the judgment of God made subject to death."

But it may be thought that this interpretation of the word *sin* and *sinners*, though it might perhaps be admitted in the 19th verse, cannot be supposed to give the apostle's real meaning, as it would make him employ in the 12th verse an absurd argument, which has been already noticed. But it may perhaps be possible to get quit of the absurdity, by examining the original text instead of our translation. The words are, *και ὁυτως ἐις παντας ἀνθρωπους ὁ θανατος διηλθεν, ἐφ ᾧ παντες ἡμαρτον.* In order to ascertain the real sense of these words, the first thing to be done is to discover the antecedent to the relative ᾧ. Our translators seem to consider it as used absolutely without any antecedent; but this is inaccurate, as it may be questioned whether the relative was ever used in any language without an antecedent either expressed or understood. Accordingly, the Calvinist critics, and even many Remonstrants, consider *ἑνος ἀνθρωπου* in the beginning of the verse as the antecedent to ᾧ in the end of it, and translate the clause under consideration thus: "And so death hath passed upon all men, in whom (viz. Adam) all have sinned." *Θανατος*, however, stands much nearer to ᾧ than *ἀνθρωπου*; and being of the same gender, ought, we think, to be considered as its real antecedent; but if so, the clause under consideration should be thus translated: "and so death hath passed upon all men, unto which[f] all have sinned," or, as the Arminians explain it, have suffered. If this criticism be admitted as just, ἐφ ᾧ must be considered as standing here under particular emphasis, denoting the utmost length of the consequences of Adam's sin;[g] as if the apostle had said, "so far have the consequences of Adam's sin extended, and spread their influence among mankind, introducing not only a curse upon the earth, and sorrow and toil upon its inhabitants, but even DEATH, UNIVERSAL DEATH, in every part, and in all ages of the world." His words, say the Remonstrants, will unquestionably bear this sense; and it is surely much more probable that it is their true sense, than that an inspired writer should have taught a doctrine subversive of all our notions of right or wrong, and which, if really embraced, must make us incapable of judging when we are innocent and when guilty.

When the apostle says that there is none righteous, no not one, he gives us plainly to understand that he is quoting from the 14th Psalm; and the question first to be answered is, In what sense were these words used by the Psalmist? That they were not meant to include all the men and women then living, far less all that have ever lived, is plain from the fifth verse of the same Psalm, where we are told that those wicked persons "were in great fear, because God was in the congregation of the *righteous*." There was then, it seems, a congregation of righteous persons, in opposition to those called the *children of men*, of whom alone it is said that there was none that did good, no not one. The truth is, that the persons of whom David generally complains in the book of Psalms, constituted a strong party disaffected to his person and government. That faction he describes as proud and oppressive, as devising mischief against him, as violent men continually assembling for war. He styles them his *enemies;* and sometimes characterizes them by the appellation which was given to the apostate descendants of Cain before the deluge. Thus in the 57th Psalm, which was composed when he fled from Saul to the cave in which he spared that tyrant's life, he complains—"I lie among them that are set on fire, even the SONS OF MEN, whose teeth are spears," &c.; and again, in the 58th Psalm, he says, "Do ye indeed speak righteousness, O congregation? Do ye judge uprightly, O ye sons of men?" By comparing these texts with 1 Sam. xxvi. 19, it will appear evident that by the SONS OF MEN mentioned in them, he meant to characterize those enemies who exasperated Saul against him. Now it is well known, that there was a party adhering to the interests of the house of Saul, which continued its enmity to David during the forty years of his reign, and joined with Absalom in rebellion against him only eight years before his death. But it is the opinion of the most judicious commentators, that the 14th Psalm was composed during the rebellion of Absalom; and therefore it is surely much more probable, that by *the children of men*, of whom it is said there is "none that doth good, no not one," the inspired poet meant to characterize the rebels, than that he should have directly contradicted himself in the compass of two sentences succeeding each other. Had he indeed known that all the children of men, as descending from Adam, "are utterly indisposed, disabled, and made opposite to all that is spiritually good, and wholly and continually inclined to all evil," he could not, with the least degree of consistency, have represented the Lord as "looking down from heaven upon them, to see if there were any that did understand and seek after God;" but if by the children of men was meant only the rebel faction, this scenical representation is perfectly consistent, as it was natural to suppose that there might be in that faction some men of good principles misled by the arts of the rebel chiefs.

Having thus ascertained the sense of the words as originally used by the Psalmist, the Arminian proceeds to inquire for what purpose they were quoted by the apostle; and in this inquiry he seems to find nothing difficult. The aversion of the Jews from the admission of the Gentiles to the privileges of the gospel, the high opinion which they entertained of their own worth and superiority to all other nations, and the strong persuasion which they had that a strict obedience to their own law was sufficient to justify them before God, are facts universally known; but it was the purpose of the apostle to prove that all men stood in need of a Redeemer, that Jews as well as Gentiles had been under the dominion of sin, and that the one could not in that respect claim any superiority over the other. He begins his epistle, therefore, with showing the extreme depravity of the heathen world; and having made good that point, he proceeds to prove, by quotations from the books of Psalms, Proverbs, and Isaiah, that the Jews were in nowise better than they, that every mouth might be stopped, and all the world become guilty, or insufficient for their own justification before God.

The next proof brought by the Calvinists in support of their opinion, that all men derive guilt from Adam by ordinary generation, is that text in which St. Paul says that the Ephesians "were by *nature* children of wrath even as others." To this their opponents reply, that the doctrine of original sin is in this verse, as in the last quoted, countenanced only by our translation, and not by the original Greek as understood by the ancient fathers of the Christian church, who were greater masters of that language than we. The words are *και ἠμεν τεκνα φυσει ὀργης*: in which it is obvious, that *τεκνα*, though in its original sense it signifies the genuine children of parents by natural generation, cannot be so understood here; because no man was ever begotten by, or born of, the abstract notion *wrath.* It must therefore be used figuratively; and in other places of scripture it often denotes a close relation to any person or thing. Thus we read of the children of *God*, of the *kingdom*, the *resurrection*, *wisdom*, *light*, *obedience*, and *peace;* whence it is concluded, that by the children of wrath are meant those who are liable to punishment or rejection. And because there were in those days some children, in a lower and less proper sense, by *adoption*, and others, in a higher and more proper sense, by *natural generation*, of whom the relation of the latter to their parents was much closer than that of the former; the apostle tells the Ephesians, that they were by *nature* children of wrath, to convince them that they were *really* liable to it by the strictest and closest relation possible. That the word *φυσει* here is of the same import with *really* or *truly*, and that it does not signify what we mean by *nature* in the proper sense of that word, the ancient fathers are generally agreed, (see Hammond and Whitby on the text, and Suidas on the word *φυσει*); and that the modern Greeks, who still speak a dialect of the noble language of their ancestors, understand the word in the same sense, is apparent from their version of the text before us. In the most correct and elegant edition of the New Testament in their vernacular tongue, the words under consideration are thus rendered; *και φυσικα ἠμασθαν τεκνα ὀργης ὡσαν και ὁι λοιποι*, where it is impossible that *φυσικα* can signify *natural*, otherwise the apostle will be made to say, not that we are by nature derived from Adam liable to wrath, but that we were *naturally begotten* by *wrath* in the abstract. For taking the word *φυσει* in the sense of *really* or *truly*, both the ancient and modern Greeks appear indeed to have the authority of St. Paul himself; who, writing to Timothy, calls him *γνησιον τεκνον*, "his true or genuine son;" not to signify that he was the child of the apostle by natural generation, but that he was closely related to him in the faith to which St. Paul had converted him. That the word *τεκνα φυσει ὀργης* can signify nothing but *truly* or *really relations to wrath*, is still further evident from the

---

[f] That *ἐπι*, when construed with a dative case, often signifies *to* or *unto*, is known to every Greek scholar. Thus *ἐπ' ἐνδοξιᾳ ὁδος*, *the way to fame*, (Lucian.) *Κακουργος ἐπι τῳ θανατῳ*, *a criminal unto death*, (Demosth.) *’Επι θανατῳ συλλαβειν*, *to carry to death or execution*, (Isoc.) *Ὑμεις ἐπ' ἐλευθεριᾳ ἐκληθητε*, *ye have been called to liberty*, (Gal. v. 13.) *Κτισθεντες ἐν Χριστῳ Ἰησου ἐπι ἐργοις ἀγαθοις*, *created in Christ Jesus unto good works*, (Ephes. ii. 10.) See also 1 Thes. iv. 7; 2 Tim. ii. 14; and many other places of the New Testament.

[g] ’Εφ’ ᾡ has likewise this import, denoting the *terminus ad quem* in Phil. iii. 12, and iv. 10.

ground assigned of that relation. It is not the sin of Adam, or the impurity of natural generation, "but the trespasses and sins in which the Ephesians in time past *walked*, according to the course of the world, according to the power of the prince of the air," the spirit that at the time of the apostle's writing "worked in the children of disobedience." Surely no man can suppose that the Ephesians at any time past *walked* in Adam's trespass and sin, or that the prince of the power of the air tempted *them* to eat the forbidden fruit.

Having thus commented on the principal texts which are cited from the New Testament to prove the doctrine of original sin, the Arminians treat those which are quoted from the Old Testament, in support of the same doctrine, with much less ceremony. Thus, when Job says, "who can bring a clean thing out of an unclean? Not one," he is speaking, say they, not of the pravity of our nature, but of its frailty and weakness, of the shortness and misery of human life. The sentence is proverbial; and as it is used only to signify, that nothing can be more perfect than its original, it must, whenever it occurs, be understood according to the subject to which it is applied. That in the place under consideration it refers to our mortality, they think plain from the context; and Dr. Taylor adds, (Scripture Doctrine, part ii.), with some plausibility, that if the words refer to the guilt which we are supposed to derive from Adam, they will prove too much to serve the common scheme of original sin. They will prove that our natural and inherent pravity, so far from rendering us fit objects of wrath, may be urged as a reason why God should not even bring us into judgment; for the patriarch's whole expostulation runs thus, "Dost thou open thine eyes upon such a one, and bringest me into judgment with thee? Who can bring a clean thing out of an unclean?"

The other text, quoted from the same book, they think still less to the purpose; for Eliphaz is evidently contrasting the creature with the Creator; in comparison with whom, he might well say, without alluding to original guilt, "what is man, that he should be clean? and he who is born of a woman, that he should be righteous? Behold he putteth no trust in his saints; yea, the *heavens* are not clean in his sight. How much more abominable and filthy is man, who drinketh iniquity like water?" He does not say, who derives by birth an iniquitous nature; for he knew well, that as we are born, we are the pure workmanship of God, "whose hands have fashioned and formed every one of us;" but "who *drinketh* iniquity like water," who maketh himself iniquitous by running headlong into every vicious practice.

Of the text quoted from the fifty-first psalm in support of the doctrine of original sin, Dr. Taylor labours, by a long and ingenious criticism, to prove that our translators have mistaken the sense. The word which they have rendered *shapen*, he shows to be used once by Isaiah, and twice in the book of Proverbs, to signify *brought forth;* and that which is rendered *conceived me*, is never, he says, employed in scripture to denote human conception. In this last remark, however, he is contradicted by Mr. Parkhurst, who says, (see his Lexicon on the word יחם,) that the LXX constantly render it by κισσαω or ἐγκισσαω, and the Vulgate generally by *concipio*. Without taking upon us to decide between these two eminent Hebrew scholars, we shall only observe, that upon one occasion, (Gen. xxx. 38, 39, 40, compared with xxxi. 10,) it certainly denotes ideas much grosser than those which the Psalmist must have had of his mother's conception; and that there, at least, Dr. Taylor properly translates it, *incalescebant*, adding, "de hoc vero incalescendi genere loqui Davidem nemo sanus existimare potest. Matrem enim incaluisse, aut ipsum calefecisse eo modo quo incalescerent Jacobi pecudes, Regem dicere, prorsus indecorum et absurdum." He contends, however, that the original force of the word is *to be hot*, and that it is applied to *conception*, to *resentment*, to *warmth* by which the body is nourished, to *idolaters* in love with idols, and to the heat of metals. The heat of idolaters, of resentment, and of metals, are evidently foreign to the Psalmist's purpose; and the idea conveyed by the word *incalescere* being set aside for the reasons already assigned, there remains only the warmth by which the body is nourished, and of that warmth by which our author is confident that David spoke.

If this criticism be admitted, the whole verse will then run thus: "Behold I was born in iniquity, and in sin did my mother nurse me;" which has no reference to the original formation of his constitution, but is a periphrasis of his being a *sinner from the womb*, and means nothing more than he was a *great sinner*, or had contracted *early habits* of sin. He no more designed to signify in this verse, that by ordinary generation he had a nature conveyed to him which was "utterly indisposed, disabled, and opposite to all that is spiritually good, and wholly and continually inclined to evil," than he meant in another (Ps. lviii.) to signify strictly and properly that "the wicked are estranged from the womb, and TELL LIES as soon as they are born;" or that Job meant to signify, (Job xxxi. 18), that from the moment he came from his mother's womb he had been a guide to the widow and a succour to the fatherless. All these are hyperbolical forms of expression; which, though they appear strained, and perhaps extravagant, to the phlegmatic inhabitants of Europe, are perfectly suited to the warm imaginations of the orientals, and to the genius of eastern languages. They mean not that Job was *born* with *habits of virtue*, that the wicked actually *walked*, and *spoke*, and *spoke lies* from the instant of their *birth*, or that the Psalmist was really *shapen* in *sin* and *conceived in iniquity*. This last sentence, if interpreted literally, would indeed be grossly impious: it would make the inspired penman throw the whole load of his iniquity and sin from off himself upon *him* who shaped, and upon *her* who conceived him; even upon that God "whose hands had made him and fashioned him, and whom he declares that he will praise for having made him fearfully and wonderfully," and upon that parent who conceived him with sorrow, and brought him forth with pain, and to whom the divine law commanded him to render honour and gratitude. "But if, after all," says Dr. Taylor, (Scripture Doctrine, part ii.) "you will adhere to the literal sense of the text for the common doctrine of *original sin*, show me any good reason why you ought not to admit the literal sense of the text, *this is my body*, for *transubstantiation?* If you say, it is absurd to suppose that Christ speaks of his real natural body; I say, it is likewise absurd to suppose that the Psalmist speaks of his being really and properly shapen in iniquity, and conceived in sin. If you say, that the sense of the words *this is my body*, may be clearly explained by other texts of scripture where the like forms of speech are used; I say, and have shown, that the Psalmist's sense may as clearly and evidently be made out by parallel texts, where you have the like kind of expression. If you say that transubstantiation is attended with consequences hurtful to piety, I say that the common doctrine of original sin is attended with consequences equally hurtful; for it is a principle apparently leading to all manner of iniquity, to believe that sin is natural to us, that it is interwoven and ingrafted into our very constitution from our conception and formation in the womb."

Thus far the Arminians of the present day are agreed in opposing the doctrine of the rigid Calvinists, and in stating their own notions of the consequences of Adam's fall; but from that event their adversaries deduce one consequence, which some of them admit and others deny. It is said that though we cannot possibly be partakers in Adam's guilt, we yet derive from him a moral taint and infection, by which we have a natural propensity to sin; that having lost the image of God, in which he was created, Adam begat sons in his own image; and in one word, that the sensual appetites of human nature were inflamed, and its moral and intellectual powers greatly weakened, by the eating of the forbidden fruit. The heathens themselves acknowledged and lamented this depravity, though they were ignorant of the source from which it sprung. The scriptures assert it, affirming that no man can be born pure and clean; that whatever is born of the flesh, or comes into the world by ordinary generation, is flesh, carnal and corrupt; that the imagination of the thoughts of man's heart is only evil continually; that the heart is deceitful above all things and desperately wicked; and that out of it proceeds all that is vile and sinful. (Job xiv. 4.)

We have thus given as full and comprehensive a view as our limits will permit of the different opinions of the Calvinists and Arminians respecting the consequences of Adam's fall. If we have dwelt longer upon the scheme of the latter than of the former, it is because every Arminian argument is built upon criticism, and appeals to the original text; while the Calvinists rest their faith upon the plain words of scripture as read in our translation. If we might hazard our own opinion, we should say that the truth lies between them, and that it has been found by the moderate men of both parties, who, while they make use of different language, seem to us to have the same sentiments. That all mankind really sinned in Adam, and are on that account liable to most grievous torments in soul and body, without intermission, in hell fire for ever, is a doctrine which cannot be reconciled to our natural notions of God. On the other hand, if human nature was not somehow debased by the fall of our first parents, it is not easy to account for the numberless phrases in scripture which certainly seem to speak that language, or for the very general opinion of the Pagan philosophers and poets respecting the golden age and the degeneracy of man. Cicero, in a quotation preserved by St. Augustin from a work that is now lost, has these remarkable words, "Homo non ut a matre sed ut a noverca natura editus est in vitam, corpore nudo, et fragili, et infirmo; animo autem anxio ad molestias, humili ad timores, molli ad labores, prono ad libidines; in *quo tamen inest tanquam obrutus quidam divinus ignis ingenii et mentis.*" (Vide D. Aug. lib. iv. contra Pelagium.) Nor do we readily perceive what should induce the more zealous Arminians to oppose so vehemently this general opinion of the corruption of human nature Their desire to vindicate the justice and goodness of God, does them honour; but the doctrine of inherent corruption detracts not from these attributes; for what we have lost in the first Adam has been amply supplied to us in the second; and we know from the highest authority, that the duties required of us are in proportion to our ability, since we are told, that "unto whomsoever much is given, of him shall much be required."

Woods's Essay on Native Depravity. Boston, U. S., 1835. The work of Edwards is an answer, and a most able answer, to that of Taylor.

PART III.—DOCTRINES CONCERNING THE SCHEME OF HUMAN REDEMPTION.

The deliverance of man from the penal consequences of his sin, and his moral renovation in the sight of God, are effected by his cordially and intelligently accepting a gracious pardon offered to him by God, through the meritorious atonement and intercession of Jesus Christ. See John iii. 14—17, 36; x. 9, 28. Rom. viii. 11; v. 1; iv. 5, &c.

SECT. I. *Of the Person of Christ.*

The Scriptures distinctly inform us that our Saviour Jesus Christ, united in his own person the human nature and the divine; *i. e.* was a real man having a human body and a human soul, and yet at the same time being God. Whilst on the one hand we are told of his birth by a human mother; of his *growing* in wisdom and stature, (Luke ii. 52); of his being hungry, thirsty, and weary, (John iv. 6, 10); of his suffering and dying, all which are attributes of humanity; we are on the other assured, that he was in a proper and peculiar sense the Son of God, (John i. 34; iii. 18); that in him dwelt all the fulness of the Godhead bodily, (Col. ii. 9); that he was God over all blessed for ever, (Rom. ix. 5); that he was God manifest in the flesh, (1 Tim. iii. 16); that he is the Creator of the universe, and will be the final omniscient judge of the quick and the dead; and that he is equally with the Father the proper object of worship and religious homage, (John i. 1—3. Col. i. 16, 17. Acts xvii. 31. 2 Tim. iv. 1. 1 Thes. iii. 11—13. Rev. v. 5—14.)

Obs. 1. See Smith's Scripture Testimony to the Messiah, 3 vols. Wardlaw's Discourses on the Socinian Controversy, Dis. iii—vi. Wynperse's Demonstration of the Divinity of our Lord, by Alexander. Urwick's Vindication of our Saviour's Divine Right to Worship.

Obs. 2. This incarnation of the Son of God is perhaps the greatest mystery of the Christian faith, and that to which ancient and modern heretics have urged the most plausible objections. The doctrine of the Trinity is indeed equally incomprehensible; but the nature of God and the mode of his existence, as revealed in scripture, no man, who thinks, can be surprised that he does not comprehend; for a revelation which should teach nothing mysterious on such a subject, would be as incredible and as useless as another which contained nothing but *mystery.* The difficulty respecting the incarnation which forces itself on the mind, is not how two natures so different as the divine and human can be so intimately united as to become one person; for this union in itself is not more inconceivable than that of the soul and body in one man; but that which at first is apt to stagger the faith of the reflecting Christian, is the infinite distance between the two natures in Christ, and the comparatively small importance of the object, for the attainment of which the eternal Son of God is said to have assumed on him our nature.

Upon mature reflection, however, much of this difficulty will vanish to him who considers the ways of Providence, and attends to the meaning of the words in which this mystery is taught. The importance of the object for which the Word condescended to be made flesh, we cannot adequately know. The oracles of truth indeed inform us, that Christ Jesus came into the world to save sinners; but there are passages scattered through the New Testament (Eph. i. 10; Col. i. 19, 20,) which indicate, not obscurely, that the influence of his sufferings extends to other worlds beside this: and if so, who can take on him to say, that the quantity of good which they may have produced, was not of sufficient importance to move even to this condescension a Being who is emphatically styled LOVE?

But let us suppose that everything which he did and taught and suffered was intended only for the benefit of man, we shall, in the daily administration of providence, find other instances of the divine condescension; which, though they cannot be compared with the incarnation of the second person in the blessed Trinity, are yet sufficient to reconcile our understandings to that mystery when revealed to us by the Spirit of God That in Christ there should have dwelt on earth "all the fulness of the Godhead bodily," (Col. ii. 9,) is indeed a truth by which the devout mind is overwhelmed with astonishment; but it is little less astonishing that the omnipotent Creator should be intimately present at every instant of time to the meanest of his creatures, "upholding all things, the vilest reptile as well as the most glorious angel, by the word of his power," Heb. i. 3. Yet it is a truth self-evident, that without this constant presence of the Creator, nothing which had a beginning could continue one moment in being; that the visible universe would not only crumble into chaos, but vanish into nothing; and that the souls of men, and even the most exalted spirits of creation, would instantly lose that existence, which, as it was not of itself, and is not necessary, must depend wholly on the will of Him from whom it was originally derived. (See METAPHYSICS and PROVIDENCE.)

In what particular way God is present to his works, we cannot know. He is not diffused through the universe like the *anima mundi* of the ancient Platonists, or that modern idol termed the *substratum of space*, (see METAPHYSICS); but that he is in power as intimately present now to every atom of matter as when he first brought it into existence, is equally the dictate of sound philosophy and of divine revelation; for "in him we live and move and have our being;" and power without substance is inconceivable. If then the divine nature be not debased, if it cannot be debased by being constantly present with the vilest reptile on which we tread, why should our minds recoil from the idea of a still closer union between the second person of the ever blessed Trinity, and the body and soul of Jesus Christ? The one union is indeed different from the other, but we are in truth equally ignorant of the nature of both. Reason and revelation assure us that God must be present to his works to preserve them in existence; and revelation informs us further, that one of the persons in the Godhead assumed human nature into a personal union with himself, to redeem myriads of rational creatures from the miserable consequences of their own folly and wickedness. The importance of this object is such, that, for the attainment of it, we may easily conceive that he who condescends to be potentially present with the worms of the earth and the grass of the field, would condescend still further to be personally present with the spotless soul and body of a man. Jesus Christ lived indeed a life of poverty and suffering upon earth, but his divine nature was not affected by his sufferings. At the very time when, as a man, he had not a place where to lay his head; as God, he was in heaven as well as upon earth, (John iii. 13,) dwelling in light inaccessible; and while, as a man, he was increasing in wisdom and stature, his divinity was the fulness of him who filleth all in all, and from whom nothing can be hid.

Sect. II. *Of the Life and Teaching of Christ.*

What men earnestly wish to be true, they readily believe. Hence the Jewish people, losing sight of the yoke under which they and the whole human race were brought by the fall of Adam, mistaking the sense of the blessing promised to all nations through the seed of Abraham, and devoting their whole attention to the most magnificent descriptions of the Messiah's kingdom, expected in him a prince who should conquer the Romans, and establish on earth a universal monarchy, of which Jerusalem was to be the metropolis.

As our Saviour came for a very different purpose, the first object of his mission was to rectify the notions of his erring countrymen, in order to fit them for the deliverance which they were to obtain through him. Accordingly, when he entered on his office as a preacher of righteousness, he embraced every opportunity of inveighing against the false doctrines taught as traditions of the elders; and by his knowledge of the secrets of all hearts, he exposed the vile hypocrisy of those who made a gain of godliness. The Jews had been led, by their separation from the rest of the world, to consider themselves as the peculiar favourites of Jehovah; and the consequence was, that, contrary to the spirit of their own law, and the explicit doctrines of some of their prophets, they looked on all other nations with abhorrence, as on people physically impure. These prejudices the blessed Jesus laboured to eradicate. Having desired a lawyer, by whom he was tempted, to read that part of the law of Moses which commanded the Israelites to love their neighbours as themselves, he compelled him, by means of a parabolical account of a compassionate Samaritan, to acknowledge, that under the denomination of neighbour, the divine lawgiver had comprehended all mankind as the objects of love, (St. Luke x. 25—38.) The importance in which Moses held the ritual law, and to which, as the means of preserving its votaries from the contagion of idolatry, it was justly entitled, had led the Jews to consider every ceremony of it as of intrinsic value and perpetual obligation: but Jesus brought to their recollection God's declared preference of mercy to sacrifice; showed them that the weightier matters of the law, judgment, mercy, and faith, claimed their regard in the first place, and its ceremonial observances only in the second; and taught them in conformity with the predictions of their own prophets, (Jeremiah xxxi. 31, &c.) that the hour was about to come when the worship of God should not be confined to Jerusalem, but that "true worshippers should everywhere worship the Father in spirit and in truth," (John iv. 25—27.)

It being the design of Christ's coming into the world to break down the middle wall of partition between the Jews and Gentiles, and to introduce a new dispensation of religion which should unite all mankind as brethren in the worship of the true God, and fit them for the enjoyment of heaven; he did not content himself with merely restoring the moral part of the Mosaic law to its primitive purity, disencumbered of the corrupt glosses of the scribes and pharisees, but added to it many spiritual precepts, which, till they were taught by him, had never occurred to either Jew or Gentile. The Hebrew lawgiver had prohibited murder under the penalty of death; but Christ extended the prohibition to causeless anger, and to contemptuous treatment of our brethren, commanding his followers, as they valued their everlasting salvation, to forgive their enemies, and to love all mankind. Adultery was forbidden by the law of Moses as a crime of the deepest dye; but Jesus said to his disciples, "that whosoever looketh on a woman to lust after her, hath committed adultery with her already in his heart," and is of course liable to the Divine vengeance. The *lex talionis* was in force among the Jews, so that the man who had deprived his neighbour of an eye or a tooth, was to suffer the loss of an eye or a tooth himself; but this mode of punishment, which inflicted *blemish* for *blemish*, though suited to the hardness of Jewish hearts, being inconsistent with the mild spirit of Christianity, was abolished by our blessed Lord, who severely prohibited the indulgence of revenge, and commanded his followers to love even their enemies. Perjury has in every civilised nation been justly considered as a crime of the highest atrocity, and the Mosaic law doomed the false witness to bear the punishment, whatever it might be, which he intended, by swearing falsely, to bring on his brother; but the author of the Christian religion forbade not only false swearing, but swearing at all, except on solemn occasions, and when an oath should be required by legal authority.

By thus restoring the law to its original purity, and in many cases extending its sense, the blessed Jesus executed the office of a Prophet to the lost sheep of the house of Israel; but had he not been more than an ordinary prophet, he could not have abrogated the most trivial ceremony of it, nor even extended the sense of any of its moral precepts; for their great lawgiver had told them, that "the Lord their God would raise up unto them but one prophet, like unto him, to whom they should hearken," (Deut. xviii. 15.) That prophet was by themselves understood to be the Messiah, whom they expected to tell them all things. It was necessary therefore that Jesus, as he taught some new doctrines, and plainly indicated that greater changes would soon be introduced, should vindicate his claim to that exalted character which alone could authorise him to propose innovations. This he did in the amplest manner, by fulfilling prophecies and working miracles, (see Miracle and Prophecy); so that the unprejudiced part of the people readily acknowledged him to be of a truth "that prophet which should come into the world—the Son of God, and the King of Israel." He did not, however, make any change in the national worship, or assume to himself the smallest civil authority. He had submitted to the rite of circumcision, and strictly performed every duty, ceremonial as well as moral, which that covenant made incumbent on other Jews; thus fulfilling all righteousness. Though the religion which he came to propagate was in many respects contrary to the ritual law, it could not be established, or that law abrogated, but in consequence of his death, which the system of sacrifices was appointed to prefigure; and as his kingdom, which was not of this world, could not commence till after his resurrection, he yielded during the whole course of his life a cheerful obedience to the civil magistrate, and wrought a miracle to obtain money to pay the tribute that was exacted of him. Being thus circumstanced, he chose from the lowest and least corrupted of the people certain followers, whom he treated with the most endearing familiarity for three years, and commissioned at his departure to promulgate such doctrines as, consistently with the order of the divine dispensations, he could not personally preach himself. With these men, during the course of his ministry on earth, he went about continually doing good, healing the sick, casting out devils, raising the dead, reproving sin, preaching righteousness, and instructing his countrymen, by the most perfect example which was ever exhibited in the world, of whatsoever things are true, or honest, or just, or pure, or lovely, or of good report. The scribes and pharisees, however, not finding him that conqueror whom they vainly expected, becoming envious of his reputation among the people, and being filled with rancour against him for detecting their hypocritical arts, delivered him up to the Roman governor, who, though convinced of his innocence, yielded to the popular clamour, and crucified him between two thieves, as an enemy to Cæsar.

Sect. III.—*Of the Death of Christ.*

When our Lord was hanging upon the cross, and just before he expired, he said, It is finished, intimating that the purpose was now fulfilled for which he had come into the world, and which, as he had formerly told his disciples, "was not to be ministered unto, but to minister, and to give his life a ransom for many," (Matt. xx. 28). For his blood, as he assured them at the institution of the Eucharist, "was to be shed for the remission of sins." That Christ died voluntarily for us, the just for the unjust, and that "there is none other name under heaven given among men whereby we must be saved," is the uniform doctrine of the prophets who foretold his coming, of John the Baptist, who was his immediate harbinger, and of the apostles and evangelists who preached the gospel after his ascension into heaven. Thus Isaiah says of the Messiah (chap. liii. 5, 6, 8, 10, 12), that "he was wounded for our transgressions, and bruised for our iniquities; that the chastisement of our peace was upon him, and that with his stripes we are healed; that we had all like sheep gone astray, turning every one to his own way, and that the Lord laid on him the iniquity of us all; that he was cut off out of the land of the living, and stricken for the transgression of God's people; and his soul or life was made an offering for sin; and that he bore the sin of many, and made intercession for the transgressors." The Baptist, "when he saw Jesus coming unto him, said to the people, Behold the Lamb of God, which taketh away the sin of the world," (John i. 29); plainly intimating that his death was to be a sacrifice, since it was only as a sacrifice that the Jews could form any conception of a lamb taking away sin. The epistles of St. Paul are so full of the doctrine of Christ's satisfaction, that it is needless to quote particular texts in proof of it. He tells the Romans, that Jesus Christ was "set forth to be a propitiation through faith in his blood; he was delivered for our offences, and raised again for our justification; that he died for the ungodly; and that God commendeth his love towards us, in that while we were yet sinners Christ died for us," (chap. iii. 25; iv. 25; v. 6, 8). He assures the Corinthians that Christ died for all; that "they who live should not henceforth live unto themselves, but to him who died for them and rose again; and that God made him to be sin for us, who knew no sin, that we might be made the righteousness of God in him," (2 Ep. v. 15, 21). He informs the Galatians, that Christ "gave himself for our sins, that he might deliver us from this present evil world, according to the will of God and our Father; and that he redeemed us from the curse of the law, being made a curse for us," (chap. i. 4). St. Peter and St. John speak the very same language; the former teaching us, that "Christ suffered for us, and bare our sins in his own body on the tree," (1 Peter ii. 21 and 24); the latter, "that the blood of Jesus Christ cleanseth us from all sin, and that he is the propitiation for our sins; and not for our sins only, but also for the sins of the whole world," (1 John i. 7; ii. 2). That he came into the world for the purpose of suffering, appears from his own words: for "no man," said he, (John x. 18), "taketh my life from me, but I lay it down of myself: I have power to lay it down, and I have power to take it again. This commandment have I received from my Father." And that he voluntarily laid it down for mankind, is evident from his calling himself the Good Shepherd, and adding, that "the Good Shepherd giveth his life for the sheep." (John x. 11.)

Sect. IV.—*Of the nature of that benefit which Man derives from the propitiatory work of Christ.*

That Christ died for the benefit of the human race, is a truth so apparent from Scripture, that no man professing Christianity has hitherto called it in question; though very different opinions have been formed, even by pious men, concerning the nature and extent of that benefit, and the means by which it is applied. Of these opinions we shall endeavour to give an impartial account, and as fully as our limits will permit.

The strictest adherents to the theological system of Calvin, interpreting literally such texts of Scripture as speak of Christ's being *made sin* for us, of his *bearing our sins in his own body on the tree*, and of the Lord's *laying on him the iniquity of us all*, contend, that the sins of the elect were lifted off from them and laid on Christ by *imputation*, much in the same way as they think the sin of Adam is imputed to his posterity. "By bearing the sins of his people," says Dr. Gill, (Body of Divinity, vol. ii. book iii. chap. v. § 4), "he took them off from them, and took them upon himself, bearing or carrying them, as a man bears or carries a burden on his shoulders. There was no sin *in* him inherently, for if there had, he would not have been a fit person to make satisfaction for it; but sin was put upon him by his Divine Father, as the sins of the Israelites were put upon the scape-goat by Aaron. No creature could have done this; but the Lord hath laid on him, or made to meet on him, the iniquity of us all, not a single iniquity, but a whole mass and lump of sins collected together, and laid as a common burden upon him, even the sins of all the elect of God. This phrase of laying sin on Christ is expressive of the *imputation* of it to him; for it was the will of God not to impute the transgressions of his elect to themselves, but to Christ, which was done by an act of his own; for he hath made him to be sin for us; that is, by *imputation*, in which way we are made the righteousness of God in him; that being imputed to us by him as our sins were to Christ. The sense is, a charge of sin was brought against him as the surety of his people. He was numbered with the transgressors; for bearing the sins of many, he was reckoned as if he had been a sinner himself, sin being *imputed* to him; and he was dealt with as such. Sin being found upon him by *imputaton*, a demand of satisfaction for sin was made, and he answered it to the full. All this was with his own consent. He *agreed* to have sin laid upon him, and *imputed* to him, and a charge of it brought against him, to which he engaged to be responsible; yea, he himself took the sins of his people upon him; so the evangelist Matthew has it, "He himself took our infirmities, and bare our sicknesses," (chap. viii. 17). As he took the nature of men, so he took their sins, which made his flesh to have *the likeness of sinful flesh*, though it really was not sinful. What Christ bore being laid upon him, and imputed to him, were *sins* of all sorts, original and actual; sins of every kind, open and secret, of heart, lip, and life; all acts of sin committed by his people, for he has redeemed them from all their iniquities; and God, for Christ's sake, forgives all trespasses, his blood cleanses from all sin, and his righteousness justifies from all; all being imputed to him as that is to them. Bearing sin supposes it to be a burden; and indeed it is a burden too heavy to bear by a sensible sinner.[1] When sin is charged home upon the conscience, and a saint groans, being burdened with it, what must that burden be, and how heavy the load which Christ bore, consisting of all the sins of all the elect from the beginning of the world to the end of it; and yet he sunk not, but stood up under it; failed not, nor was he discouraged, being the mighty God, and the Man of God's right hand, made strong for himself."

To the Arminians or Remonstrants, this doctrine of the imputation of the sins of men to the Son of God appears as absurd as the similar doctrine of the imputation of the sin of Adam to his unborn posterity; and it is certainly attended with consequences which have alarmed serious Christians of other denominations.

Were it possible in the nature of things, says the Arminian, to transfer the guilt of one person to another, and to lay it upon him as a burden, it could not be done without violating those laws of equity which are established in the Scripture and engraven on the human heart. But this is not possible. To talk of lifting masses of sin, or transferring them like burdens from the guilty to the innocent, is to utter jargon, says he, which has no meaning; and we might with as much propriety speak of lifting a scarlet colour from a piece of cloth and laying it on the sound of a trumpet, as of literally lifting the sins of the elect from them and laying them on Christ. Guilt is seated on the mind; and no man can become a sinner but by an act of volition. If Christ therefore *really* took upon him the sins of his people, he must have deliberately formed a wish to have actually *committed* all these sins; but such a wish, though it would have made him inherently guilty, and therefore incapable of satisfying for sin, could not have cancelled deeds that were done before he was born, or have made those innocent who really had been sinners. A deed once done cannot be undone; a volition which has been formed cannot be annihilated. By sincere repentance, the habitual dispositions are indeed changed, and those who have been sinners become objects of mercy; but no power can recal the hours that are past, or make those actions which have been performed to have been not performed. To remove guilt from the sinner and lay it on the innocent may, therefore, be safely pronounced impossible even for Omnipotence itself, for it implies that a thing may be and not be at the same instant of time; and the doctrine which teaches that this removal was made from the elect to Christ, is an imagination of yesterday, which has no countenance from Scripture, and is contrary to the established constitution of things. Those who imagine that guilt may be propagated from father to son, have something like an argument to urge for the imputation of Adam's sin to his numberless posterity; for all the men and women who have by ordinary generation been introduced into the world, have undoubtedly derived their nature from the primeval pair. But Christ did not derive his nature from the *elect*, that their sins should be communicated to him; nor, as he was miraculously conceived by the Holy Ghost, can we attribute to him any degree of that *taint* which is supposed to have been conveyed from Adam to all the other generations of men.

Nothing more, therefore, can be meant by "Christ's being made sin for us," and "bearing our sins in his own body on the tree," or by God's "laying upon him the iniquity of us all," than that by his sufferings we are freed from the punishment of our sins; it being in Scripture a common figure of speech, as even Dr. Gill has somewhere acknowledged, to denote by the word *sin* the *consequences* of sin. That this figure is used in those texts from which he infers that Christ took the sins of the elect on himself, is evident from the verse which he quotes from the gospel of St. Matthew; in which it is said, that "himself took our infirmities and bore our sicknesses." The sicknesses and infirmities there alluded to are the leprosy, the palsy, the fever, and demoniacal possessions; but when our blessed Lord cured these diseases, surely he did not by his omnipotent word lift them off from the patients and take them on himself, so as actually to become a leper, a paralytic, and a dæmoniac, or even to be reckoned as such either by the multitude, or by the priest, whose duty it was to take cognizance of every illegal uncleanness, (Levit. xiii). And if his inveterate enemies did not *impute* to him the leprosy when he removed that plague from others, why should it be supposed that his own Father, to whom he was at all times well-pleasing, imputed to him the sins of which, by his sufferings, he removed the punishment from those who were guilty? To impute to a person any action, whether virtuous or vicious, which he did not perform, can proceed only from ignorance, or malice, or partiality; but God is no respecter of persons, and from ignorance and malice he is removed to an infinite distance. It is indeed an undoubted truth, that "the Lord Jesus, by his perfect obedience and sacrifice of himself, which he through the eternal Spirit once offered up unto God, hath fully satisfied the justice of his Father; and purchased not only reconciliation, but an everlasting inheritance in the kingdom of heaven for all those whom the Father hath given him," (Confession of Faith, chap. viii. § v.); but that he actually took on himself the sins of mankind, or that those sins were imputed to him by God, who punished him as a person whom he considered as guilty, is a doctrine equally injurious to the justice of the Father and to the immaculate purity of the Son.

To this imaginary transferring of virtues and vices from one person to another, as the Scriptures give no countenance, so they nowhere call the death of Christ a *satisfaction* for the sins of men. The term has indeed been long in use among divines, and when properly explained it may be retained without any danger; but in treating of this subject, it would perhaps be more prudent to restrict ourselves to the use of Scripture language, as the word *satisfaction* carries in it the ideas of a debt paid and accepted; whereas it is said by St. Paul, that "eternal life is the *gift* of God through Jesus Christ our Lord; and that we are justified *freely by his grace* through the redemption that is in Jesus Christ, whom God hath set forth to be a propitiation through faith in his blood," (Rom. vi. 23; iii. 24, 25).

To clear up this matter, and attain adequate notions of redemption, it will be necessary to look back to the fall of our first parents; for the great purpose for which Christ was promised, and for which he came into the world, was, by bruising the head of the serpent, to restore mankind to the inheritance which they had lost through the transgression of Adam. This is apparent not only from the original promise made to the woman, but also from different passages in the epistles of St. Paul, who expressly calls Christ the second Adam, and says, that, "as by the offence of one, judgment came upon all men to condemnation; even so by the righteousness of one, the free gift came upon all men unto justification of life;" that, "as by one man's disobedience many were made sinners, so by the obedience of one shall many be made righteous;" and that, "as in Adam all die, even so in Christ shall all be made alive," (Rom. v. 18, 19; 1 Cor. xv. 22.) Hence it was that John the Baptist, when he saw Jesus coming to him, said to his disciples, "Behold the Lamb of God which taketh away, not the *sins*, but the *sin* of the world," (John i. 23), evidently alluding to Adam's sin and its consequences, since no other sin was ever committed of which the consequences extend to the whole world.

---

[1] By the phrase *a sensible sinner*, the learned author means a sinner who is conscious of guilt and ill desert as a transgressor of the divine law.

This being the case, it is undeniable, that whatever we lost in the first Adam is restored to us by the second; and therefore they who believe that the punishment denounced against eating the forbidden fruit was death *corporal, spiritual*, and *eternal*, must believe that we are redeemed from all these by Christ; who having "appeared once in the end of the world to put away sin by the sacrifice of himself, died for us, that whether we wake or sleep, we should live together with him," (Heb. ix. 26. 1 Thess. v. 10). If the image of God in which man was created was lost by the breach of the first covenant, it is more than restored to us "by the Mediator of a better covenant, which is established upon better promises;" if by the sin of Adam we were utterly indisposed, disabled, and made opposite to all that is spiritually good, and wholly inclined to all evil, and that continually, we are freed from that dreadful curse by "our Saviour Jesus Christ, who gave himself for us, that he might redeem us from all iniquity, and purify to himself a peculiar people zealous of good works," (Titus ii. 14); and if for our share in the first transgression we be justly liable to all punishments in this world and in that which is to come, the apostle assures us, that "when we were enemies we were reconciled to God by the death of his Son, because that God was in Christ reconciling the world to himself, not imputing their trespasses unto them," (Rom. v. 10. 2 Cor. v. 19). As Jesus is "the Lamb slain (in the divine decree) from the foundation of the world," these beneficial consequences of his death have been extended by a retrospective view to all in every age whose names are written in the book of life, though it be absurd to suppose that he literally took their sins upon him, and impious to imagine that he suffered under the imputation of sin.

SECT. V.—*Of the extent of that benefit which Christ procured for Man.*

It is well known to be one of the fundamental doctrines of the Calvinistic school, that "none are *redeemed* by Christ, effectually called, justified, adopted, sanctified, and saved, but the elect only," (Confession of Faith of the Church of Scotland, chap. iii. § 6); and if the notions of redemption which, in the end of the 17th century, were very generally embraced, be admitted as just, it will not be easy to overturn the arguments by which that doctrine is supported. Such of them as are connected with the great question of election and reprobation, and enter into the decision of it, we have stated in another place (see PREDESTINATION); but it is farther argued, (Gill's Body of Divinity, vol. ii. book iii. chap. 3), that the doctrine of *universal* redemption reflects on the wisdom, the justice, and the power of God, and robs him of his glory.

The Scriptures assure us that all men shall not be saved; but how can this be, if Christ died for all, and the scheme of salvation, by his death, was formed by infinite wisdom? The Arminians indeed say, that those who fail of salvation, fail through their own fault in not performing the conditions required of them; but God either knew or knew not that such men would not perform those conditions. If he knew it not, his knowledge is limited; if he did know it, where was his wisdom in providing a scheme of redemption for men to whom he was aware that it would be of no benefit? "God," we are told, "is righteous in all his ways, and holy in all his works;" but there is no righteousness in making Christ bear the sins of *all* men, and suffer the punishment due to them, if any one of those men shall be afterwards punished everlastingly. If Christ has already paid the debts of the whole world, it cannot be just to cast a single inhabitant of the whole world into the prison of hell, there to be detained till he shall again have paid the uttermost farthing. "The Lord's hand is not shortened that it cannot save;" for he is and always will be the same Almighty power that he was from eternity; but if by the divine decree Christ died for all men, and yet all men shall not be saved, it would appear that man is mightier than his Maker. The ultimate end of God in the redemption of man is admitted to have been his own glory; but if any individual of the human race, who was redeemed by Christ, shall not be saved, God will so far lose his end, and be deprived of his glory. For, if this were the case, where would be the glory of God the Father in forming a scheme which, with respect to multitudes, does not succeed; and where would be the glory of the Son of God, the Redeemer, in working out the redemption of men who are yet not to be saved by him? and where would be the glory of the Spirit of God, if redemption were not by him effectually applied to every individual for whom it was wrought? By such arguments as these do the Calvinists oppose the scheme of universal redemption, and contend that Christ died only for the *elect*, or such as shall be placed on his right hand at the day of judgment. This notion of a limited redemption, as they think it more worthy of the sovereignty of God, they believe to be taught by our Saviour himself, when he saith, (John vi. 37–40), "All that the Father *giveth* me shall come to me; and him that cometh to me, I will in no wise cast out. For I came down from heaven, not to do my own will, but the will of him that sent me. And this is the Father's will who hath sent me, that of all which he hath *given* me I should lose nothing, but should raise it up again at the last day."

The Arminians, on the other hand, contend that it is impious to limit the effects of Christ's death to a chosen few, since it appears from Scripture, that by the decree and intention of his Father he tasted death for every man, that all, without exception, might through him obtain remission of their sins. Thus our Lord himself told Nicodemus, (John iii. 14–18), that "as Moses lifted up the serpent in the wilderness, even so must the Son of Man be lifted up; that *whosoever* believeth in him, should not perish, but have everlasting life. For God so loved the *world*, that he gave his only begotten Son, that whosoever believeth in him should not perish, but have everlasting life. For God sent not his Son into the world to condemn the world, but that the *world* through him might be saved." In perfect conformity with the doctrine of his divine Master, St. Paul teaches, (2 Cor. v. 14–20. 1 Tim. ii. 4–7. Heb. ii. 9), that "Christ died for *all;* that God was in Christ reconciling the *world* to himself, not imputing their trespasses unto them;" that "he will have *all* men to be saved, and to come into the knowledge of the truth;" that "Christ gave himself a ransom for *all;*" and that "Jesus was made a little lower than the angels, that by the grace of God he should taste death for *every man.*" The very same thing is taught by St. Peter and St. John, when the former says, (2 Peter iii. 9), that "the Lord is not willing that *any* should perish, but that *all* should come to repentance;" and the latter, (1 John ii. 2), that "Jesus Christ the righteous is the propitiation for our sins; and not for our's only, but for *the whole world.*"

On these texts, without any commentary, the Arminians are willing to rest their doctrine of universal redemption; though they think that a very strong additional argument for its truth arises from the numberless absurdities which flow from the contrary opinion. Thus, say they, (Limborch's Theologia Christiana, Eng. Trans. book iv. chap. iii.) the apostles were commanded by our Saviour (St. Mark xvi. 15, 16), to "go into *all* the world and preach the gospel to *every creature*," and all who hear it preached are required to believe it: but no man, as the Calvinists themselves confess, can believe the gospel as a Christian, without believing that Christ *died for him;* and, therefore, if it be true that Christ died only for the *elect*, a great part of mankind are required to believe a lie, and a falsity is made the object of divine faith! Again, if Christ did not die for *all*, then no man can be sure that he is bound to believe in Christ when preached to him; nor can any man be justly condemned for infidelity; which is not only absurd in itself, but directly contrary to what we are taught by our blessed Lord, who assures us, (St. John iii. 18, 19, and 36; Rom. xiv. 9), that unbelief is the cause of condemnation. Lastly, if Christ died not for *all*, then it is certain that he cannot claim dominion *over all* in *consequence* of his *death* and *resurrection;* but St. Paul says expressly, that "to *this end* Christ both *died*, and *rose*, and *revived*, that he might be the Lord of the *dead* and *living*." The Arminians acknowledge, that though Christ died for all, there are many who will not be saved; for, say they, (Wells's Divine Laws and Covenants, part ii. chap. iii.) the death of Christ did not literally pay the debts incurred by sinners, but only obtained for them the gracious covenant of the gospel, by which all who believe in him, and sincerely endeavour to work out their own salvation with fear and trembling, are entitled to forgiveness of sins and eternal life.

SECT. VI.—*Of the Resurrection and Ascension of Christ.*

The Apostles of Christ, in announcing his religion to men, laid great emphasis on the fact of their Master's resurrection from the dead, as that which proved the divinity of his mission, and the acceptance of his work by God. That this fact really occurred, there can be no doubt. It may be laid down as a fixed principle, that no man, or body of men, will deliberately choose *evil* for its *own sake*, or enter zealously upon a tedious and difficult enterprise, from which no good can possibly arise, and from which unmixed misery is clearly foreseen as the necessary result of every step of the progress. Such, however, must have been the choice and the conduct of the apostles, when they resolved to preach a new religion founded on the resurrection of Jesus, if they did not certainly know that Jesus had risen from the dead. And this conduct must have been adopted, and, in opposition to every motive which can influence the human mind, have been persevered in by a great number of men and women, without the smallest contradiction having ever appeared in the various testimonies, which at different times, and under the cruelest tortures, they all gave to a variety of circumstances, of which not one had its foundation in truth. He who can admit this supposition, will not surely object to the credibility of miracles. The resurrection of a man from the dead is an event so different indeed from the common course of things, that nothing but the most complete evidence can make it an object of rational belief; but as the resurrection of Jesus has always been said to have had God for its Author, it has an effect which does not exceed the power of the cause assigned, and is therefore an event possible in itself and capable of proof. It is a deviation from the laws of nature, but it is not contradictory to any one of those laws. That a great number of men and women should deliberately form a plan of ruin and misery to themselves, without a prospect of the smallest advantage either in this world or the next, is as different from the common course of things as the resurrection from the dead; and therefore in itself at least as great a miracle: but that they should persist in prosecuting this plan in the midst of torments; that they should spread themselves over the whole world, and everywhere publish a number of falsehoods, without any one of them contradicting the rest; that truth should never escape them either in an unguarded moment, or when lingering on the rack, and yet all their lies should be in perfect agreement with each other; that they should every one of them court sufferings for a person whom they knew to be an impostor; that not one of the number—not even a single woman—should have so much compassion for a fellow-creature, as to rescue him from the flames by confessing a truth which could injure nobody—not even the suffering deceivers themselves;—all this is not only different from the common course of things, but directly contrary to the most known laws of nature, and is therefore not miraculous, but may be pronounced impossible. Yet this impossibility we must admit, or acknowledge, that as Christ died for our sins, according to the Scriptures, and was buried, so he arose again the third day, according to the Scriptures; and was seen of Cephas, then of the twelve; after that of above five hundred brethren at once; after that of James; and then of all the apostles; and that he was last of all seen of St. Paul, (1 Cor. xv. 3–9,) who by the vision was converted to preach the faith which till then he had persecuted.

Thus we are assured, that "those who have fallen asleep in Christ are not lost, since he has risen from the dead, and become the first fruits of them that slept. For since by man came death, by man also came the resurrection of the dead. For as in Adam all die, even so in Christ shall all be made alive. But every man in his own order; Christ the first-fruits, afterwards they that are Christ's at his coming; for all that are in the graves shall hear his voice, and shall come forth; they that have done good unto the resurrection of life, and they that have done evil to the resurrection of damnation." (1 Cor. xv. 20–24, and St. John v. 28, 29.)

Our blessed Lord having conversed familiarly with the eleven apostles for forty days after his resurrection, instructing them in the things pertaining to the kingdom of God; having extended their authority as his ministers, by giving them a commission to teach all nations, and make them his disciples, by baptizing them in the name of the Father, and of the Son, and of the Holy Ghost; and having promised them power from on high to enable them to discharge the duties of so laborious an office—conducted them as far as Bethany, that they might be witnesses to his ascension into heaven. (See St. Luke xxiv. 49–43, and Acts i. 6–12.)

That our blessed Lord ascended into heaven, will scarcely be denied in the present age by any one who admits that he rose from the dead. The ascension was indeed the natural consequence of the resurrection; for we cannot suppose that a man would be called back from the grave to live for ever in a world where all other men fall in succession a prey to death. The purpose for which he died was to recover for the descendants of Adam every privilege which they had forfeited through his transgression; and if, as has been generally believed, mankind were by the terms of the first covenant to enjoy eternal life in heaven, some proof was necessary that Christ by his death and resurrection had opened the kingdom of heaven to all faithful observers of the terms of the second. Hence it was prophesied (Psalm lxviii. 18; cx. 1; Micah ii. 13) of the Messiah, in whom all the nations of the earth were to be blessed, that "he should ascend on high, lead captivity captive, and sit on the right hand of God until his enemies should be made his footstool." It was therefore of the greatest importance to the apostles to have sufficient proof of their Master's exaltation to the right hand of the Majesty on high; for otherwise they could neither have looked for an entrance into heaven themselves, by a new and living way, as the author of the epistle to the Hebrews expresses it, nor have preached Jesus as the Messiah promised to their fathers, since they could not have known that in him these prophecies were fulfilled. But the proof vouchsafed them was the most complete that the nature of the thing would bear. The spectators of the ascension were many; for, according to the history of St. Luke, (Acts i. 12–16.) those who returned from the Mount of Olives to Jerusalem, and prepared themselves for the coming of the Holy Ghost, were in number about six score; and to such a cloud of witnesses the evangelist would not have appealed, had not the fact he was recording been very generally known. Yet these were perhaps but part of the witnesses; for since Christ had informed his disciples that he was to ascend to his Father and their Father, to his God and their God, and that he was going to prepare a place for them, that where he is there they might be likewise; we can hardly doubt but that all who believed in him as the Redeemer of the world would take care to be present, not only to view their Master's triumph over all his enemies, but also anticipate that glory which awaited themselves. It was probably on this occasion that he was seen after his resurrection by above five hundred brethren at once, of whom the greater part were alive at the writing of St. Paul's first epistle to the Corinthians.

But though such multitudes of people saw Jesus lifted up from the mount, till he gradually vanished out of their sight, some other evidence seemed necessary to certify them of the place to which he had ascended. Two angels therefore appear, and attest what human eyes could not see, but what was indeed the consequence of what they had seen. They attest that Christ had ascended to heaven, not to descend again till the last day; and surely, with respect to this point, the citizens of heaven were the most unexceptionable witnesses. We must therefore acknowledge and confess, against all the wild heresies of old, that Jesus Christ the Son of God, who died and rose again, did with the same body and soul with which he had lived upon earth ascend "into heaven, there to appear in the presence of God for us." (Heb. ix. 24.) Having in the outward tabernacle of this world once offered up himself a pure and perfect sacrifice for the expiation of our sins, he entered within the veil into the most holy place, there to present his blood before God himself, in order to obtain mercy for us, and restore us to the Divine favour. So that "if any man sin, we have an advocate with the Father, Jesus Christ the righteous, who is the propitiation for our sins, and not for ours only, but also for the sins of the whole world; and he is able to save to the uttermost those that come to God by him, seeing he ever liveth to make intercession for us." "Seeing then that we have a great high-priest, who is passed into the heavens, Jesus the Son of God, we may through him come boldly unto the throne of grace, that we may obtain mercy and find grace to help us in time of need."

But it is not the office a priest only that our Lord discharges in heaven; he is represented as sitting on the right hand of God, to denote that real authority with which he is now vested; "angels, and authorities, and powers, being made subject to him," (1 Peter iii. 22.) Hence it is, that after his resurrection, he said of himself, (Matt. xxviii. 18,) "all power is given unto me in heaven and in earth;" for, as St. Paul informs us, (Phil. ii. 8, 9, 10,) "because he humbled himself and became obedient unto death, even the death of the cross, therefore God hath highly exalted him, and given him a name which is above every name; that at the name of Jesus every knee should bow, of things in heaven, and things in earth, and things under the earth." And this submission is due to him, because "God raised him from the dead, and set him at his own right hand in the heavenly places, far above all principalities and powers, and might, and dominion, and every name that is named, not only in this world, but also in that which is to come; and hath put all things under his feet, and gave him to be head over all things to the church," (Eph. i. 20, &c.) As God, Christ possessed a kingdom, which, as it had not a beginning, can never have an end: but the dominion, of which the apostle is here treating, was conferred upon him as the mediator of the new covenant, and will no longer continue than till his enemies shall be subdued; for we are told that "he must reign till he hath put all enemies under his feet; and that the last enemy that shall be destroyed is death." "He will ransom his subjects from the power of the grave; he will redeem them from death. O death, he will be thy plague; O grave, he will be thy destruction," (Hosea xiii. 14.) The trumpet shall sound, the graves shall be opened, all the sons and daughters of Adam shall return to life, and death shall be swallowed up in victory. "Then cometh the end, when the office of mediator ceasing, he shall have delivered up the kingdom to God, even the Father, when he shall have put down all rule and all authority and power. For when all things shall be subdued unto him, then shall the Son also himself be subject unto him that put all things under him, that God may be all in all," (1 Cor. xv. 24–28.)

SECT. VII.—*Of Justification by Faith.*

Between *pardon* of sin and *justification* there is so close a connection, that many writers seem to consider the terms as synonymous, and to infer, that he who is pardoned is *ipso facto* justified. That every Christian, who shall be pardoned at the judgment of the great day, will likewise be justified, is indeed true; but in propriety of speech, *justification* is a word of very different import from *pardon*, and will entitle the Christian to what mere pardon could not lead him to expect. An innocent person, when falsely accused and acquitted, is *justified* but not *pardoned;* and a criminal may be *pardoned*, though he cannot be *justified* or declared innocent. A man whose sins are pardoned is freed from punishment; but the justified Christian is entitled to everlasting life, happiness, and glory. If we were only pardoned through Christ, we should indeed escape the pains of hell, but could have no claim to the enjoyments of heaven; for these, being more than the most perfect human virtue can merit, must be, what in the scriptures they are always said to be, "the gift of God through Jesus Christ our Lord." Hence it is that St. Paul, distinguishing, as we have done upon his authority, between mere remission of sins and justification of life, declares, (Romans iv. 25), that "Jesus our Lord was *delivered* for our *offences*, and *raised* again for our *justification*."

The word justification, in Scripture, has been very generally considered as a forensic term expressing the sentence of a judge. The most eminent reformed divines of all denominations, (Limborch, Bull, Waterland, Warburton, Beveridge, Vitringa, Gill, &c.) and even many of the Romanists themselves, have strenuously contended, that this is its genuine sense, when it is distinguished from mere remission of sins, regeneration, and sanctification; and if so, it will signify God's pronouncing a person *just*, either as being perfectly blameless, or as having fulfilled certain conditions required of him in the Christian covenant. But that "there is not a just man upon earth, who doth good and sinneth not," is made known to us by the most complete evidence possible, the joint dictates of our own consciences and of divine revelation; and therefore whosoever is pronounced just by the Judge of all the earth, must be so, either because, though not absolutely blameless, he has performed the conditions required of him in the covenant of grace, or because Christ has fulfilled all righteousness in his stead.

If this be the Scripture notion of justification, it must be the act of God, and cannot be the effect either of our faith or of our virtue. Accordingly, we are said by the apostle to be justified freely by his grace through the redemption that is in Jesus Christ; whom *God hath set forth* to be a propitiation through faith in his blood. (Rom. iii. 24, 25.) The act of justification therefore proceeds from the divine philanthropy, and cannot be performed by the instrumentality of faith; for it is not God, but man, who believes; and man is not the justifier of himself. To talk of any kind of *instrument* of justification besides the propitiation set forth by God, is indeed to make use of very improper language: "Omnis causa instrumentalis," says Bishop Bull, (Harmonia Apostolica, cap. ii. § 8.) "suo modo in effectum influit, eique effecti productio proprie attribui potest. Jam vero, cum justificatio nihil aliud sit quam gratiosus Dei actus, quo peccata nostra nobis condonet, ac nos ad salutem acceptet, valde absurdum esset dicere, vel fidem, vel opera nostra, vel quidvis áliud, nostri aut remittere peccata nostra, aut personas nostras acceptare: quod tamen, si instrumentalis causa justificationis fides sit, plane dicendum esset."

In this sentiment of the bishop of St. David's some of the most eminent divines both among the Calvinists and Arminians acquiesce. Many however have chosen to treat of justification not only in the active sense, as it is the act of God, for all admit that it is he who justifies; but likewise in a passive sense, as it means our *privilege* or *possession* held of him, when we are said to be justified by his grace. In this view of the subject they may speak with sufficient propriety, of an instrument of justification, not as the mean by which it is conveyed, but as the medium through which it is received by the true Christian. And hence it follows, that Waterland and Warburton strenuously maintain the doctrine of the Westminster Confession, "that faith receiving and resting on Christ is the alone instrument of justification; though it cannot be alone in the person justified, but must ever be accompanied with all other saving graces, and be a faith which worketh by love."

Obs. Notwithstanding this general agreement of Calvinists and Remonstrants on the subject of justification, there are several differences of sentiment, and still more of phraseology, when they descend to particulars. Of these an idea will be best formed by the perusal of the eminent writers on both sides.

"A notion (says Dr. Gill, Body of Divinity, vol. ii. book iii. chap. 8, sec. 5.) obtained some years ago, that a relaxation of the law and the severities of it has been obtained by Christ; and a new law, a remedial law, a law of milder terms, been introduced by him, which is the gospel; the terms of which are, faith, repentance, and new obedience; and though these be imperfect, yet being sincere, they are accepted by God in the room of perfect righteousness. But every article of this scheme is wrong; for the law is not relaxed, nor any of its severities abated; Christ came not to destroy, but to fulfil it; and therefore it requires the same holy, just, and good things, as ever. Nor is the gospel a new law. There is nothing in it which looks like a law; for it has no commands in it, but all promises, being a pure declaration of grace and salvation by Christ; nor are faith, repentance, and a new obedience, required by it as a condition of man's acceptance with God. Faith and repentance are gospel doctrines, and parts of the gospel ministry; they are graces, and not terms required to be performed by men of themselves. Faith is the gift of God, and repentance is a grant from him. It is not true that God will accept of an imperfect righteousness in the room of a perfect one; nor can anything more highly reflect upon the justice and truth of God, who is the judge of all the earth, than to suppose that he can ever account that as a righteousness which is not one."

Having thus proved by arguments which were almost in the same words stated long before by Bishop Beveridge, (see his Private Thoughts of Religion,) that the gospel is no relaxation of the law, he proceeds to lay down his own notions of justification, of which, he says, "the sole matter, or that for the sake of which a sinner is justified before God, is the righteousness of Christ —that which he did and suffered on earth, in our nature, in our stead, and as our representative. This is commonly called his active and passive obedience; and when the purity and holiness of his own nature was added to it, the whole made up the δικαιωμα του νομου, *the righteousness of the law*, which was fulfilled by him as the head and representative of his people, (Rom. viii. 4.); for whatever the law required is necessary to a sinner's justification before God, and it required of sinners more than it did of man in innocence. Man was created with a pure and holy nature, conformable to the pure and holy law of God; and it was incumbent on him to continue so, and to yield in it perfect and sinless obedience, in the failure whereof he was threatened with death. Man did fail, by which his nature was vitiated and corrupted, and his obedience became faulty and imperfect. He therefore became liable to the penalty of the law, and still perfect obedience was required of him. To the justification of a sinner, therefore, is required the most complete obedience, active and passive; or, in other words, purity of nature, perfect obedience, and the sufferings of death; all which meet in Christ, the representative of his people, in whom they are justified. There are, indeed, some divines who exclude the active obedience of Christ from being any part of the righteousness by which men are justified. They allow it to have been a condition requisite in him as a Mediator, qualifying him for his office; but deny that it is the matter of justification, or reckoned for righteousness to man. But without the active obedience of Christ the law would not be satisfied; the language of which is, *Do and live;* and unless its precepts be obeyed, as well as its penalty endured, it cannot be satisfied; and unless it be satisfied there can be no justification. If, therefore, men are justified by the righteousness of Christ, it must be by his active obedience imputed and made over to them, so as to become theirs, *even as David describeth the blessedness of the man unto whom God imputeth righteousness without works,* (Rom. iv. 6.) That this is really the way in which men are justified, Dr. Gill thinks evident, because they must be justified either by an inherent or by an imputed righteousness; but they cannot be justified by their own inherent righteousness, for that is imperfect, and therefore not justifying. Hence the apostle 'counts all things but dung, that he may win Christ and be found in him; not having his own righteousness, which is of the law, but that which is *through the faith of Christ*, the righteousness which is of *God by faith*,' (Phil. iii. 8, 9.) But by such a righteousness as this a man cannot be justified in any other way than by an imputation of it to him. Whence it follows, that '*as by one man's disobedience many were made sinners* by imputation, so *by the obedience of one shall many be made* righteous, by having that obedience placed to their own account.'"

As this author properly considers justification as the act of God, he does not approve of the language in which faith is called the instrument, either of conferring or receiving it. "Faith," says he, (Body of Divinity, vol. i. book ii. sec. 5,) "is merely the evidence of justification to the person justified; for 'faith is the evidence of things not seen.' The righteousness of God, of the God-man and Mediator Jesus Christ, is revealed from faith to faith in the everlasting gospel, (Rom. i. 17,) and therefore must be before it is revealed, and before the faith to which it is revealed. Faith is that grace whereby a soul, having seen its want of righteousness, beholds in the light of the Divine Spirit a complete righteousness in Christ, renounces its own, lays hold on that, puts it on as a garment, rejoices in it, and glories of it; the Spirit of God witnessing to his spirit that he is a justified person: and so he is evidently and declaratively 'justified in the name of the Lord Jesus, and by the Spirit of our God,' (1 Cor. vi. 11.) Faith adds nothing to the *esse*, only to the *bene esse* of justification; which is a complete act in the eternal mind of God, without the being or consideration of faith, or any foresight of it. In the account of God, a man is as much justified before his faith as after it; and after he does believe, his justification depends not on his acts of faith, for though *we believe not, yet God abides faithful* to his covenant-engagements with his son, by whose suretyship-righteousness the elect are justified; but by faith men have a comfortable sense, perception, and apprehension, of their justification, and enjoy that peace of soul which results from it. It is by that only, under the testimony of the Divine Spirit, that they know their interest in it, and can claim it, and so have the comfort of it."

Though this language differs from that of the Westminster Confession, the author seems not to teach a different doctrine; for if faith be that grace by which a soul renounces its own righteousness, and lays hold of Christ's, which it puts on as a garment, it must be that very thing which the compilers of the Confession meant by their definition of faith receiving and resting on Christ and his righteousness, when they called it "the alone instrument of justification." Accordingly this author elsewhere (Body of Practical Divinity, book i. chap. 6,) teaches, that "true faith in sensible sinners assents to Christ and embraces him, not merely as a Saviour of man in general, but as a special suitable Saviour for them in particular. It proceeds upon Christ's being revealed *in* them as well as *to* them, by the spirit of wisdom and revelation, in the knowledge of him as a Saviour that becomes them. It comes not merely through external teachings by the hearing of the word from men; for no man, saith our blessed Lord, can come to me except the Father draw him; but such souls as are thus drawn, having heard and learned of the Father, believe not only in the *doctrine* of Christ, but also in *himself*, trusting in him alone for everlasting life and salvation."

Were it not that Dr. Gill, in everything that he writes, has an eye to the doctrine of election and reprobation, which he carries to a greater height than almost any other divine with whose works we are acquainted, he would differ little in his notions of justification from the more moderate Arminians. "Justification," says Limborch, "is the merciful and gracious act of God, whereby he fully absolves from all guilt the truly penitent and believing soul, through, and for the sake of Christ apprehended by a true faith; or gratuitously remits sin upon the account of faith in Jesus Christ, and graciously imputes that faith for righteousness." Here, indeed, the imputation of Christ's righteousness is expressly denied; but Dr. Waterland, who can hardly be considered as a Calvinist, seems to contend for the imputation of that righteousness to the sinner, as well as for faith being the instrument by which it is received.

"It cannot be for nothing," says that able writer, (Summary View of Justification,) "that St. Paul so often and so emphatically speaks of man's being justified by faith, or through faith in Christ's blood; and that he particularly notes it of Abraham, that he *believed*, and that his faith was counted to him for justification, when he might as easily have said that Abraham, to whom the gospel was preached, was justified by gospel-faith and obedience, had he thought faith and obedience equally instruments of justification. Besides, it is on all hands allowed, that though St. Paul did not directly oppose faith to *evangelical works*, yet he comprehended the works of the *moral law* under those which he excluded from the office of *justifying*, in his sense of the word justification. He even used such arguments as extended to all kinds of works; for Abraham's works were excluded, though they were undoubtedly evangelical." To prove that he interprets the apostle's doctrine fairly, the author quotes, from the genuine epistle of Clemens of Rome, a passage, in which it appears, beyond a doubt, that this fellow-labourer of St. Paul so understood the doctrine of justifying faith as to oppose it even to evangelical works, however exalted. "It is true," continues Waterland, "Clemens elsewhere, and St. Paul almost everywhere, insists upon true holiness of heart and obedience of life as indispensable conditions of salvation or justification; and of that, one would think, there could be no question among men of any judgment or probity. But the question about conditions is very distinct from the other question about instruments; and therefore both parts may be true, viz., that faith and obedience are equally conditions, and equally indispensable where opportunities permit; and yet faith over and above is emphatically the instrument both of receiving and holding justification, or a title to salvation.

"To explain this matter more distinctly, let it be remembered, that God may be considered either as a party contracting with man on very gracious terms, or as a judge to pronounce sentence on him. Man can enter into the covenant, supposing him adult, only by assenting to it, and accepting it, to have and to hold it on such kind of tenure as God proposes; that is to say, upon a self-denying tenure, considering himself as a guilty man standing in need of pardon, and of borrowed merits, and at length resting upon mercy. So here, the previous question is, Whether a person shall consent to hold a privilege upon this submissive kind of tenure or not? Such assent or consent, if he comes into it, is the very thing which St. Paul and St. Clemens call *faith*. And this previous and general question is the question which both of them determine against any proud claimants who would hold by a more self-admiring tenure.

"Or if we next consider God as sittting in judgment, and man before the tribunal going to plead his cause, here the question is, What kind of plea shall a man resolve to trust his salvation upon? Shall he stand upon his innocence, and rest upon strict law? or shall he plead guilty, and rest in an act of grace? If he chooses the former, he is proud, and sure to be cast: if he chooses the latter, he is safe so far in throwing himself upon an act of grace. Now this question also, which St. Paul has decided, is previous to the question, What conditions even the act of grace itself finally insists upon? A question which St. James in particular, and the general tenure of the whole Scripture, has abundantly satisfied; and which could never have been made a question by any considerate or impartial Christian. None of our works are good enough to stand by themselves before Him who is of purer eyes than to behold iniquity. Christ only is pure enough for it at first hand, and they that are Christ's at second hand in and through him. Now because it is by faith that we thus interpose, as it were, Christ between God and us, in order to gain acceptance by him; therefore faith is emphatically the instrument whereby we receive the grant of justification. Obedience is equally a condition or qualification, but not an instrument, not being that act of the mind whereby we look up to God and Christ, and whereby we embrace the promises."

But though Dr. Waterland contends that faith is the instrument of justification, he does not, like the Antinomians, teach that it will save men without works. "The covenant of grace," says he, "has conditions annexed to it of great importance, for without them no instruments can avail. These are faith and obedience, as St. James hath particularly maintained. St. Paul had before determined the general and previous question respecting the plea by which we ought to abide; and when some libertines, as is probable, had perverted his doctrine of faith and grace, St. James showed that the very faith which rests in a covenant of grace, implies a cordial submission to the conditions of that covenant, otherwise it would be nothing but an empty ceremony. The perfect agreement between St. Paul and St. James in the article of *justification*, appears very clear and certain. St. Paul declares, that in order to come at justification, it is necessary to stand upon grace, not upon merit; which St. James does not deny, but rather confirms, in what he says of the perfect law of liberty, (James i. 25; ii. 12). St. Paul makes faith the instrument of receiving that grace; which St. James does not dispute, but approves by what he says of Abraham, (ii. 23); only he maintains, also, that in the conditionate sense, justification depends equally upon faith and good works; which St. Paul also teaches and inculcates in effect, or, in other words, through all his writings. If St. Paul had had precisely the same question before him which St. James happened to have, he would have decided the same as St. James did; and if St. James had had precisely the same question before him which St. Paul had, he would have determined just as St. Paul did. Their principles were exactly the same, but the questions were diverse; and they had different adversaries to deal with, and opposite extremes to encounter, which is a common case.

"It may be noted, that that faith which is here called a *condition*, is of much wider compass than that particular kind of faith which is precisely the instrument of justification. For faith as a condition means the whole complex of Christian belief, as expressed in the creeds; while faith as an instrument means only the laying hold on grace, and resting in Christ's merits, in opposition to our own deservings: though this also, if it is a vital and operative principle, (and if it is not, it is nothing worth), must of course draw after it an hearty submission to, and observance of, all the necessary conditions of that covenant of grace wherein we repose our whole trust and confidence; so that St. Paul might well say, "Do we then make void the law (the moral law) through faith? God forbid: yea, we establish the law," (Rom. iii. 51.) We exempt no man from religious duties, which are duties still, though they do not merit nor are practicable to such a degree as to be above the need of pardon: they are necessary conditions in their measure of justification, though not sufficient in themselves to justify, nor perfect enough to stand before God or to abide trial: therefore Christ's merits must be taken to supply their defects; and so our resting in Christ's atonement, by an humble self-denying faith, is our last resort, our anchor of salvation both sure and steadfast, after we have otherwise done our utmost towards the fulfilling of God's sacred laws, towards the performing of all the conditions required.

"That good works, internal and external, are according as opportunities offer and circumstances permit, *conditions* properly so called, is clear from the whole tenor of Scripture, as hath been often and abundantly proved by our own divines,[1] and is admitted by the most judicious among the foreign Reformed.[2] Yet some have been very scrupulous as to this innocent name, even while they allow the absolute necessity of good works as indispensable qualifications for future blessedness. Why not conditions therefore as well as qualifications? Perhaps because that name might appear to strike at absolute predestination, or unconditional election; and there may lie the scruple: otherwise the difference appears to lie rather in words than in things.

"Some will have them called not conditions, but *fruits* or *consequents* of justification. If they mean by justification the same as the grace of the Holy Spirit, and the first grace of faith springing from it, they say true; and then there is nothing more in it than an improper use of the word *justification*, except that from abuse of words very frequently arises some corruption of doctrine. If they mean only, that outward acts of righteousness are fruits of inward habits or dispositions, that also is undoubtedly true; but that is no reason why internal acts, virtues, graces, (good works of the mind), should not be called conditions of justification; or why the outward acts should not be justly thought conditions of preserving it. But if they mean that justification is ordinarily given to adults without any preparative or previous conditions of faith and repentance, that indeed is very new doctrine and dangerous, and opens a wide door to carnal security and to all ungodliness."

SECT. VIII.—*Of the Person and Work of the Holy Spirit.*

Our Saviour before his death promised to his disciples, that after his ascension to heaven he should send unto them another Comforter, (παρακλητος, *he who stands by one and assists as required, an advocate, a guide, a helper, &c.*) who should abide with them for ever, even the SPIRIT OF TRUTH, (John xiv. 16, 17, &c.) Elsewhere this Spirit is denominated "the Holy Spirit," "the Spirit of God," "the Spirit of Christ," &c., and is frequently mentioned in union with the Father and the Son as the object of adoration and the author of blessing. (Comp. Matt. xxviii. 19; 2 Cor. xiii. 14, &c.) Hence theologians have denominated the Spirit the third person in the divine Trinity. That there are three persons in the one Godhead, has been shewn at large in a former section of this article; and that the Holy Ghost is one of these three, might be safely concluded from the passages just referred to. But as more plausible objections have been urged against his divinity than any that we have met with against the divinity of Christ, it may not be improper to consider these before we proceed to give an account of the graces which he imparts to the church. By the Arians the Holy Ghost is considered as a creature; by the Socinians and modern Unitarians, as they call themselves, the words *Holy Ghost* are supposed to express, not a person or spiritual subsistence, but merely an energy or operation, a quality or power, of the Father, whom alone they acknowledge to be God. If this doctrine can be confuted, the Arian hypothesis will fall to the ground of itself; for it is not conceivable that any inspired teacher should command his followers to be baptized in the name of the self-existent God and two creatures.

[2] Vossius de Bonis Operibus, Thes. x. p. 370. Op. tom. vi. Frid Spanhem. fil. Op. tom. iii. p. 141, 159.

It is admitted by the Socinians themselves, that in the scriptures many things are spoken of the Holy Ghost which can be properly predicated only of a person; but the inference drawn from this concession they endeavour to invalidate by observing, that in scripture there are likewise expressions in which things are predicated of abstract virtues, which can be literally true only of such persons as practise those virtues. Thus when St. Paul says, (1 Cor. xiii. 4–8), that "charity suffereth long and is kind, charity envieth not, charity vaunteth not itself, is not puffed up," &c., we cannot suppose his meaning to be, that these actions are performed by charity in the abstract, but that every charitable person, in consequence of that one Christian grace, suffereth long and is kind, envieth not, vaunteth not himself, and is not puffed up, &c. In like manner, say they, personal actions are attributed to the Holy Ghost, which itself is no person, but only the virtue, power, or efficacy, of God the Father; because God the Father, who is a person, performs such actions by that power, virtue, or efficacy, in himself, which is denominated the Holy Ghost. Thus when we read (Acts x. 19, 20), that "the Spirit said unto Peter, Behold three men seek thee; arise therefore and get thee down, and go with them, doubting nothing, for I have sent them;" we must understand that God the Father was the person who spoke these words and sent the three men; but because he did so by that virtue in him which is called the *Spirit*, therefore the *Spirit* is said to have spoken the words and sent the men. Again, when "the Holy Ghost said (Acts xiii. 2) to those at Antioch, Separate me Barnabas and Saul for the work whereunto I have called them;" we are to conceive that it was God the Father who commanded the two apostles to be separated for the work to which he had called them; but because he had done all this by that power within him which is called the Holy Ghost, therefore his words and actions are attributed to the Holy Ghost, just as long-suffering in men is attributed to charity.

This reasoning has a plausible appearance, and would be of much force were *all* the actions which in scripture are attributed to the Holy Ghost of such a nature that they could be supposed to have proceeded from the person of God the Father in consequence of any particular power or virtue in him; but this is far from being the case. Thus, the Spirit is said (Rom. viii. 26, 27) to make intercession for us; but with whom can we suppose God the Father, the fountain of divinity, to intercede? Our Saviour assured his disciples, (John xiv. 26; xv. 26; xvi. 13, 14, 15), that the Father would, in his name, send to them the Holy Ghost, who is the Comforter; that he would himself send the Comforter unto them from the Father; that the Comforter should not speak of himself, but speak only what he should hear; and that he should receive of Christ's, and shew it unto them. But we cannot, without blasphemy and absurdity, suppose that the Father would, in the name of Christ, send himself; that the Son would send the Father from the Father; and the Father would not speak of himself, but speak only what he heard; or that either the Father in person, or a quality of the Father, should receive any thing of Christ to shew unto the apostles.

The sagacity of Socinus perceived the force of such objections as these to his notion of the Holy Ghost being nothing more than the power of the Father personified; and therefore he invented another *prosopopœia* to serve his purpose in the interpretation of those texts to which this one cannot be applied. "The Spirit of God," says he, (Faust. Socinus in Resp. ad Wiekam, cap. 10), "may be considered either as a property or power in God, or as the things on which that power is working. When taken in the former sense, the Spirit, where any personal attribute is given to it, means God the Father; when taken in the latter sense, it means the man on whom the power of the Father is working; who, as long as he is affected by that power, is therefore called the Spirit of God;" and he quotes, we think most absurdly, the tenth verse of the second chapter of the first epistle to the Corinthians, as a text in which by the Spirit is meant an inspired man who could search all things, yea, even the deep things of God.

How his modern followers, who deny the plenary inspiration even of Christ, will relish such a degree of inspiration as this, which raises mere men to a temporary equality with God, we know not; but leaving them to settle the dispute with their master, we shall produce one or two passages in which personal attributes are given to the Spirit of God, when it is impossible to conceive that Spirit, either as a power inherent in the Divine Father, or as the person on whom that power is operating. We need not bring new texts into view, as some of those already quoted will serve our purpose. When our Saviour promises that the Holy Ghost, the Comforter, the Spirit of truth, should be sent by the Father and the Son to the apostles, we have seen, that by this Spirit he could not mean the Father or a property of the Father; neither could he possibly mean the apostles themselves, unless we are to suppose that the Father and the Son sent St. Peter to St. Peter, and that St. Peter, so sent, came to St. Peter. Again, when Christ says of the Holy Ghost, "he shall receive of mine, and shall shew it unto you," he could not, for the reason already assigned, mean by the Holy Ghost the Father or the power of the Father; and surely his meaning was not, that the apostles, under the influence of the power of the Father, should receive something and shew it each to himself. The Holy Ghost therefore is unquestionably a person; for though there are many passages of scripture in which the *gifts* of the Holy Ghost are called the *Holy Ghost*, they are so called by a very common figure of speech, in which the effect receives the name of its cause: and since this person is joined with the Father and the Son in the formula of Christian baptism; since they who lied to the Holy Ghost are said (Acts v. 4) to have lied unto God; since blasphemy against him is a more heinous offence than the same sin against even the Father or the Son, (Mark iii. 28, 29); and since it was by the operation of the Holy Ghost that Jesus Christ was conceived of the Virgin Mary, and even on that account called the Son of God (Luke i. 35); it follows that the Holy Ghost is God, of the same substance with the Father and Son.

It was this Divine Spirit which, on the day of Pentecost, inspired the apostles with the knowledge of different languages; and as these were given only to enable them to preach the gospel to every creature, it can admit of no doubt but that He, who so amply provided the means of preaching, would take care that the gospel should be preached in purity. Our Saviour had told his apostles, that the Comforter would guide them into all the truth, (ἐις πασαν την ἀληθειαν), and bring all things to their remembrance, whatsoever he had said unto them; but if they had not comprehended the meaning of what he said, the bare remembrance of his sayings would have been of little importance. That before this miraculous shedding abroad of the Spirit they had but a very imperfect knowledge of his doctrines, and of the purpose for which he had come into the world, is apparent from that unseasonable question which they put to him when assembled to witness his glorious ascension; "Lord, wilt thou at this time restore again the kingdom to Israel?" Their minds still cherished with fondness the vain prospect of temporal power; but after the day of Pentecost they were directed to nobler objects. From the same Spirit they received diversities of gifts besides that of language, and thus were well qualified to declare to the world the whole counsel of God.

But the work of the Holy Spirit has not been restricted to the apostles and other possessors of miraculous gifts in the early church. As man is designed for a supernatural state in heaven, he stands in need of supernatural direction to guide him to that state. "No man," says our Saviour, "can come to me except the Father draw him;" and the apostle tells us, that "as no man knoweth the things of a man save the spirit of a man which is in him, even so none knoweth the things of God but the Spirit of God," (John vi. 44; 2 Cor. ii. 11.) This omniscient Spirit indeed searcheth all things, yea even the "deep things of God," and revealeth them to the sons of men, to enlighten their understandings and purify their hearts. The grace which he sheds abroad is either external and general, or internal and particular. The former has been extended to the whole church of God under the patriarchal, Mosaic, and Christian dispensations, in such a revelation of the divine will as was sufficient to instruct men unto eternal life, whether they had a full view or not of that stupendous plan of redemption, by which the kingdom of heaven was opened to them after the forfeiture of the terrestrial Paradise; for there have been "holy prophets ever since the world began; and prophecy came not at any time by the will of man, but holy men of God spake as they were moved by the Holy Ghost," (Luke i. 70, and 2 Peter i. 21.) Hence it is that all scripture was given by inspiration of God to teach every thing which it is necessary for us to know and believe; and the scripture is that work of the Spirit which is extended to the universal church.

But the same spirit which thus generally reveals the object of faith to the church, does likewise particularly illuminate the minds of individual believers, working in them an assent to that which is taught them from the written word. It was thus that "the Lord opened the heart of Lydia, (Acts xvi 14,) that she attended to the things which were spoken by Paul;" it is thus that "the word preached doth not profit if it be not mixed with faith in them who hear it," (Heb. iv. 2); and it is thus that "God deals to every man the measure of faith," (Rom. xii. 3); for "by grace are we saved through faith, which is not of ourselves; it is the gift of God," (Eph. ii. 8.) This illumination of the Spirit was conveyed to the apostles "in a sound from heaven as of a rushing mighty wind," because it was meant to testify to the world that they were chosen ministers of the gospel; but the ordinary Christian receives it "in the still small voice," because it is conveyed to him only to "open his understanding that he may understand the scriptures."

Another operation of the Spirit on the minds of believers is that which in scripture is called Regeneration; for "according to his mercy God saveth us by the washing of regeneration and renewing of the Holy Ghost, which he sheds on us abundantly through Jesus Christ our Lord," (Tit. i. 5, 6.) To those who believe that we derive from Adam a corrupted nature, this particular grace must appear so absolutely necessary, that without it we could have no relish for heaven or heavenly things. "The natural man," we are told, "receiveth not the things of the Spirit of God, for they are foolishness to him; neither can he know them, because they are spiritually discerned," (1 Cor. ii. 14.) Indeed whatever be the powers of our moral faculties, when compared with those of our first father, it is so long before they be completely developed, that we should infallibly be lost, if we were not blessed by a supernatural guide, when reason is incapable of directing our conduct. Our passions and appetites are in their full strength before experience has furnished the mind with materials, by means of which motives may be weighed; and therefore it would be impossible, without the aid of a divine interference, completely to overcome those evil habits which are formed by sinful indulgence. So true is it, that "except a man be born again of water and of the Holy Ghost, he cannot enter into the kingdom of God." This change in our dispositions, from an immoderate attachment to earth to a relish for the things of heaven, is in scripture called "a renewing of our minds, a new creation, a new man;" in opposition to our natural disposition, which is called "the old man, corrupted according to the deceitful lusts."

A third office of the Holy Spirit is to *lead*, *direct*, and *govern* us through all the periods of our lives. Without such a leader and guide, the temptations with which we are surrounded would certainly overcome us, and we should faint long before we arrive at the end of our journey. By the very constitution of our nature we are subjected in some degree to the influence of sense, of which the objects are present, while the enjoyments of heaven are future, and seen, as at a distance, only by the eye of faith; but "the law of the Spirit of life, in Christ Jesus, hath made us free from the law of sin and death;" for God worketh in us both to will and to do of his good pleasure; and as many as are thus led by the Spirit of God, they are the sons of God; and while they walk in the Spirit, they do not fulfil the lusts of the flesh." Without the aid of the same Spirit, we could not even make our prayers acceptable; for since "our confidence in God is, that he heareth us only when we ask any thing according to his will; and since we know not what we should pray for as we ought, the Spirit itself maketh intercession for us with groanings which cannot be uttered." (Rom. viii. 26.)

A fourth operation of the Holy Ghost, as he is the sanctifier of Christians, is to join them to Christ, and make them members of that one body of which he is the head. "For by one Spirit are we all baptized into one body, (1 Cor. xii. 12, 13); and as the body is one and hath many members, and all the members of that one body being many are one body, so also is Christ." "Hereby we know that God abideth in us, by the Spirit which he hath given us."

It is likewise the office of the Holy Ghost to give us an earnest of our everlasting inheritance, to create in us a sense of the paternal love of God, and thereby to assure us of the adoption of sons. "As many as are led by the Spirit of God, they are the sons of God; and because we are sons, God hath sent forth the spirit of his Son into our hearts. For we have not received the spirit of bondage again to fear; but we have received the Spirit of adoption, whereby we cry Abba, Father; the Spirit itself bearing witness with our spirit, that we are the children of God." (Gal. iv. 6; Rom. viii. 15, 16.)

By these, and the like means, does the Spirit of God sanctify the sons of men; and in consequence of this sanctification proceeding immediately from his office, he is called the Holy Spirit and the Comforter. This is such a provision "for renewing us in the spirit of our minds, and enabling us to put on the new man, which, after God, is created in righteousness and true holiness," as, when made known by revelation, appears to have been expedient, may be conceived to have been even necessary, and though reason could hardly have hoped for it, is contradicted by none of our natural notions either of God or of man.

Smith On the Personality of the Holy Spirit. Lond. 1831. Wardlaw's Discourses on the Socinian Controversy, Disc. x.

SECT IX.—*Of Death and its consequences.*

As death has been introduced into our world by sin, and as every member of the race has sinned, the lives of all are forfeited and must in due time be yielded as Providence may appoint. When this takes place, the soul is separated from the body, and the latter speedily decomposes into kindred dust. The former, however, still retains possession of all its peculiar faculties, and passes at once into a state of separate existence, the character of which is determined by the conduct of the individual during life. To those who have availed themselves of the gracious provision made by Christ for their redemption, death brings an immediate entrance into the enjoyment of heaven; while for those who have neglected or despised that provision, there remains only the endurance of the punishment which the Great Judge of all shall see necessary to inflict. (Comp. Rom. v. 12; Matt. x. 28; Luke xvi. 22—31; Phil. i. 23; Rom. xiv. 13, &c.)

This state of separate existence is destined to continue only for a time. Christ has himself arisen from the dead as "the first fruits of them that sleep," and we are assured, that as he arose, so must all the dead who possess that nature of which he partook, be raised at the last day. When that period arrives, the Saviour shall again, in person, revisit this world, summon from their grave the bodies of all mankind who have died, change in a moment the bodies of those who shall then be alive, and afterwards proceed to a solemn trial of the whole, each one by himself, according to their deeds done in the body. At the close, the eternal destiny of each will be announced, and the mediatorial reign of Christ terminated by the introduction of the righteous into the fulness of that celestial enjoyment to which our race was originally destined, and the banishment of the wicked into that place which was prepared for the devil and his angels. (Comp. 1 Cor. xv.; John xi. 23–26; Matt. xxv. 31–46; Rom. xiv. 9, 10; 2 Thess. i. 5–10, &c.)

Such are the leading principles of that great system of religious truth which the Bible unfolds. In stating them, our object has uniformly been, with regard to such as are generally adopted among pious inquirers, to present them clearly, and with their Scripture evidence, to our readers; and in regard to those on which differences of opinion have prevailed among such, to bring forward, candidly and impartially, the views held, and the reasons urged, on both sides. It is for the intelligent reader, with his Bible in his hand, to determine for himself what is right; and, as one who must answer to the Judge of all for his opinions as well as his conduct, to embrace and follow what he is satisfied the inspired writers teach.

THEOPHRASTUS, a celebrated philosopher, was a native of Eresium, a maritime town in the island of Lesbos, and is supposed to have been born about the year 392 before the Christian era. His father was by trade a fuller. The original name of the son, we are informed, was Tyrtamus; but on account of his conspicuous eloquence, he was called Euphrastus, and afterwards Theophrastus. At an early age he repaired to Athens, where he successively became the disciple of Plato and of Aristotle. On the retirement of the latter, he became the head of the Peripatetic school; and so high was his reputation as a teacher of philosophy, that at one period the number of his scholars amounted to two thousand. He appears to have reached a very advanced age. If the preface to his Characters is genuine, and if one passage which it contains is correct in the reading, he undertook that work at the age of ninety-nine. This statement however cannot be received without the utmost suspicion. He succeeded Aristotle in 322, and was himself succeeded by Strato in 287 B.C. He had thus presided in the Lycæum for about thirty-five years.[1] His works, according to the catalogue of Diogenes Laertius, were very numerous; and several of them have been preserved in a state more or less perfect. To the stock of natural knowledge he made some important contributions. The largest of his works are two which relate to the history and to the causes of plants; and by these he has established a claim to be regarded as the father of botanical science. His Characters form one of the most remarkable compositions which ancient Greece has bequeathed to our times.

The works of Theophrastus were first printed by Aldus, in two volumes of his edition of Aristotle, Venet. 1497–8, fol. A separate edition was long afterwards produced by Heinsius, Lugd. Bat. 1613, fol. This only contains the text, and a Latin version, without annotations; nor does the very learned editor appear to have bestowed any extraordinary labour on the undertaking. A more elaborate edition was at length published by Schneider, Lipsiae, 1818–21, 5 tom. 8vo. The text is comprised in the first volume; the others are occupied with a Latin version, annotations, various readings, and an index. Of the "Historia Plantarum" an elaborate edition was published by Bodæus, Amst. 1644, fol. A separate volume had formerly appeared under the title of "Julii Cæsaris Scaligeri Animadversiones in Historias Theophrasti." Lugduni, 1584, 8vo. The same learned man had likewise published "Commentarii et Animadversiones in sex libros de Causis Plantarum Theophrasti." Lugd. 1566, fol. The octavo volume is a book of rare occurrence. An English translation of the treatise on stones, accompanying the original, was published by Sir John Hill, M.D. Lond. 1746, 8vo.

Of the Characters of Theophrastus, the separate editions are very numerous. The earliest, which only includes fifteen characters, is that of Pirckheymher, Norembergae, 1527, 8vo. But for the most able and conspicuous edition we are indebted to Casaubon, Lugd. 1592, 8vo. This edition, which has often been reprinted, is accompanied with a most learned and elaborate commentary. Here we ought not perhaps to overlook the edition of Needham, Cantab. 1712, 8vo. He has published the prelections of Duport, professor of Greek at Cambridge, on thirteen of the characters, and has reprinted the commentary of Casaubon. The editions by Fischer in 1763, and Schneider in 1799, likewise deserve to be specified. The number of characters Casaubon had augmented to twenty-eight. Other two were long afterwards brought to light by Amaduzzi, who published them in a splendid volume printed by Bodoni: "Characterum Ethicorum Theophrasti Eresii Capita duo hactenus anecdota, quæ ex cod. MS. Vaticano saeculi XI. Græce edidit, Latine vertit, præfatione et adnotationibus illustravit Johannes Christophorus Amadutius." Parmæ, 1786, 4to. Here the Greek text occupies six pages, but the volume extends to nearly one hundred and forty. The Characters of Theophrastus have been translated into many languages. The version of La Bruyere, with additional characters by the translator, ranks among the most conspicuous books in the French language. His version was transferred into English in 1699: Budgell's translation of the original followed in 1713, and Gally's in 1725. A more recent version has appeared under the subsequent title: "The Characters of Theophrastus, translated from the Greek, and illustrated by physiognomical sketches. To which are subjoined the Greek text, with notes, and hints on the individual varieties of human nature. By Francis Howell." Lond. 1824, 8vo.

---

[1] Clinton's Fasti Hellenici, vol. ii. p. 183.

THEOPOMPUS, a celebrated Greek orator and historian, was born in the island Chios, and flourished in the reign of Alexander the Great. He was one of the most famous of all the disciples of Isocrates, and won the prize from all the panegyrists whom Artemisia invited to praise Mausolus. He wrote several works, which are lost.

THEORBO (Ital. *Tiarbo*), a large kind of lute, long disused.

THEOREM, a proposition which terminates in theory, and which considers the properties of things already made or done; or it is a speculative proposition deduced from comparing together several definitions. A theorem is something to be proved, and a problem something to be done.

THEORY, in general, denotes any doctrine which terminates in speculation, without considering the practical uses or application thereof.

THEOSOPHISTS, a sect of men who pretend to derive all their knowledge from divine illumination. They boast that, by means of this celestial light, they are not only admitted to the intimate knowledge of God, and of all divine truth, but have access to the most sublime secrets of nature. They ascribe it to the singular manifestation of divine benevolence, that they are able to make such a use of the element of fire, in the chemical art, as enables them to discover the essential principles of bodies, and to disclose stupendous mysteries in the physical world. They even pretend to an acquaintance with those celestial beings which form the medium of intercourse between God and man, and to a power of obtaining from them, by the aid of magic, astrology, and other similar arts, various kinds of information and assistance. To this class belonged Paracelsus, Robert Fludd, Jacob Böhm or Bœhmen, Van Helmont, Peter Poiret, and the Rosicrucians.

THERAPEUTÆ, a term applied to those that are wholly in the service of religion. This general term has been applied to particular sects of men, concerning whom there have been great disputes among the learned.

THERAPEUTICS, that part of medicine which acquaints us with the rules that are to be observed, and the medicines to be employed, in the cure of diseases.

THERMÆ, hot baths or bagnios. Luxury and extravagance were in nothing carried to such heights as in the thermæ of the Roman emperors. Ammianus Marcellinus complains that they were built to such an extent as to equal whole provinces; from which description Valesius would make an abatement, by reading *piscinæ* instead of *provinciæ*. And yet after all, the remains of some still standing are sufficient testimonies for the historian's censure; and the accounts transmitted of their ornaments and furniture, such as being laid with precious stones (Seneca), set round with seats of solid silver (Pliny), with pipes and cisterns of the same metal (Statius), rather confirm than invalidate the censure. The most remarkable bagnios were those of Diocletian and Caracalla at Rome, great part of which remains at this day. The lofty arches, stately pillars, variety of foreign marble, curious vaulting of the roofs, great number of spacious apartments, all attract the curiosity of the traveller. They had also their summer and winter baths.

THERMIA, an island of Greece, in the southern part of the Archipelago. It is about fifty-five square miles in extent, is flat on the coast, but increases in height towards the centre. The soil is generally fertile, and produces good wheat, wine, figs, and cotton wool. The raising of silk is an important object of pursuit; and much honey and wax are collected. It contains 6000 inhabitants, all Greeks. It formerly had natural warm baths, but they are not now in use. The chief town is of the same name, and stands on the north-east side of the island. It is the seat of a Greek bishop, who has sixteen churches under his jurisdiction. Near to it there is a very secure harbour, called Porto S. Grini, where one half of the population reside. Long. 24. 15. E. Lat. 37. 20. N.

Inventi of the momete

THERMOMETER, from θερμὸς, *warm*, and μετρέω, *I measure;* an instrument for indicating the temperature of bodies, or the intensity of their heat or cold, in terms of the expansion of one or more of them. But such an instrument is seldom adapted to afford any direct measure of absolute heat; for the expansion of every substance which has yet been properly tried, proceeds in some higher ratio than the corresponding increase of absolute heat. Of this, air affords a remarkable example, as will be seen in the sequel. Thermometers seem to have been invented about the end of the sixteenth or beginning of the seventeenth century, though, like many other useful inventions, it is not agreed to whom the honour of the first of them belongs. Boerhaave ascribes it to Cornelius Drebel, Fulgenzio to Paolo Sarpi, and Sanctorio claims this honour for himself, being supported by Borelli and Malpighi. But M. Libri, after bestowing a great deal of labour and research on the subject (*Annales de Chimie* for December 1830), maintains, principally on the authority of Castelli and Viviani, that Galileo had invented the thermometer prior to 1597, and that Sagredo perfected it. There is nothing improbable however in thermometers having been really invented by several different persons, independently of each other, and much about the same time.

Air-t momet

Plate CCCCX

The first form of an instrument for indicating the temperature, seems to have been a very imperfect air-thermometer. It had been long known that air expands considerably with heat, and contracts again with cold, and that this expansion or contraction is greater or less according as the heat or cold applied is so. The principle, then, on which this air-thermometer was constructed is very simple. It consists of a glass tube, BE, fig. 1, Plate CCCCXCIV., connected at one end with a large glass ball A, and having its other end immersed in an open vessel, or terminating in a ball DE, with a narrow orifice at D; which vessel or ball contains some coloured liquor that will not easily freeze. But the ball A must be first warmed, to expel a portion of the air through the orifice D; and then, while cooling again, the liquor, pressed by the atmosphere, will enter the ball DE. The quantity of included air is to be so adjusted that, at a mean temperature of the weather, the liquor may stand near the middle of the tube, as at C, when the weight of the liquor, and the elasticity of the included air, counterbalance the pressure of the atmosphere. As the temperature increases, the included air, expanding thereby, will drive the liquor into the lower ball, and consequently its surface will descend in the tube. On the contrary, as the temperature falls, the air in the ball contracts, and the liquor pressed by the atmosphere will ascend; and such ascent or descent will be more or less, according to the change of temperature. To the tube is affixed a graduated scale, by means of which the motions of the liquor in the tube, and consequently the variations in the temperature, may be observed.

Its defe

Alcoh therm ter.

This instrument having been found extremely defective, owing to the air in the tube being affected by every variation in the pressure of the atmosphere, the Florentine Academy, about the middle of the seventeenth century, instead of air, employed alcohol, which, being coloured, was enclosed in a fine glass tube, having a hollow ball at one end A, fig. 2, and closed at the other end D. The ball and tube were filled with alcohol, so as to stand at a convenient height, as at C, when the weather is of a mean temperature. This may be effected by immersing the open end of the tube into a vessel of coloured alcohol, and then heating the ball to expel the greater part of the air, or by placing it under a receiver of the air-pump. When the thermometer is properly filled, the end D is closed by drawing it to a point, and slightly melting it at a lamp, and it is then said to be hermetically sealed. Formerly the included air was generally left of about one third its natural density, to prevent the alcohol in the tube from separating; but some now try to expel the air entirely, and assign the same reason for so doing. When the temperature increases, the alcohol expands, and rises in the tube; and when the heat decreases, it descends, as measured by means of an attached scale.

The alcohol thermometer, being unaffected by variations in the pressure of the atmosphere, soon came into general use, and was at an early period introduced into Britain by Mr Boyle. To this instrument, as then used, there are, however, many objections. The liquor employed not being always of the same strength, different tubes filled with it, and exposed to the same temperature, did not correspond. It was another defect, that the scale did not commence at any fixed point. The highest term was adjusted to the great sunshine heats of Florence, which are very variable and undetermined; and frequently the workman formed the scale after his own fancy. While the thermometer was so defective, it could not be of general use.

To discover some fixed point by which a determinate scale might be obtained, to which all thermometers might be accurately adjusted and rendered comparable among themselves, was the next desideratum. Mr Boyle, who had at an early period studied the subject, proposed the freezing point of oil of aniseeds; but this he soon abandoned. Dr Halley next proposed that thermometers should be graduated in a deep pit, where the temperature in all seasons is pretty uniform; and that the point at which the spirit of wine stood there, should be the commencement of the scale. But this was evidently so inconvenient that it also was speedily abandoned. The freezing point of water he regarded as a variable one.

It seems to have been reserved for the genius of Sir Isaac Newton to determine this important point, on which the accuracy and value of the thermometer depends. He chose, as fixed, those points at which water freezes and boils; the very points which experiments have since determined to be the most fixed and convenient. Sensible of the disadvantages of spirit of wine, he tried linseed oil, which is capable of about fifteen times greater expansion. It has not been observed to freeze even in great colds, and it bears a considerable heat before it boils. With these advantages, it was, in 1701, used by Newton, who estimated by it the temperatures of boiling water, melting wax, boiling spirit of wine, and melting tin. His method of adjusting the scale was this. Supposing the bulb, when immersed in thawing snow, to contain 10,000 parts, he found the oil expand by the heat of the human body so as to take up $\frac{1}{39}$th more space, or 10,256 such parts; and by water boiling strongly 10,725, and by melting tin 11,516: so that, reckoning the freezing point as a common limit between heat and cold, he there began his scale, marking it 0°, and the heat of the human body he made 12°; and assuming the degrees of heat proportional to the expansion, or 256 : 725 : : 12 : 34, this last will express the heat of boiling water, and, by the same rule, 72 that of melting tin.

To the application of linseed oil as a measure of heat and cold, there are insuperable objections. It is so viscid, and adheres so strongly to the sides of the tube, that it moves too slowly. In a sudden cold, so much remains adhering to the sides of the tube, that the top of the oil is seen lower than the temperature requires it.

All the thermometers hitherto proposed having been liable to many inconveniences, this led Reaumur to attempt a new one, which was described in the *Mémoires de l'Académie* for 1730. This thermometer was made with spirit of wine. He took a large ball and tube, graduating the latter such, that the space from one division to another might contain the 1000th part of the liquor as it stood at the freezing point, which he adjusted by an artificial congelation of water. Then putting the ball and part of the tube into boiling water, he observed whether it rose eighty divisions; if it exceeded these, he added water, or if it fell short of eighty divisions, he added rectified spirit. The liquor thus prepared served for making a thermometer of any size which would agree with his standard.

Reaumur's spirit of wine thermometer.

But as the bulbs were three or four inches in diameter, the surrounding ice would be melted before its temperature could be communicated to the whole bulb, and consequently the freezing point would be marked too high. Dr Martine accordingly found, that instead of 32° Fahrenheit, it corresponded with 34°, or a little above it. Doubts have often been started whether Reaumur had really ever put his thermometer in boiling water, considering that alcohol boils at a much lower temperature. But unless the upper end of the tube be open, or comparatively cold, the alcohol so enclosed will, owing to the increased pressure, scarcely boil at all, and more especially if a portion of air be included along with it. No doubt there will be some risk of bursting the bulb, though not much with such weak alcohol as Reaumur's. It is however quite obvious that the boiling point of any liquid with which a thermometer may be filled is not necessarily the upper limit of its scale.

Its defects.

At length mercury was proposed as a fluid preferable to any yet employed in the construction of thermometers. The first idea of this is usually ascribed to Dr Halley; but he did not put it in practice, on account of the small expansibility of mercury. Boerhaave says the mercurial thermometer was first constructed by Olaus Roemer; but the honour of this is generally given to Fahrenheit of Amsterdam, who described it to the Royal Society of London in 1724.

Mercurial thermometers.

Mercury is superior to alcohol and oil, except for very low temperatures, and is much more manageable than air. Of all liquids it is the most easily freed from air. It sustains a heat of 680° of Fahrenheit's scale, and does not congeal till it fall 39 or 40 degrees below 0°. It is the most sensible of any fluid to heat and cold, even air not excepted. Count Rumford found that mercury was heated from the freezing to the boiling point of water in 58 seconds, while water took 133 and air 617 seconds. The expansion of mercury is only about $\frac{1}{6}$th of that of alcohol, but it is sufficient for most of the purposes of a thermometer. As to what is usually esteemed the chief thermometric property of mercury, that of its variations of volume being nearly proportional to the variations in its absolute heat; this at best only argues the mercurial thermometer to be a tolerably good measure of the variations of its own heat, or of that of any other mass of mercury, which certainly is a property of very limited importance, if, after all, it leave us in the dark regarding the relation which subsists between the degrees of the mercurial scale and the corresponding variations of the absolute heat in other bodies.

Perhaps the simplest mode of filling a mercurial thermometer is to put the mercury into a paper funnel tied round the top of the tube. But unless the bore be unusually large, no mercury will enter it till the air be more or less expelled by heating the bulb; and then, on allowing it to cool again, the atmospheric pressure will force in the mercury. This operation should be done cautiously, by alternately heating gently and then cooling the bulb, and at length making it boil so as completely to expel the air. It is almost needless to add, that the tube as well as the mercury should be perfectly clean. To close the extremity of the tube, it is first softened by heat and drawn to a capillary orifice. Then, if it is wished to free the tube entirely of air, the bulb is heated fully to the highest temperature it is ever intended to measure, and whilst in that state, the mercury then filling the whole tube, the capillary point is to be melted in the flame of a lamp.

To render a very slender thread of mercury more distinctly visible, Dr Wilson of Glasgow introduced tubes with flattened bores. This form, which is now in very general use, has often been objected to, as tending to render the bore unequal; but from attentively witnessing the process of drawing tubes, we are rather at a loss to see any ground for the objection. The uniformity of a bore may be easily tested by trying whether the same minute quantity of mercury occupies the same length in every part of the tube when shifted through it. There is however one fortunate circumstance regarding tubes, which seems to be entirely overlooked, namely, that the bore, whether cylindrical or flattened, is seen considerably magnified by the refraction of the glass.

The bulbs of thermometers are generally spherical. Sometimes, however, to suit particular purposes, or to acquire more speedily the temperature of contiguous bodies, other figures are given them, such as that of a pear, an egg, a lens, or a cylinder. When a bulb is exposed to any pressure materially different from the mean of the atmosphere, its size, especially if large and thin in the glass, is so much affected as sensibly to alter the height of the mercury in the stem; but this is so different in different thermometers, that the requisite correction can only be ascertained for any one by actual trial.

Fixed points.

The fixed points which are now universally adopted for thermometers are the boiling and freezing points of water. The boiling water point, it is well known, varies some degrees according to the pressure of the atmosphere. In an exhausted receiver water boils at 98° or 100° Fahrenheit, whereas in Papin's digester it may require 400°. Nay, unless the bottom of the digester be hotter than the top, the pressure of the steam will completely prevent any boiling till the vessel burst. Hence it appears that water boils at a lower point, according to its height in the atmosphere, or to the smaller pressure of the air upon it.

The history, as well as the mode of applying the variations in the boiling point of water to the mensuration of heights, has been given by Sir John Leslie under the article Barometrical Measurements, vol. iv. p. 401, which probably was written for the Supplement to the former edition of this work, before Dr Wollaston had described his thermometrical barometer in the Philosophical Transactions for 1817. But at the Dublin meeting of the British Association, Colonel Sykes, after objecting to this refined apparatus, as expensive, and so fragile as to be extremely liable to accidents in travelling on mountains, described a variety of very satisfactory measurements which he had made with common thermometers.

Rule for adjusting thermometers to these.

As artists may be obliged to adjust thermometers under very different pressures of the atmosphere, M. Deluc, in his *Recherches sur les Mod. de l'Atmosphere*, from a series of experiments, has given an equation for this difference, in Paris measure, which has been verified by Sir George Shuckburgh; who, as well as Dr Horsley and Dr Maskelyne, has adapted the equation and rules to English measures, and reduced the allowances into tables. Dr Horsley's rule deduced from Deluc's is this:

$$\frac{99000}{899}\log.\, z - 92{\cdot}804 = h,$$

where h denotes the height of a thermometer plunged in boiling water above the point of melting ice, in degrees of Fahrenheit, and z the height of the barometer in 10ths of an inch. From this rule he has computed the correction in the second column of the following table:

Barometer.	Deluc's Correction.	Difference.	Shuckburgh's Correction.	Difference.
	°		°	
26·0	— 6·83		— 7·09	
26·5	— 5·93	·90	— 6·18	·91
27·0	— 5·04	·89	— 5·27	·91
27·5	— 4·16	·88	— 4·37	·90
28·0	— 3·31	·87	— 3·48	·89
28·5	— 2·45	·86	— 2·59	·89
29·0	— 1·62	·83	— 1·72	·87
29·5	— 0·80	·82	— 0·85	·87
30·0	0·00	·80	0·00	·85
30·5	+ 0·79	·79	+ 0·85	·85
31·0	+ 1·57	·78	+ 1·69	·84

In the first column is the height of the barometer, in inches. The second shows the correction to be applied, according to the sign, to 212° of Fahrenheit, to find the true boiling point, which for all intermediate states of the barometer may be had with sufficient accuracy by taking proportional parts. The fourth column contains a correction for the same purpose, according to the experiments of Sir George Shuckburgh. See Philosophical Transactions, vol. lxiv. art. 20 and 30.

The temperature of steam in a nearly closed vessel is more steady, and slightly lower than that of boiling water; and the latter is from 2° to 4° higher in a glass vessel than in one of metal. It is of material importance that the water be pure, because foreign substances are apt to affect both the freezing and boiling points.

Committee of Royal Society on the fixed points.

The Royal Society, fully apprised of the importance of adjusting the fixed points of thermometers, appointed a committee to consider the best method for this purpose. See Philosophical Transactions, vol. lxvii. part ii. art. 37.

Although the boiling point be placed rather higher on some thermometers than on others, this produces very little error in observations on the weather, at least in this climate; for an error of 1½° in the boiling point will make an error only of half a degree in the position of 92°, and of not more than a quarter in that of 62°. It is only in nice experiments, or with hot liquors, that this can be of importance. In adjusting the freezing as well as the boiling point, the tube ought to be kept of the same temperature as the ball. Many a thermometer, whilst undergoing this operation, has little more than the bulb immersed in the bath which is to give the requisite temperature, the stem being just allowed to take its chance of holding some unknown temperature intermediate between those of the bath and of the air. The indications of such an instrument, though pretty well adapted for ordinary chemical purposes, must be somewhat uncertain. But it is evidently impossible to apply a correction for this, either to an instrument so vaguely graduated, or indeed to the very best of thermometers when used with the stem at an unknown temperature; so that tables formed upon the idea that the stem has always the same temperature as the air of the apartment, cannot be expected to afford the proper correction, especially considering how rapidly hot air and vapour may rise around the stem, from a hot liquor. A mode of lessening this error will afterwards be noticed.

In the ordinary manufacture of thermometers, it is reckoned sufficient to place the new instrument horizontally in a bath along with a standard thermometer, and to mark on it the corresponding degree, or part of a degree; next, either to change the temperature of the same bath, or to put the instruments together into a bath of a different temperature, marking the degree as before. The space between the two points so marked is then divided equally into the corresponding number of degrees (regard of course being had to any fraction), and the like division, if neces-

Thermometer.

sary, is extended both ways beyond the two points. This method, however, does not provide against any inequality in the bore of the tube. But it is obvious that any error from such inequality might be obviated by marking a sufficient number of points at different temperatures; and also that by the same means an alcohol thermometer may be graduated to agree with a mercurial one, notwithstanding their very different rates of expansion. This we should think greatly preferable to the perpetual application of corrections for their difference. However, when an alcohol thermometer does require a correction, this ought to be effected by means of a table formed from actual comparison with a good mercurial one; because alcohol thermometers differ so much among themselves that no general table can be applicable to all. See Dr Richardson's remarks, with examples of this, in Journal of the Royal Geographical Society, vol. ix. p. 332.

As the division of the scale is an arbitrary matter, thermometers differ much in this circumstance. Fahrenheit made 180 degrees between the freezing and boiling water points, Celsius made 100, Reaumur 80, Amontons 73, and Newton only 34. For a general comparison of various scales, see fig. 4. A very accurate method of verifying the scales of thermometers, and an example of the discordance of two standard thermometers, are given by Professor Forbes in the Philosophical Transactions for 1836, p. 577. The history of several thermometers is briefly given in the article BAROMETER, and a description of the Differential Thermometer, and of metallic thermometers, will be found under the article METEOROLOGY. For a differential thermometer Dr Marshall Hall employs a mercurial thermometer, with a very minute bore and large degrees; and to avoid an inconveniently long tube, he has a ball at the top, into which he can at pleasure throw up a portion of the mercury. But, owing to the quantity of mercury actually used being thus rendered variable and uncertain, the indications of such an instrument are not comparable with those of a common thermometer. About twenty years ago, the journals announced a great improvement which Dr Howard had made on Leslie's differential thermometer, by substituting alcohol for sulphuric acid. But had the learned doctor been sufficiently acquainted with the subject, he would have known that Leslie had purposely avoided using any liquid which sensibly emits vapours; because a variable quantity of elastic vapours mixed with the included air, must necessarily occasion similar but incomparably greater uncertainties than those in Dr Hall's instrument.

As to the point at which the scale ought to commence, various opinions have been entertained. If we knew the beginning or lowest degree of heat, all would agree that this ought to be the lowest point of the thermometer; but we know neither the lowest nor the highest degrees of heat; we observe only the intermediate parts. All we can do, then, is to begin it at some invariable point, to which thermometers made in different places may easily be adjusted. Fahrenheit began his scale at the point where snow and salt congeal. Kirwan and Blagden proposed the freezing point of mercury. Sir Isaac Newton, Hales, Reaumur, and Celsius, adopted the freezing point of water. Fahrenheit's zero is placed at an artificial cold which few can ever experience. There would be several advantages in adopting the freezing point of mercury. It is the lowest degree to which liquid mercury can be applied; and it would supersede the use of the signs plus and minus on a mercurial thermometer. But it is not a point well known, for few can have an opportunity of seeing mercury congealed. As to the abolition of negative numbers, it would not counterbalance the advantage of using a well-known point. Of heat and cold we can only judge by our feelings. The point, then, at which the scale should commence, ought to be one which can form to us a standard of heat and cold. Such is the freezing point of water chosen by Newton; for of all the general effects of cold it is the most remarkable. It therefore suits thermometers to be used all over the globe; for even in the hottest countries there are mountains perpetually covered with snow.

Thermometers generally used.

The thermometers at present in most general use, are Fahrenheit's in Britain, Holland, and North America; De l'Isle's in Russia; Reaumur's and the centigrade in France; and Celsius's, the same as the last named, in Sweden. They are generally filled with mercury. But here it may be proper to observe, that the mercurial thermometer which goes by the name of Reaumur's, was not in use till long after his time, and was first introduced by Deluc.

The relative values of the degrees of Fahrenheit F, of Celsius C, and Reaumur R, are expressed by the following formulæ.

$$F = 32 + \frac{9}{5}C = 32 + \frac{9}{4}R.$$

$$C = \frac{5(F-32)}{9} = \frac{5}{4}R.$$

$$R = \frac{4(F-32)}{9} = \frac{4}{5}C.$$

These expressions are perfectly general, proper regard being always had to the signs when any of the symbols become negative. The formulæ usually given in books of chemistry expressly for negative degrees are not simply useless, but so wild that they cannot fail to mislead and perplex those whom they are intended to guide. In Fahrenheit's scale it is seldom necessary to use either fractions or negative degrees, which is by no means the case with the other two. Instead of a single thermometer whose scale would extend from the freezing to the boiling point of mercury, or through nearly 720° F., and which must either be inconveniently long, or have exceedingly minute degrees, it is better to have several thermometers, each of which will in succession apply to a different part of the whole range, so as to embrace or share the whole among them. In this way, while the degrees may be large, the stem of each thermometer, containing but a small proportion of the whole mercury, will occasion so much the less error when its temperature differs from that of the bulb. Fig. 3 shows a thermometer adapted to the ordinary atmospheric temperatures. In thermometers intended for corrosive liquors, the divisions or degrees are sometimes marked on the bare glass. In some, either the scale does not extend quite down to the bulb, or a portion of it is made to fold up with a joint.

Change in the freezing point.

It is not improbable that the freezing points of many old thermometers may have originally been marked too low, either from using water cooled artificially, or the ice of brackish or of other impure water. At any rate, it is now found, that when placed in melting ice, they generally stand above their freezing points. But supposing this to be a real deterioration which has taken place during the lapse of time, the following would seem to be the most probable of the causes which have been assigned for it, particularly in mercurial thermometers. 1. A permanent contraction of the bulb, gradually induced by the excess of the atmospheric pressure over that within, owing to the air having been more or less expelled. 2. If, after the air has been entirely expelled from the bulb, either some of it still remain in the tube, although sealed, or the tube have been left quite open, the air will gradually insinuate itself again between the mercury and glass of the tube, till it at length enter the bulb and form a complete lining to the inside of the glass. By this means, the air, slightly displacing the mercury, will raise it higher in the stem. 3. A rather questionable change, independently of the preceding, is supposed gradually to take place for some time in the molecular structure of the glass. But why this process should contract rather than enlarge the bulb has never been explained; only we presume it could be prevented by previously annealing it properly. However, such of the original alcoholic thermometers of the *Academia del Cimento* as have been preserved and examined, are said to have undergone no change in their freezing points during a period of more than two hundred years, which rather argues against any change in the dimensions of the glass.

Self-registering thermometers.

As in meteorological observations it is necessary to attend to the greatest rise and fall of the thermometer, attempts have been made to construct instruments which might register the greatest degree of heat or of cold which took place during the absence of the observer. In 1757 Lord Charles Cavendish presented to the Royal Society a thermometer to mark the greatest heat, and another the greatest cold. The first consists of a glass tube AB, fig. 5, with a cylindrical bulb B at the lower end, and capillary at the top, over which is fixed a glass ball C. The bulb and part of the tube are filled with mercury, the top of which shows the degrees of heat as usual. The upper part of the tube above the mercury is filled with alcohol, and so is the ball C almost to the top of the capillary tube. When the mercury rises, the spirit of wine is also raised, and runs into the ball C, which is so made that the liquor cannot return when the mercury sinks; consequently the height of the spirit of wine in the ball, added to that in the tube, will give the greatest degree of heat to which the thermometer has pointed since last observation. To prepare for a new observation, the instrument must be inclined till the liquor in the ball cover the end of the capillary tube.

Lord C. Cavendish's.

The thermometer for showing the greatest cold is represented in fig. 6 by the crooked tube ABCD. It contains alcohol, together with as much mercury as fills both legs of the syphon, and part of the hollow ball C. The temperature is shown by the rise or fall of the mercury in the leg AB. When the mercury in the longer leg sinks by cold, that in the shorter will rise and run over into the ball C, from which it cannot return when the mercury subsides in the shorter and rises in the longer leg. The upper part of the shorter leg will therefore be filled with a column of spirits, of a length proportional to the increase of heat; the lower end of which, by means of a proper scale, will show how much the mercury has been lower than it is; which being subtracted from the present height, will give the lowest point to which the mercury has fallen. To prepare for a new observation, the mercury is made to run back from the ball into the shorter leg, by inclining the tube and heating the ball.

Six's thermometer.

Another self-registering thermometer was proposed by Mr Six in 1782. It is principally filled with alcohol, though mercury is also employed for supporting an index. *ab*, fig. 7, is a thin tube of glass, sixteen inches long and five sixteenths of an inch caliber: *cde* and *fgh* are smaller tubes, about one twentieth of an inch caliber. These three tubes are occupied with alcohol, except the space between *d* and *g*, which is filled with mercury. As the alcohol contracts or expands in the middle tube, the mercury falls or rises in the outside tubes. An index, represented in fig. 8, is placed on the surface, within each of these tubes, so light as to float upon it. *k* is a small glass tube three fourths of an inch long, hermetically sealed at each end, and enclosing a piece of steel wire. At each end *l*, *m*, of this small tube, a short tube of black glass is fixed, of such a diameter as to pass freely up and down within each of the outside tubes *ce* or *fh* of the thermometer. From the upper end of the index is drawn a spring of glass to the fineness of a hair, which presses lightly against the inner surface of the tube, and prevents the index from descending when the mercury descends. When the alcohol in the middle tube expands, it presses down the mercury in the tube *hf*, and consequently raises it in the tube *ec*; so that the index on the left-hand tube is left behind and marks the greatest cold, and the index in the right-hand tube rises and marks the greatest heat.

Dr Rutherford's register thermometers, which are more generally used than any other, are described in the article METEOROLOGY, and in the Transactions of the Royal Society of Edinburgh, vol. iii.

Keith's thermometer.

The following ingenious contrivance by Mr Keith of Ravelstone, besides being well adapted for marking the maximum and minimum, may also be employed to register the temperature in a continuous form for almost any length of time. AB, fig. 9, is a thin glass tube about fourteen inches long and three fourths of an inch caliber, close or hermetically sealed at top. To the lower end, which is open, is joined the crooked glass tube BE, seven inches long and four tenths of an inch caliber, and open at top. The tube AB is filled with alcohol, and the tube BE with mercury. This is properly an alcohol thermometer, and the mercury is used merely to support a float E of ivory or glass, with a wire EH for raising one index or depressing another, according as the mercury rises or falls. The float-wire, by means of an eye at *a*, moves easily along the small harpsichord wire GK. L, L′ are the two indexes, made of thin black oiled silk, which slide up or down with a very slight force. The one above the knee points out the greatest rise, and the one below shows the greatest fall, of the thermometer.

To prepare for an observation, both indexes are brought close to the knee H. It is evident, that when the mercury rises, the knee of the float-wire will carry with it the upper index L. When the mercury again subsides, it leaves the index, which will not descend by its own weight. As the mercury falls, the float-wire brings along with it the lower index L′, which it leaves behind as it had formerly left the upper. The scale to which the indexes point is placed parallel to GK. A cylindrical glass cover is placed over the part GF.

The continuity of the register is to be effected by attaching to the float-wire a soft pencil, which is to bear lightly upon a cylinder covered with paper, and revolving on a vertical axis by means of clock-work, once in a month. At each month's end the paper is to be removed and a clean one put in its place. The paper is to be ruled horizontally with a set of lines to mark the degrees, as on the scale of a thermometer; and also vertically with lines to note the days of the month, and other smaller divisions of time. See Transactions of Royal Society of Edinburgh, vol. iv.

Owing to the moving force in metallic thermometers becoming so exceedingly feeble at the outstretch, that the least resistance will make them stop too soon, and then perhaps let them go too far by a start, they are not well suited for register thermometers, though often recommended for this purpose. But Dr Ure's "thermostat," for regulating temperature (Dictionary of Manufactures), depends on the same principle.

Balance thermometer.

Various schemes have at different times been proposed for poising a thermometer so nicely across an axis, that a very slight change of temperature should disturb the equilibrium sufficiently to produce a very sensible change in the position of the instrument. Register thermometers in this form are liable to the same objection as the metallic sort. But the principle of the balance has been employed in various forms, and on a large scale, for opening and shutting doors to regulate the temperature of apartments, by admitting just the requisite quantity of cold air. For this purpose, Dr Cumming suspended and counterpoised a large ball and tube containing air, and having its open end immersed in a cistern of mercury. The arrangement was such, that as the ball rose or fell with the expansion or contraction of the included air, it closed or opened the door or window of the apartment. To obviate the effect of changes of atmospheric pressure, the counterpoise carried a large barometer tube, which also was immersed in mercury, and had its upper part empty like any common barometer.

A species of thermometer contrived for observing the force of solar radiation, and named an actinometer, consists of a large hollow cylinder of glass, having its upper end contracted and joined to a thermometer tube, terminated at the top in a ball drawn out to a point, and broken off, so as to leave a small orifice. The lower end of the cylinder is closed by a silver or silver-plated cap cemented on it, and furnished with a screw, also of silver, passing through a collar of waxed leather, which is pressed into forcible contact with its thread, by a tightening screw of large diameter enclosing it, and working into the silver cap by the aid of a strong key or wrench. The cylinder is filled with a deep-blue liquid, ammonio-sulphate of copper, and the ball at the top being left purposely full of air, and the point closed with melted wax, it becomes, in any given position of the screw, a thermometer of great delicacy, the tube being furnished with a graduated scale. The cylinder is enclosed in a chamber blackened on three sides, and on the fourth or face defended from currents of air by a thick glass, removeable at pleasure. The design of the screw is to vary at pleasure the capacity of the cylinder, and thus to drive, if necessary, a portion of the liquid up into the ball, which acts as a reservoir, or, if necessary, to draw back from that reservoir such a quantity as shall just fill it, leaving no bubble of air in the cylinder.

To use the instrument, examine, first, whether there be any air in the cylinder, which is easily seen by holding it level and tilting it, when the air, if any, will be seen to run along it. If there be any, hold it upright in the left hand, and the air will ascend to the root of the thermometer tube. Then, by alternately tightening and slackening the screw with the right hand, as the case may require, it will always be practicable to drive the air out of the cylinder into the ball, and suck down liquid, if any, from the ball to supply its place, till the air is entirely evacuated from the cylinder, and the latter, as well as the whole stem of the thermometer tube, is full of the liquid in an unbroken column. Then, holding it horizontally, face upwards, slowly and cautiously turn back the screw, till the liquid retreats to the zero of the scale. The observer must station himself in the sunshine, or in some sharply terminated shadow, so that without inconvenience, or materially altering his situation, or the exposure of the instrument in other respects, he can hold it at pleasure alternately in full sun and total shadow, and by that means find the difference in the effects, or the force of solar radiation. If placed in the sun, he must be provided with a screen of pasteboard or tin plate, large enough to shade the whole of the lower part or chamber of the instrument, from which it should not be less than two feet distant, and should be removeable in an instant. But farther details and examples in the use of this and various other meteorological instruments will be found in the Report of the Royal Society (August 1839), on the Instructions for the Scientific Expedition to the Antarctic Region.

Ever since Dulong and Petit published their valuable researches on heat (some of which have been particularly discussed under the article PYROMETER), and in which they have made the air-thermometer the standard of temperature, their example in the latter respect has been so very generally followed, as to render it of importance to ascertain whether the adoption of such a standard can consist with other admitted principles; more especially since the theory of the air-thermometer, as usually laid down in first-rate books on the subject, is full of contradiction. We shall therefore now endeavour to set the matter in a proper light, employing for this purpose the same data, and nearly the same notation, as those with which Baron Poisson commences his memoir in the *Annales de Chimie*, tome xxiii. p. 337.

Let ϱ be the density of the air, p the pressure, and θ the temperature in degrees of any common scale of an air-thermometer; then a being ·00208 if Fahrenheit's scale be employed, and b another constant, we have $p = b\varrho\,(1 + a\theta)$. This is commonly called the law of Mariotte, but was first discovered by Hooke when assistant to Boyle. With the centigrade scale, a would be ·00375; but both values of it would need to be slightly lessened if they were wished to agree with Rudberg's experiments on the expansion of air (Poggendorff's *Annalen*, xli. and xliv.), which perhaps require confirmation. Fortunately the present investigation has no dependence on the precision in the values of any constants. Let q be the difference between the total quantity of heat which a given mass of air may contain under the pressure p and temperature θ, and that which it contains under a pressure and temperature chosen arbitrarily. Then the specific heat of the air, or that which would raise its temperature one degree, being directly as dq, and inversely as $d\theta$, may be expressed by $\frac{dq}{d\theta}$. When such rise takes place under a constant pressure, we have from the above equation, with p constant, $d\theta = -\,d\varrho \times \frac{1 + a\theta}{a\varrho}$: and when under a constant volume, or with ϱ constant, $d\theta = dp \times \frac{1 + a\theta}{ap}$. The specific heat, when the pressure is constant, will therefore be $-\frac{dq}{d\varrho} \times \frac{a\varrho}{1 + a\theta}$; and with the volume constant, $\frac{dq}{dp} \times \frac{ap}{1 + a\theta}$. Now, from the experiments of Gay Lussac and Welter, which were carried through a great range both of temperature and pressure (*Mécanique Céleste*, v. 97 and 127), it appears that the former of these two specific heats always exceeds the latter in a constant ratio, which, if it be called that of k to 1, we shall have

$$\varrho\frac{dq}{d\varrho} + kp\frac{dq}{dp} = 0 \ldots\ldots\ldots\ldots\ldots\ldots (\mathrm{A}).$$

Thus far the process does not materially differ from that pursued by Poisson and several other foreign mathematicians; but on integrating this equation, their next step is to modify the integral to suit the common theory of the air-thermometer, which assumes the variations of absolute heat to be proportional to those of the volume under a constant pressure. In this they do not seem to have been aware that equation (A) is utterly incompatible with any such assumption, as we shall now endeavour to explain. For it is evident that the value of dq in the first term of the equation, is always to dq in the second, as $-\frac{d\varrho}{\varrho}$ to $\frac{dp}{kp}$; whereas, if not only the differential of absolute heat in air under a constant pressure had been proportional to $-\frac{d\varrho}{\varrho^2}$, the differential of the volume, but if, in like manner, (as the common theory, when coupled with the constancy of the ratio of k to 1, assumes), the differential of heat under a constant volume had varied as dp the differential of the pressure, then the value of dq in the first term would necessarily have been to that in the second as $-\frac{d\varrho}{\varrho^2}$ to Ndp, where N is a constant. Now each of the former ratios is obviously the same with that of $-\frac{d\varrho}{\varrho^2}$ to $\frac{dp}{k\varrho p}$, which cannot coincide with the ratio of $-\frac{d\varrho}{\varrho^2}$ to Ndp, unless $\mathrm{N} = \frac{1}{k\varrho p}$; that is, unless the product of the density into the pressure always form a constant quantity, which is extremely absurd. But it is equally clear, that if any other ratio which differs from the first one were assumed to subsist among the differentials, it must lead to the like absurdity of requiring some of the quantities to be both variable and constant at the same time. Whoever therefore admits the law of Mariotte, and the *constancy* in the ratio of the specific heats, has no alternative but to reject the common graduation, and indeed every other which would not make the differentials of heat follow the same proportion as do those of the logarithms of the volume and of the pressure, compounded of course with the ratio of k to 1. Hence the only function of the integral of equation (A) which can consist with the data is

$$q = \mathrm{A} + \mathrm{B}\left(\frac{1}{k}\log. p - \log. \varrho\right) \dots\dots\dots (\mathrm{B}),$$

where A and B are constants. This shows plainly that, under a constant pressure, air expands in geometrical progression for equal increments of heat, as has been deduced from the same data by a very different process under the article HYGROMETRY, and where it is shown that the value of k is most probably 1·3333.

Extravagant as are the inconsistencies which necessarily result from coupling any of the common scales of temperature with the two principles above specified, yet this singular oversight, from its having originated in a work of no less authority than the *Mécanique Céleste* (v. p. 128), has been implicitly copied into almost every subsequent production on the same subject. For example, we find it pervading the very valuable and extensive writings of Baron Poisson, whose recent decease science has now to deplore; as also those of Navier, and of other eminent French writers, whenever they have occasion to treat on heat or sound. But a most notable instance of the sort is to be found in Mr Lubbock's recent treatise On the Heat of Vapours, as will presently be noticed.

Since $d\varrho$ will vanish and change its sign in the first term of equation (A) just when dq in that term does so, it is evident that, although the first term may occasionally take the form of a vanishing fraction, it will never vanish nor change its sign. For a similar reason, the second term of equation (A) will never vanish nor change its sign. But since the sum of the two values of dq, regard being had to their signs, will be a measure of the rate at which the air may be gaining or losing heat; so it is only when those two values of dq are equal, and with contrary signs destroy each other, making, as it were, the decrement of heat annihilate the increment, that the absolute heat can be constant. In that case, which may imply the sudden compression or dilatation of air, equation (A) admits of being greatly simplified; because both terms being then divisible by the same value of dq, we have $-\frac{d\varrho}{\varrho} = \frac{dp}{kp}$. Hence $k \log. \varrho = \log. p + \mathrm{C}$; so that if the initial values of ϱ and p be called ϱ' and p', we shall have $\mathrm{C} = k \log. \varrho' - \log. p'$; and $k \log. \frac{\varrho}{\varrho'} = \log. \frac{p}{p'}$, or $\left(\frac{\varrho}{\varrho'}\right)^k = \frac{p}{p'}$, as might likewise have been readily deduced from equation (B). But we have taken this other method that it might be clearly seen what a mistake some are in who suppose equation (A) to be restricted to the case in which the absolute heat is constant. For it is now evident that under such a restriction there could have been no use whatever in that equation containing dq, or indeed in its having the partial differential form at all. However, through some inadvertency, Mr Lubbock has so seriously misconstrued the investigations of the foreign mathematicians as to allege that their "theorems rest upon the condition that the absolute is constant while the sensible heat varies. This," says he, "is the most restricted hypothesis which can be made upon the nature of heat." Now we presume that if such an able mathematician as Mr Lubbock had only paid a little more attention to the writings of these authors, he would have found that they have restricted themselves to no such hypothesis. For although they have not overlooked the particular case just alluded to, in which air may be so suddenly compressed or dilated as to have its temperature altered without the absolute heat having had time either to gain or lose, they have treated the subject in a sufficiently general manner to include every other case. Thus it was by means of the variable part of the integral of equation (A) that they intended to express the change of absolute heat which may at any time accompany a change in ϱ, in p, or in both together; and this they might have done quite consistently, had they not unfortunately modified the integral into the form $\mathrm{A} + \mathrm{B}\frac{p^{\frac{1}{k}}}{\varrho}$, with the view of making it embrace the common theory of temperature. But the most curious thing in the whole is, that Mr Lubbock has, after all, borrowed from them this very formula to be a principal link in his investigation, and then coupled it of new with an additional expression to embrace the theory just mentioned, as if the latter had not already had a sufficient share in it. See Phil. Magazine for May 1840, p. 439.

Since the constancy in the ratio of the specific heats enables us to distinguish between the heat which is absorbed in the enlargement of the volume, under a constant pressure, and that which alone raises the temperature; showing the latter to exceed the former in the constant ratio of 1 to $k - 1$; it is evident, that if at any stage of a very extensive increase of temperature, the expansion were to cease, the increment of heat which could add the next degree to the temperature would be the same, no matter what volume the air had by this time acquired; and that such increment would be equal to the decrement of heat for each successive degree of a uniform scale, were the enlarged volume of air now cooled down to the first temperature without suffering any contraction; so that the specific heat is in all cases independent of the magnitude of a constant volume. However, Professor Kelland, without adducing any proof, asserts in his Theory of Heat, that the specific heat is greater with a greater volume, which we now see to be utterly incompatible with the constancy in the ratio of the specific heats, a principle which he also admits and employs. The like may be said of his coupling this principle with the common scale of temperature, and also of his asserting that, in the sudden compression of air, the increase of temperature measured by that scale is proportional to the diminution of the volume; whereas it is the changes in their logarithms that are proportional, as is shown under our articles HYGROMETRY and SOUND. At first sight, and indeed until some adequate means be used to test the soundness of such cases as the preceding, every thing in them may seem to be quite correct. Perhaps opposite errors may have destroyed each other, as sometimes happens from discarding or adopting, at certain stages of the process, quantities which may then seem quite inconsiderable, but which ultimately have sufficient influence to change the character of the final result. It is in this way that in the Theory of Heat (p. 93–95) results have been obtained which it is utterly impossible to deduce from the same data by any legitimate reasoning; as will be found to have been long since shown in the discussion of a similar case in the Edinb. Phil. Journal for July 1827, p. 154. (E. E. E.)

THERMOMETER, *Differential.* See the preceding article, and BAROMETER, CLIMATE, COLD, and METEOROLOGY.

THERMOPYLÆ, a narrow pass or defile, between the

Sinus Maliacus on the east, and a steep branch of Mount Œta, covered with unpassable woods, on the west; leading from Thessaly to Locris and Bœotia. These mountains divide Greece in the middle, in the same manner as the Apennine does Italy; forming one continued ridge from Leucate on the west, to the sea on the east, with thickets and rocks interspersed. The valley is of small breadth, and completely occupied by a marsh, through which it is impossible for horse or foot to penetrate. Through the middle of this marsh a paved road was made by the Greeks, which still remains, and affords the only path to Greece from Thessaly. The Thermæ or hot springs, from which the place had its name, are near the narrowest part of the pass; and their temperature was found by Dr Clarke to be 111 degrees. At the south entrance of the defile is a small eminence, on which he found a tumulus, with the remains of a massive pedestal of red breccia much time-worn, and evidently the tomb of the 300 Spartans to whose immortal memories this monument was consecrated. The rising ground on which the monument stands is the spot where the Spartans fell. The remains of the wall which shut up the pass are also yet visible.

THERWARA, a town of Hindustan, in the province of Gujerat, thirty miles north-west from Rahdunpoor.

THESEA, feasts celebrated by the Athenians in honour of Theseus, consisting of sports and games, with mirth and banquets. Such as were poor and unable to contribute to them were entertained at the public expense.

THESEUS, a famous hero of antiquity, ranked among the demigods, whose history is fabulous. He was the reputed son of Ægeus king of Athens. He threw Sciron, a cruel robber, down a precipice; fastened Procrustes, tyrant of Attica, to a bending pine, which being let loose, tore him asunder; killed the Minotaur kept in the labyrinth by king Minos, in Crete; and by the assistance of that prince's daughter, Ariadne, who gave him a clue, escaped out of that labyrinth, and sailed with his deliverer to the isle of Naxos, where he had the ingratitude to leave her. Theseus afterwards overcame the centaurs, subdued the Thebans, and defeated the Amazons. He assisted his friend Pirithous in his expedition to the infernal regions to carry off Proserpine; but was imprisoned by Pluto, till he was released by Hercules. He is also said to have established the Isthmian games, in honour of Neptune; to have united the twelve cities of Attica; and to have founded a republic there, 1236 B. C. Some time after, taking a voyage into Epirus, he was seized by Aidonus, king of the Molossians; and in the mean time Menestheus rendered himself master of Athens. But at length Theseus being released from prison, retired to Scyros, where King Lycomedes caused him to be thrown from the top of a rock. Theseus had several wives; the first of whom was Helena, the daughter of Tyndarus; the second, Hippolyte, queen of the Amazons; and the last, Phædra, sister to Ariadne, who punished him for his infidelity to her sister, by her incestuous passion for his son Hippolytus.

THESIS, a general position which a person advances, and offers to maintain.

THESPIS, a famous Greek tragic poet, and the first representer of tragedy at Athens. He carried his troop from village to village in a waggon.

THESSALY, a country of Greece, the boundaries of which have been different at different periods. Properly speaking, Thessaly was bounded on the south by the southern parts of Greece, or Græcia Propria; east, by the Ægean; north, by Macedonia and Mygdonia; and west, by Illyricum and Epirus. It was generally divided into four separate provinces, Thessaliotis, Pelasgiotis, Istiæotis, and Phthiotis, to which some add Magnesia. It has been likewise called Æmonia, Pelasgicum, Argos, Hellas, Argeia, Dryopis, Pelasgia, Pyrrhæa, &c. The name of Thessaly is derived from Thessalus, one of its monarchs. Thessaly is famous for a deluge which happened there in the age of Deucalion. Its mountains and cities are also celebrated, such as Olympus, Pelion, Ossa, Larissa, &c. The Argonants were partly natives of Thessaly. The inhabitants of the country passed for a treacherous nation, so that false money was called *Thessalian coin*, and a perfidious action a *Thessalian deceit*. Thessaly was originally governed by kings, till it became subject to the Macedonian monarchs. It is bounded by Macedonia on the north, by the Archipelago on the east, by Achaia or Livadia on the south, and by Epirus on the west.

THETFORD, a town of the hundred of Shropham, in the county of Norfolk, eighty miles from London. It stands on a branch of the river Ouse, and consists of three parishes. It was formerly much more extensive than it is at present, and in the reign of Edward the Third it contained twenty churches, eight monasteries, and six hospitals. Many of the remaining buildings exhibit marks of great antiquity, though the town is not otherwise remarkable. The county assizes are held here once in each year. Thetford is a borough, with a mayor, four aldermen, and eleven councillors, and it returns two members to parliament. There is some little trade by the Ouse with Lynn. The inhabitants amounted in 1821 to 2922, and in 1831 to 3462.

THETIS, in Pagan mythology, the wife of Oceanus, and the mother of Nereus and Doris, who were married to each other; and from this marriage sprung the nymphs of the earth and sea. Among the sea-nymphs there was one named Thetis the younger, who excelled all the rest in beauty, and for whom Jupiter conceived such a passion, that he resolved to espouse her; but being informed by the Destinies that she would bring forth a son who would rise above his father, he married her to Peleus. To their nuptials all the gods and goddesses were invited except Discord, who, to be revenged for this contempt, threw a golden apple into the assembly, on which was engraven, *For the Fairest*. Juno, Pallas, and Venus, disputed for this apple; but Paris being chosen to decide the difference, adjudged it to Venus. From this marriage of Thetis and Peleus sprung Achilles.

THEURGY, θεουργία, a name which the ancients gave to that sacred part of magic which we sometimes call *white magic*, or the *white art*. The word is formed from Θεὸς, *God*, and ἔργον, *work;* q. d. the art of doing divine things; or the power of working extraordinary and supernatural things, by invoking the names of God, saints, angels, &c. Accordingly, those who have written of magic in general, divide it into three parts: the first of which is called *theurgy*, as operating by divine or celestial means; the second *natural magic*, performed by the powers of nature; and the third, comprehending *necromancy*, *sorcery*, and *witchcraft* or *magic*, performed by the assistance of demons or departed men.

THIAGUR, a town of Hindustan in the Carnatic. It is fifty-six miles west by south from Pondicherry. Long. 79. 12. E. Lat. 11. 45. N.

THIERS, an arrondissement of the department of the Puy de Dome, in France. It is 334 square miles in extent, and comprehends six cantons and thirty-nine communes, having 70,657 inhabitants in 1836. The capital is the city of the same name, and is built on the side of a hill, at whose base flows the river Durolle. It contained in the same year three churches, and 9982 inhabitants. It is a seat of the hardware and cutlery trade; and at one time fabricated considerable quantities of inferior jewellery and gilt toys. Long. 3. 27. 47. E. Lat. 45. 51. 27. N.

THIMBRIC-KOUY, a village of Asiatic Turkey, in Anatolia, on the site of the ancient Thymbra, where considerable ruins are still found.

THIONVILLE, an arrondissement of the department

Thirlwall || Thistle, Order of the.

of the Moselle, in France, extending over 408 square miles. It is divided into five cantons, and these into 117 communes, having a population of 87,520 persons in 1836. The capital is the city of the same name, situated on the right bank of the Meuse. It is one of the strongest of the frontier fortified places of France, and was attacked by the Prussians in 1792, but without success. In 1836 it contained 5680 civil inhabitants, principally employed in the manufacture of hats and hosiery. Long. 6. 5. 25. E. Lat. 49. 21. 30. N.

THIRLWALL, a hamlet within the parish of Haltwhistle, in the west division of the ward of Tindal, in the county of Northumberland. It is remarkable from being situated on the Picts' wall, at the place where the Scots made gaps to force a passage into England. It has an ancient castle built on the north side of the wall, about twenty yards long and twelve broad, with walls nine feet thick. It is curiously vaulted underneath, and on the top are six small turrets. Though this place had in 1831 only 328 inhabitants, they have rapidly increased, and are still increasing, in consequence of the railway from Carlisle to Newcastle, which passes by it, and from the extensive fields of coal which are in its neighbourhood.

THIRSK, a town of the wapentake of Birdforth, in the north riding of the county of York, 223 miles from London. It is situated on the river Coldbeck, by which it is divided into two parts. The town has some trade in making coarse linens and sackings. It is an ancient borough, and returns one member to parliament. The church is a fine old building. There are also various places of worship for dissenters. There is a market on Monday, and several fairs. The inhabitants amounted in 1821 to 3502, and in 1831 to 3829.

THIRSTY SOUND, an inlet or bay on the east coast of New Holland. Long. of the northernmost point, 150. 0. 10. E. Lat. 22. 6. 53. S.

THISTLE, ORDER OF THE, or *of St Andrew*, a military order of knighthood in Scotland, the rise and institution of which are variously related by different authors. Lesley bishop of Ross reports, that the night before the battle between Athelstan king of Northumberland and Hungus king of the Picts, a bright cross, in form of that upon which St Andrew (the tutelary saint of Scotland) suffered martyrdom, appeared to Hungus; who, having gained the victory, ever after bore the figure of that cross on his banners. Others assert, that Achaius king of Scotland first instituted this order, after having made the famous league offensive and defensive with Charlemagne king of France. But although the thistle had been acknowledged as the symbol of the kingdom of Scotland from the reign of Achaius, yet some refer the beginning of this order to Charles VII. of France. Others place the foundation of it as low as the year 1500. The chief and principal ensign is a gold collar composed of thistles and sprigs of rue interlinked with amulets of gold, having as a pendant the image of St Andrew with his cross, and the motto NEMO ME IMPUNE LACESSET, "Nobody shall provoke me with impunity." The ordinary or common ensign worn by the knights is a star of four silver points, and over them a green circle, bordered and lettered with gold, containing the said motto, and in the centre is a thistle; all which is embroidered on their left breast, and worn with the collar, with a green ribband over the left shoulder, and brought under the right arm: the pendent image of St Andrew, with his cross, in a purple robe, is within an oval of gold enamelled vert, with the former motto; but sometimes they wear, encircled in the same manner, a thistle crowned. About the time of the Reformation, this order was dropped, and James II. of Great Britain resumed it, by creating eight knights. The Revolution again unsettled it; and it lay neglected till Queen Anne, in 1703, restored it to the primitive design, of twelve knights of St Andrew.

Thistle's Island || Thomas of Erceldoune.

THISTLE'S ISLAND, an island on the south coast of New Holland, at the mouth of Spencer's Gulf. It is about twelve miles long. Long. of the north end, 136. 3½. E. Lat. 34. 56. N.

THOMAR, a corregimiento in the province of Estremadura, in Portugal, on the borders of Beira and Alentejo. It comprises twenty-six cities and towns, seventy-nine villages, and 21,748 dwellings, with 108,740 inhabitants. The capital is a city of the same name, on the small river Nabao, in a delightful country covered with olive and orange trees. It is well and regularly built. It has an ancient castle, four churches, four monasteries, a poor-house, a hospital, and 1100 houses, with 5400 inhabitants. From the oil produced there, they make abundance of soap; and some of them are occupied in making cotton goods. It stands on the site of the ancient city Nabancia, which was destroyed by the Moors.

THOMAS OF ERCELDOUNE, sometimes called Learmont, and sometimes the Rhymer, has long been recognized in the venerable character of a prophet and poet; but the history of his life and writings is involved in that degree of obscurity which may well be supposed to attend so remote an era of our literary annals. His very name is not ascertained beyond all doubt or controversy. According to Macpherson, the accurate editor of Winton, he received his surname of Learmont from Hector Boyce: but it seems unnecessary to suppose that the inventive faculties of this historian were so unprofitably exercised; and if credit is due to an excellent genealogist, his family name is sufficiently established by its occurrence in authentic documents. In one charter, says Nisbet, he is called Thomas Rymor, but in others of an earlier date, Thomas Learmount of Ercildoun. Certain however it is that no writer who preceded Boyce has yet been found to describe him by the surname of Learmont: by Robert of Brunne, Barbour, Winton, Bower, and Mair, he is named Erceldoune, while Henry the blind poet designates him Thomas the Rhymer. In a charter granted to the Trinity House of Soltra, the poet's son describes himself as Thomas of Ercildoun, the son and heir of Thomas *Rymour* of Ercildoun; but whether this addition is to be considered as an ordinary surname, or as an epithet commonly applied in allusion to the father's poetical character, cannot be positively determined. It must at least be recollected that Rymer is a surname in both parts of the island, and that it has been traced to the poet's own age, and to the particular district in which he resided. Thomas the Rhymer is the name by which he continues to be best known among the common people of Scotland. Erceldoune, from which he derived his other appellation, is a village situate in the county of Berwick, at a small distance from Melrose; and the western extremity of this village still exhibits the ruins of a tower which was once honoured by his residence. His estate was afterwards acquired by the earl of March, who at the opposite end of the village possessed another place of strength, called the Earl's Tower; and hence the ancient name of Erceldoune is supposed to have been gradually corrupted into Earlstoun.

The period of his birth it seems impossible to ascertain; but it is evident that he must have reached the height of his reputation about the year 1286, the date of his famous prophecy respecting the death of Alexander the Third; and in the year 1299, his son and heir conveyed the estate of Erceldoune to the convent of Soltra. It is therefore obvious that his father must have died during the interval. Patrick Gordon refers his death to the year 1307, but this cannot be considered as any competent authority. An individual who enjoyed the reputation of a prophet may naturally be supposed to have attained a venerable age. Whether he himself aspired to the character of a prophet, it must now be fruitless to enquire; but it is at least certain, hat such a character was long attached to his name. Barbour, who wrote about the year 1370, makes a distinct allusion to "Thomas prophecy of Hersildoune." Bower, the continuator of the Scotichronicon, who flourished about the ear 1430, has furnished us with a circumstantial detail respecting Thomas's prediction of the king's premature death. Vinton and Henry have likewise represented him as enowed with the spirit of divination; and they are equally ubious as to the origin of the power which they acknowedge him to have possessed. Mair and Boyce have inerted in their respective histories, the tale so circumstanally related by Bower; but, with his usual good sense, the ormer subjoins, "To this Thomas our countrymen have scribed many predictions, and the common people of Briain yield no slight degree of credit to stories of this nature; hich I for the most part am accustomed to treat with ridiule." Lesley commemorates Michael Scott and Thomas earmont as personages of an extraordinary character; and e also hints at the famous prediction of the king's death. ut the period of the union of the crowns seems to have een the crisis of his reputation as a prophet; for, as we arn from Robert Birrel, "at this time all the haill comons f Scotland that had red or understanding, wer daylie speikng and exponeing of Thomas Rhymer his prophesie, and of ther prophesies quhilk wer prophesied in auld tymes." Of e collection which includes the prophecies ascribed to homas, the earliest edition that has hitherto been traced as printed by Robert Waldegrave in the year 1603. It as reprinted by Andrew Hart in 1615: the subsequent ditions are very numerous; and the collection still connues to be printed for the worshipful company of flying tationers.

The claims of Thomas of Erceldoune to the character of prophet, do not seem to require any further investigation; ut his claims to the character of a poet may perhaps be onsidered as more legitimate. That he was admired for is poetical talents, is supposed to be established by the estimony of a writer who approached very near his own ge: Robert of Brunne, who flourished about the year 1303, believed to commemorate the same Thomas of Erceloune as the author of an incomparable romance on the tory of Sir Tristrem. A romance of this description, and oubtless of a very early date, was discovered in the Auchineck MS. belonging to the Advocates Library; and of this ery curious relique of British literature, an elaborate and aluable edition, including all the necessary illustrations, was ublished by Sir Walter Scott in the year 1804. The disnguished editor entertained no doubt of its being the enuine production of Thomas of Erceldoune; but the upposition, we must confess, appears liable to many doubts nd difficulties. This metrical romance, to whatever author may be attributed, is deservedly regarded as a precious elique of early British, we do not venture to say Scotish, oetry. It is highly curious as a specimen of language, and ot less curious as a specimen of composition. The verses re short, and the stanzas somewhat artificial in their strucure; and amid the quaint simplicity of the author's style, e often distinguish a forcible brevity of expression. But is narrative, which has always a certain air of originality, sometimes so abrupt as to seem obscure, and even enigatical.[1] (x.)

THOMASTOWN, an ancient borough in the county of ilkenny, Ireland, situated on the river Nore, which is ere crossed by a handsome stone bridge. Its position on navigable river renders it well adapted for trade, and in some degree it acts as the port to the city of Kilkenny. The town contains the ruins of an old monastery, to which is attached the parish church. It is distant from Dublin sixty miles, and in the year 1831 its population amounted to 2871.

Thompson, Count Rumford.

THOMPSON, SIR BENJAMIN, COUNT RUMFORD, a well-known natural philosopher and political economist, was born in 1753, at a village in New Hampshire, then called Rumford, and now Concord. His father died while he was very young, and his mother married another man, who banished him from her house almost in his infancy: he inherited only a small pittance from an uncle, who died soon after his father. A clergyman named Bernard showed him great kindness, and taught him some of the higher mathematics at an early age, so that at fourteen he was able to calculate and delineate an eclipse of the sun. He had been intended for some commercial employment, but he preferred the pursuit of literature in any form: he attended the lectures of Dr Williams, and afterwards those of Dr Winthrop the astronomer, at Harvard College; and while he was still a stripling, he was established in the temporary occupation of a village schoolmaster; hoping, however, for an early opportunity to engage in some more agreeable employment: and at nineteen, he was fortunate enough to obtain the hand of Mrs Rolfe, daughter of Mr Walker, a clergyman, who had been employed with considerable credit in conducting some public business. For a year or two he lived retired and happy; but having obtained a commission of major in the militia from the governor of the province, together with some other distinctions of a civil nature, he was consequently led to adhere to the party of the Royalists; and he was soon obliged, by the success of the Independent forces, to take refuge at Boston, then occupied by the English troops. It was in November 1773 that he secretly quitted his residence, leaving his wife, whom he never saw again, and his infant daughter, who joined him twenty years after in Europe. He was employed to raise a regiment for the king's service; but when Boston was evacuated in 1776, he was sent with some important despatches to England. Here he soon acquired the confidence of Lord George Germaine, then colonial secretary of state, and was appointed secretary of the province of Georgia, though he never exercised the office; but he remained attached to that department of the public service.

In 1777 he commenced his career as an experimental philosopher, by employing his leisure hours, during a visit to Bath, in making some experiments on the cohesive strength of different substances; and upon his return to London, he communicated them to Sir Joseph Banks, with whom he formed an intimate acquaintance, which he kept up throughout the remainder of his life. In 1778 he was admitted a fellow of the Royal Society, and he made in that year his first experiments on gunpowder. In order to pursue these experiments, he went, in 1779, on board of the Victory, of 110 guns, commanded by his friend Sir Charles Hardy. He passed the whole campaign on board the fleet; and the results of the observations which he then made, furnished the materials of a chapter which he contributed to Stalkart's Treatise on Naval Architecture. He added to it a code of signals for the navy, which was not published. In 1780 he was appointed under-secretary of state, and he was constantly employed, for some little time, in the office on the business of the war. He succeeded, by means of his American friends and agents, in raising a regiment of cavalry, called the King's American Dragoons, of

Thompson, Count Rumford.

which he was appointed lieutenant-colonel commandant; and this success induced him to go to America to serve with it. At Charlestown he was intrusted with the command of the remains of the cavalry of the British army. He speedily restored the discipline of the corps, and gained its confidence and attachment: he often led it against the enemy, and frequently with considerable success. He proceeded, in 1782, to New York, where he assumed the command of his own regiment, having received the colours from the hand of Prince William Henry. In the autumn, General Clinton was succeeded by Sir Guy Carlton, whose friendship and confidence he speedily obtained. His regiment was recruited from the fragments of several others, and he was sent for the winter to Huntingdon in Long Island. In 1783 he was chosen to conduct the defence of Jamaica, which was then threatened by the enemy; but the general peace superseded the necessity of the intended expedition.

After his return to England, he made great efforts in the cause of the loyalist officers, and he was successful in persuading the ministry to make a proper provision for them. He was himself raised to the rank of colonel, upon the recommendation of General Carlton, only two years after his appointment as lieutenant-colonel. He had acquired a strong predilection for a military life, and was desirous of being sent with his regiment to the East Indies; and when the regiment was reduced, he wished to serve with the Austrians in a war which was then meditated against the Turks. With this view he left England in September 1783, and on his passage to Boulogne, he had an agreeable shipmate in the person of Gibbon the historian, who did justice to his merits as a "soldier, philosopher, and statesman." At Strasburg, his appearance on the parade in his uniform excited the attention of the late king of Bavaria, then Prince Maximilian of Deux Ponts, who invited him to his table, and being delighted with the accuracy and extent of his military knowledge, gave him a strong recommendation to his uncle, then elector; and instead of a day or two, as he had intended, he staid a fortnight at Munich. He was also very cordially received at Vienna, and passed a part of the winter there; but the war against the Turks not taking place, he returned by Venice and the Tyrol to Munich, where he arrived in the winter of 1784; and being formally invited by the elector to enter his service, he went to London to ask leave to accept the proposal; and it was granted him, together with the honour of knighthood. On his return to Bavaria, he was made a colonel of cavalry, and aide-de-camp-general to the elector. The first four years of his residence at Munich were principally employed in acquiring information, and in preparing his plans of reform; and in the mean time he continued his physical researches. He made his first experiments on heat in 1786, during a journey to Manheim. In 1785 he was made chamberlain to the elector, and member of the academies of Munich and of Manheim; in 1786 he received from the king of Poland the order of St Stanislas; in 1787 he took a journey to Berlin, and was made a member of the Academy of Sciences of that city; in 1788 he was appointed major-general of the Bavarian cavalry, and privy counsellor of state; and he was placed at the head of the war department, in order to pursue his plans for the improvement of the army.

It was in 1789 that he established the House of Industry at Manheim. He founded also the Military Academy of Munich; he improved the military police of the country; he formed schools of industry for the wives and children of the soldiers; and he embellished the city by a new arrangement of the public gardens. The House of Industry at Munich, which he has described at large in his Essays, was founded in 1790; and from this period may be dated the total abolition of mendicity in Bavaria. His exertions were rewarded by the rank of lieutenant-general of the Bavarian armies, and by a regiment of artillery. In 1791 he was created a count of the holy Roman empire, and obtained the order of the white eagle. His health having suffered from constant application, he obtained permission to take a journey into Switzerland and Italy, and he returned to Bavaria in 1794. He had a severe illness at Naples, and he was not sufficiently recovered, upon his return, to resume his active duties; but he employed himself in writing the first five of his Essays. In 1795, he came to England in order to publish the Essays, and in hopes of exciting the public attention to the importance of attempting a similar reform among the lowest orders in Great Britain. He went to Dublin in 1796, to pay a visit to Lord Pelham, afterwards earl of Chichester, then secretary of state for Ireland; and he was of essential service in the arrangement of several of the public institutions of that country. He was made a member of the Royal Irish Academy, and of the Society for the Encouragement of Arts; and after having left the country, he received the public thanks of the grand jury of the county of Dublin, and of the lord mayor of that city, as well as of the lord lieutenant at the head of the government. Upon his return to London, he superintended some improvements at the Foundling Hospital, and presented several models of machines and implements to the board of agriculture; and he established two prizes, for discoveries relating to heat and light, by placing two sums of L.1000 in the British and in the American funds, to be adjudged biennially, for Europe by the Royal Society of London, and for America by the American Academy of Sciences.

Thompson, Count Rumford.

He was recalled to Bavaria by the exigencies of the moment, which were such as to cause the elector to take refuge in Saxony; General Moreau having advanced with his army to the confines of Bavaria. After the battle of Friedberg, Count Rumford was left in command of the Bavarian army, with instructions to act according to his discretion under the circumstances that might occur; and his firmness was such as to prevent either the Austrians or the French from entering Munich. On the elector's return, he was placed at the head of the department of the general police of Bavaria. His exertions in this office were such as to impair the state of his health, and by way of an honourable retirement, he was sent to London in the capacity of envoy extraordinary and minister plenipotentiary; but being a subject of the king of Britain, he was judged incapable of being received as the diplomatic agent of a foreign court, and he therefore continued to live in England as a private individual. He was very active about this period in projecting and superintending the establishment of the Royal Institution of Great Britain, which was more particularly intended for the application of science to the conveniences and comforts of civil and domestic life, but which has been no less successful in giving opportunity and facility to some of the most refined researches in chemistry and natural philosophy that have distinguished the age, than in serving as a medium for making the treasures of science accessible to the less studious part of the public, and as a model for a variety of other similar undertakings in different parts of the world.

Count Rumford was soon afterwards officially invited to America by the government of the United States, with an offer of an honourable establishment in a public situation; but he considered it as inconsistent with his engagements in Europe to accept the proposal. In the autumn of 1800, when he went to Scotland, a visit of ceremony was paid to him by the magistrates of Edinburgh. He was consulted respecting the abolition of mendicity, and the measures which he recommended were speedily executed with complete success. He was made an honorary member of the Royal Society and of the Royal College of Physicians of Edin-

Thompson, Count Rumford.

urgh; and he received a gold snuff-box as a compliment or his assistance in reforming the culinary establishment f Heriot's Hospital.

After so active and diversified a career, it was not to be xpected that he would be satisfied with the monotony of permanent residence in London. He was so accustomed o labour for the attainment of some object, that when the bject itself was completely within his reach, and the labour was ended, the prospect, which ought to have been niformly bright, became spontaneously clouded, or the erenity even became unenjoyable for want of some clouds o afford a contrast. He had fitted up a small house at rompton, with every contrivance for comfort and convenience that could render it fit for the abode of hospitality nd of luxury; and the arrangements are fully described in he *Bibliothèque Britannique* of his friend Professor Pictet; ut after all he never was known to give a single entertainment in it. The enthusiasm excited by the novelty of ome of his inventions had subsided; and he was even mortified by becoming, in common with the most elevated personages of the country, the object of the impertinent attacks of a popular satirist. It was partly, however, if not tirely, the superiority of the climate of France, that determined him to remove to Paris in the spring of 1802. He ent in the summer to Munich, and the following year he ade a tour in Switzerland and in Bavaria, accompanied y Mademoiselle Lavoisier, whom he married soon after eir return; but their habits were incompatible with matrimonial comfort, and they separated soon after; Count Rumford retiring to Auteuil, about four miles from Paris, here he occupied a house which had formerly belonged to Helvetius and to Cabanis, while his lady continued to live in the metropolis. His latter years were passed almost holly in solitude; he saw only his neighbour Mr Cane-ux, Mr Underwood, and a Mr Parker, an American. He d not even attend the sittings of the Institute, though he had been made one of its eight foreign associates some time before, and always retained a high esteem for its secretary Cuvier, and for some others of its members. His income was abundantly sufficient for his own expenses; for he had obtained from the gratitude of the king of Bavaria a pension of L.1200 a year; and he was allowed by Bonaparte to remain unmolested, though a British subject, when it was found that he had no intercourse with society, amusing himself principally in walking about his garden, and in a solitary game of billiards. In the latter part of his life he had so completely persuaded himself of the great superiority of broad wheels above narrow ones, that he drove about the streets of Paris in a broad-wheeled chariot; and having rediscovered, after Professor Leslie, that black bodies radiate more heat than others, he wore, in the winter, a white hat and a white coat, in order to economize the heat of his person. "These peculiarities, and a peremptory unyielding disposition," says one of his biographers, "were the causes that set him apart from social intercourse, and in all his connexions in life seem to have rendered him less the object of personal attachment than of esteem for his talents and activity." He was about to return to England when he died, on the 21st of August 1814, leaving only one daughter, who afterwards resided in his house at Brompton.

1. Count Rumford's first publication appears to have been the chapter on Marine Artillery which he furnished to alkart's Treatise on Naval Architecture, 1780.

2. New Experiments on Gunpowder, with the Description of an Eprouvette. Phil. Trans. 1781, p. 230. The effect of the powder on the ball was measured by the recoil of the piece, with a correction deduced from the recoil when the piece was empty. It was observed to be sooner heated when fired without ball than with it. The force of the powder is made at least 1300 atmospheres, upon Robins's principles.

3. New Experiments upon Heat. Phil. Trans. 1786, p. 273. These experiments relate principally to the conducting powers of various mediums for heat; but the results are unavoidably complicated with the effects of radiation, in consequence of which a vacuum is supposed to possess a conducting power more than half as great as that of common air.

4. Experiments on the Production of Dephlogisticated Air from Water with various Substances. Phil. Trans. 1787, p. 84. These experiments tend to show that the air obtained by Priestley and Ingenhousz, from plants under water, was derived rather from the water itself than from the substances immersed in it.

5. Experiments made to determine the Positive and Relative Quantities of Moisture absorbed from the Atmosphere by various Substances. P. 240. He finds that wool is more absorbent of moisture than any other substance compared with it; and hence explains the supposed advantage of woollen worn next the skin.

6. Experiments on Heat. Phil. Trans. 1792, p. 48. The author attributes the effect of loose substances in obstructing the passage of heat to their attraction for air, and to their impeding its circulation; and he supposes this to be the only manner in which elastic fluids communicate heat.

7. Account of a Method of Measuring the Comparative Intensity of Light emitted by Luminous Bodies. Phil. Trans. 1794, p. 67.

8. Letter announcing a Donation for a Prize Medal. Phil. Trans. 1797, p. 215.

9. Experiments to determine the Force of Fired Gunpowder. P. 272. This force he supposes to amount to between 20,000 and 50,000 atmospheres, instead of 10,000, as Bernoulli computed it; but he makes a great mistake in supposing that the whole of the water which can possibly be contained in the gunpowder would be sufficient to furnish as much steam as would be required, since steam, under a pressure of 20,000 atmospheres, must be considerably more dense than water itself.

10. Inquiry concerning the Source of the Heat excited by Friction. Phil. Trans. 1798, p. 80. The capacity of the chips of iron afforded by friction in boring a cannon, was found not to differ from that of the iron in its original state: hence it is inferred that the heat could not have been furnished by them, and that it must probably have been generated. Mr Haldalt afterwards repeated the experiment under circumstances still more decisive; and Sir Humphry Davy showed that two pieces of ice rubbed together, in a room below the freezing temperature, would melt each other.

11. Inquiry concerning the Chemical Properties that have been attributed to Light. P. 449. He attributes these properties to the effect of an intense heat confined to a small space; but the latter experiments on the chemical effects of the spectrum are sufficient to supersede this opinion.

13. An Account of a Curious Phenomenon observed on the Glaciers of Chamouny, with some Observations on the Propagation of Heat in Fluids. Phil. Trans. 1804, p. 23. An effect depending on the expansion of water in cooling near the freezing point.

14. Concerning the Nature of Heat, and the Mode of its Communication. P. 77. He conjectures that cold is a positive quality, capable of being propagated by radiation.

Several of these memoirs were reprinted under the title of Philosophical Papers, vol. i. Lond. 1802, 8vo.

15. The Essays constitute four volumes 8vo. Lond. 1795–1800. Reprinted 1800. In French, 2 v. 8. Genev. 1799. Recueil de Rapports... sur les Soupes. Par. 1801. They are eighteen in number. i. Account of an Establishment for the Poor at Munich. In Ital. 8. Venice, 1798. ii. On Establishments for the Poor in general. iii.

Of Food, and of Feeding the Poor. iv. Of Chimney Fire-places. v. Account of several Public Institutions formed in Bavaria. vi. On the Management of Fire, and the Economy of Fuel. vii. On the Propagation of Heat in Fluids, extending to Liquids the doctrine which he had before advanced respecting Elastic Fluids. viii. On the Propagation of Heat in various Substances. Phil. Trans. ix. Experimental Inquiry concerning the Source of Heat excited by Friction. x. On Kitchen Fire-places and Kitchen Utensils. xi. On Chimney Fire-places. xii. On the Salubrity of Warm Rooms in Cold Weather. xiii. On the Salubrity of Bathing, and the Construction of Warm Baths. xiv. Supplementary Observations on the Management of Fires. xv. On the Use of Steam for Transporting Heat. xvi. On the Management of Light in Illumination, with an Account of a new Portable Lamp. xvii. On the Source of the Light manifested in the Combustion of Inflammable Bodies. xviii. On the excellent Qualities of Coffee, and the Art of making it in Perfection.

16. There are several little papers on Steam Kitchens, on the Strength of Soft Materials, and on some other similar subjects, in the first numbers of the Journals of the Royal Institution. 8. Lond. 1800.

17. The series of investigations relating to Heat and Light, which Count Rumford began to communicate to the Royal Society, were continued, and rather more fully detailed, in several of the volumes of the Memoirs of the Institute, Mathematical Class; into which they were of course admitted as the productions of a foreign associate. The first of these is in the sixth volume. 4. Par. 1806, p. 71, containing a Description of a new Instrument; a Thermoscope, or a Differential Thermometer, resembling that of Leslie. (18.) The second, p. 74. Researches on Heat; showing the Effect of the Difference of Surface on Radiation. (19.) iii. P. 88. Further Experiments; on the Effect of blackening the Surface. (20.) iv. P. 97. Researches continued; on the different Properties of Bodies with respect to Radiation, and to Conducting Power. (21.) v. P. 106. Further Researches; some good Experiments on the Passage of Heat through Solids. (22.) vi. P. 123. Experiments on the Heat of the Solar Rays; which was found not to be affected by their convergence or divergence, or by their having met in a focus and crossed each other. (23.) vii. Vol. vii. i. 1806, p. 78. Remarks on the Temperature of Water at the Maximum of Density; making it 41° of Fahrenheit, or 5° centigrade. Phil. Trans. 1804. (24.) viii. Vol. viii. i. 1807, p. 223. On the Dispersion of the Light of Lamps by Screens of Ground Glass, Silk, and so forth, with a Description of a new Lamp. (25.) ix. P. 249. On the Cooling of Liquids in Vases of Porcelain, gilt and not gilt; showing the utility of gilding them externally, with some good reasoning on the nature of heat.

26. He was latterly engaged in composing a work on the Nature and Effects of Order, which he never completed, although no person was better qualified to write on the subject.

Count Rumford certainly possessed considerable facility of invention, and there was a very laudable spirit of originality in his views and modes of reasoning, although he had never leisure to acquire profound learning in any department of study. "In person he was above the middle size, with a dignified and pleasing expression of countenance, and a mildness in his manner and his tone of voice. He was ambitious of fame and distinction, and had too great a propensity to dictate," without sufficiently regarding the opinions of others who were of equal authority with himself. His mode of life was abstemious, and his health was even supposed to have suffered from too great abstinence, though his regimen was much more the result of medical opinions respecting his health, than of his own peculiar taste for temperance.[1] (L. L.)

THOMSON, James, a poet of great eminence, was born in the parish of Ednam and county of Roxburgh, on the 11th of September 1700. His father was minister of that parish, which is contiguous to Kelso. The maiden name of his mother was Beatrix Trotter, and she was co-heiress of a small demesne in the county. In Dr Johnson's life of the poet she is called Hume; a mistake which is pointed out by Boswell, who supplied the great biographer with some materials for his narrative, which he either forgot or neglected. Mrs Thomson presented her husband with nine children, whose maintenance and education may have been a pleasing, but could not be a light burden, to parents circumstanced as they were. At an early age James showed great aptitude for learning; and Mr Ricearton,[2] a neighbouring clergyman, furnished him with books, and took upon himself the chief direction of his studies. The elementary branches of knowledge Thomson acquired at Jedburgh school. There he was inoculated with the love of versifying; but how his thoughts were directed into that channel, does not appear. Mediocrity is easily satisfied with its own attainments, and cherishes its mean performances with pious care. After the first gaze of parental fondness, the *mens divinior* turns from its offspring with indifference or aversion, and endeavours to breathe life into a more perfect progeny. On the first day of every year, Thomson committed to the flames all the poetical effusions of the preceding twelvemonth. The master could perceive in his pupil no indications of superior capacity; but schoolmasters are not unfrequently the most fallible of all prophets. One youth, who was to enter upon a career of glory, often dwindles into insignificance; and another, who has been consigned to perpetual obscurity, as often covers his oracular preceptor with confusion by arriving at distinction.

From Jedburgh school Thomson was removed to the university of Edinburgh. After he had prosecuted his studies there for two years, he received a hasty summons to attend his father in his last extremity, but did not arrive in time to receive his dying benediction. His mother now removed with her family to Edinburgh; and in order to carry this arrangement into effect, it became necessary for her to raise money by the mortgage of her little estate. Although somewhat of an enthusiast in religious matters, she conducted her domestic affairs with great prudence and economy, and lived to see her son distinguished by the favour of the great. The friends of Thomson were desirous that he should direct his views towards the church; but he does not appear to have had any great predilection for the clerical profession. At college he remained unnoticed, until Mr Hamilton, the professor of divinity, bestowed a mixture of praise and censure upon a probationary exercise of his, explanatory of one of the psalms. The professor commended the fervour of his sentiments and the majesty of his diction; but added, that if he wished to be of any use as a preacher of the gospel, he must descend to the level of vulgar understandings. Whether the commendation was cold, and the reproof warm, or whether Thomson had anticipated unqualified applause, and was disgusted by the modification with which it was administered, he now abandoned all thoughts of continuing his theological studies. His discourse had been censured as too poetical; and the poems which he handed about at this time were condemned by some small critics of the city, upon what ground it is unnecessary to inquire. That his youthful productions were not without their faults, it is very easy to conceive, and these were pointed out with laborious minuteness; but their beauties, of which it is improbable that they were entirely destitute, passed unobserved. Finding that his countrymen had formed a standard of composition, both in prose and verse, which he was unable to reach, Thomson resolved to submit his productions to a tribunal of strangers. But although the former were insensible to his merits when their favour might have been of some use to him, they did not fail to praise him when their praise was of little value; nor did they neglect the accustomed tribute of lamentation when all tears were vain. Long after the tomb had closed over his remains, a society of gentlemen in the Scottish metropolis was formed for the purpose of celebrating his birth-day by a musical entertainment. These tuneful associates, who continued their union for several years, were pleased to call themselves the Knights Companions of the Cape.

---

[1] Pictet, Bibliothèque Britannique. Baldwin's Literary Journal. Gentleman's Magazine, vol. lxxxiv. Aikin's General Biography, vol. x. Chalmers's Biographical Dictionary, vol. xxix.

[2] So the name is given by Dr Murdoch; but it may perhaps be doubted whether this was not the same individual whose works were published under the following title: "The Works of the late Reverend Mr Robert Riccaltoun, Minister of the Gospel at Hobkirk." Edinb. 1771–2, 3 vols. 8vo. The parishes of Hobkirk and Ednam are within a very moderate distance of each other.

Thomson now repaired to London, carrying with him letters of recommendation to various individuals of influence; but of these credentials he had the misfortune to be robbed. They were tied up in a handkerchief, and when he was staring at the wonders of the metropolis, he was eased of his bundle by a pickpocket, who was probably as much chagrined by what he had gained, as Thomson was by what he had lost. To London it is said that he was allured by the hopes excited in him by Lady Grizzel Baillie, who promised much, and performed nothing. For the supply of his numerous wants, and among others that of a pair of shoes, his sole dependence was upon his poem of Winter, which the booksellers manifested little eagerness to purchase. At last he sold it for a trifling sum, but it was long in finding admirers, and the publisher, "J. Millan, at Locke's Head in Shug-Lane," had some misgivings that his parsimony savoured of rashness. It however fell in the way of some persons of taste and discernment, who spread its fame, and it was finally received with very general applause. It appeared in 1726, with a prose dedication to Sir Spencer Compton.[1] At this period of his history, the indigent bard was much indebted to the friendship of Mallet, who was then tutor to the sons of the duke of Montrose. Mallet was a man of consummate dexterity, and very well qualified to enlighten his countryman in the art of pushing his fortune. In his zeal for the dignity of letters, Dr Johnson remarks that Thomson at this time "obtained the notice of Aaron Hill, whom, being friendless and indigent, and glad of kindness, he courted with every expression of servile adulation." Hyperbolical encomium can expect little sympathy from those who have never been obliged, any more than raving resentment from those who have never been injured; but surely the eloquence of gratitude is not so frequently heard as to create disgust. It appears from the interchange of high-flown compliments in the correspondence between Hill and Richardson, that flattery seldom came amiss to either; yet Hill was an ingenious and benevolent man, upon whom much praise could be conscientiously bestowed. He was also a man of spirit, as Pope had occasion to ascertain, when he provided him with a niche in the Dunciad. A proof of all these qualities now appeared in his conduct to the young poet. Of the dedication Sir Spencer Compton took no notice, until there appeared in the newspapers a copy of complimentary verses, addressed by Hill to Thomson, lamenting the miseries of genius, and condemning the paltry Maecenases of the age. The result of this memento was an interview with Thomson, in which Sir Spencer, with much of the grace and delicacy of one bestowing alms upon a mendicant, made the poet a present of twenty guineas. The successful author of the present day has reason to be thankful that the multiplicity of readers has placed him above dependence upon any other patronage, whether private or political. A second impression of *Winter* was now called for, and the author's friends began rapidly to increase. Among these was Dr Rundle, afterwards bishop of Derry, who introduced him to the Lord Chancellor Talbot. In 1727 appeared *Summer*, which was followed by "A Poem sacred to the Memory of Sir Isaac Newton." To this production he was enabled, by the instruction of his friend Mr Gray, to impart a philosophic spirit, worthy of the departed sage. This year also produced *Britannia*, in which was echoed the general cry against the ministry for remissness in vindicating the national honour, which had been insulted by the maritime depredations of the Spaniards. In 1728 was published *Spring*, dedicated to the countess of Hertford, afterwards duchess of Somerset, by whom the poet was invited to pass some time at the family-seat. The countess was herself addicted to the muses, and regaled her visitor by reciting to him many of her poetical lucubrations. This species of pastime, however, Thomson found somewhat insipid, and sought relief so frequently in the jovial company which surrounded his lordship's table, that he forfeited the favour of his learned hostess, and this invitation to become her guest, which was the first, was also the last that he ever received. In 1729, the tragedy of Sophonisba was acted at Drury Lane; and in the following year, by the addition of *Autumn*, the plan of "The Seasons" was completed, and they were combined in a quarto volume. The success of the play was much more moderate than was anticipated by the author's numerous and powerful friends. The feeble verse,

> O, Sophonisba, Sophonisba, O!

and the parody to which it gave rise,

> O, Jemmy Thomson, Jemmy Thomson, O!

are still remembered; a fate which has attended few of his other tragic lines. His genius does not seem to have been dramatic: he is often flat, and when he rises, he seldom rises above rant; even his declamation, into which his dialogue too often degenerates, is not splendid, and his pathos is not affecting. In this, and in all his other plays, there is a perpetual repetition of the word glory, which argues great poverty of sentiment; and Hurd did him little injustice when he applied to his palpable and laborious art in tragedy the words of Horace, *promissus grandia turget.* Nor does he display any skill in depicting character, being a more diligent observer of external nature, than of the qualities of men. His heroine hates the Romans, and, with little variation of expression, she says so every time she appears upon the scene. Syphax is only another Bajazet, and his rival Masinissa a common tragic lover, with whose raptures and lamentations no one has much sympathy.

About this time, Thomson is said to have been under great obligations to the eccentric generosity of Quin, the celebrated actor, who, as the story goes, relieved him from a spunging-house in Holborn. After the publication of his Seasons, one of his creditors had him arrested, judging that a likely time to procure payment. The amount of the debt was not forthcoming, and Thomson had every prospect of a lengthened sojourn in his involuntary retirement, when he was visited by Quin, with whom he had no personal acquaintance. The comedian gracefully apologized for his intrusion, to which Thomson was easily reconciled. The additional liberty of ordering supper was also taken in good part. After they had supped luxuriously and drunk freely, Quin informed his new associate that he was indebted to him in the sum of one hundred pounds for pleasure received in the perusal of the Seasons. He then deposited the money on the table, and took his departure, leaving the imprisoned bard full of gratitude and amazement.

---

[1] Winter; a Poem. By James Thomson, A. M. Lond. 1726, fol.

Thomson's poetical labours were now agreeably interrupted by an invitation to attend the eldest son of Lord Talbot upon his travels. For this advantageous opportunity of extending his experience, he was indebted to the friendship of Dr Rundle. Upon his return to England, he was made secretary of briefs; the profits of which appointment were fully adequate to all his wants and desires. When in Italy, he conceived the idea of writing the poem of *Liberty*, which was afterwards completed in five parts, successively published in quarto; the first, second, and third in 1735, the fourth and fifth in 1736. This poem he dedicated to the prince of Wales. One who has read the achievements of the masters of the world, and seen their posterity sunk in slavery and vice, is apt to imagine that he can say something that is new on the blessings of freedom and the horrors of oppression. But his sensations, which have been felt by all, have been described by many; and in the fervour of composition, mistaking the children of memory for the offspring of fancy, a great writer may produce, upon such an impracticable theme, nothing but a tissue of common-places, when he dreams that he has been making an invaluable addition to the treasures of knowledge. No man, whether sane or otherwise, prefers darkness and chains to light and the free range of creation; and when Thomson proved, by a multiplicity of examples drawn from the history of every age and nation, that the former were to be shunned and the latter pursued, the reader was neither amused nor instructed. By a species of infatuation not uncommon among authors, Thomson considered this poem the best of all his productions. It was coldly received by the public when it first appeared; and after the poet's death, when Sir George Lyttelton was collecting his works for the press, he thought the best way of consulting the reputation of his deceased friend was to abridge it; a strange and unwarrantable proceeding, which no motives can justify. In the mutilated condition to which it was reduced by Lyttelton, it now appears.

The mortification of finding the public opinion of his poem opposed to his own, was followed by the death of Lord Talbot, an event which deprived Thomson of his place. The new chancellor, Lord Hardwicke, kept it vacant for some time, in order to afford him an opportunity of applying, in the usual form, to be reinstated; but no such application was made, and his lordship bestowed it upon another person. The silence of Thomson probably proceeded from an incurable habit of neglecting his own affairs; for his experience was sufficient to inform him, that the dignity of a needy man who expects to be loaded with unsolicited benefits, will soon be his sole possession. His great friends, however, did not desert him; and soon after he had ceased to be a placeman, he was introduced to the prince of Wales, who, among other modes of courting popularity, professed himself a friend to men of letters. Being questioned by the prince on the state of his affairs, Thomson informed his royal highness that "they were in a more poetical posture than formerly." This gay reply produced what might have been denied to a tedious catalogue of grievances, a pension of one hundred pounds a year. This allowance, well-timed as it was, being insufficient to support him in his former mode of living, he again had recourse to his pen. In 1738 his tragedy of Agamemnon was acted at Drury Lane. The performance was graced by the presence of Pope, who, on his entering the theatre, received from the audience nearly all the applause of the evening; for although supported by the acting of Quin in the hero, the play, to use the words of Johnson, "had the fate which commonly attends mythological stories, and was only endured, but not favoured." Being still compelled to write for the stage, Thomson next produced Edward and Eleanora, to the first edition of which is prefixed the following advertisement: "The representation of this tragedy on the stage was prohibited in the year one thousand seven hundred and thirty-nine." Brooke's Gustavus Vasa was the first, and Thomson's the second, play prohibited by the operation of the new act for licensing dramatic performances. In both cases this act seems to have been exercised with very superfluous rigour. The following lines, however, which occur near the beginning of Thomson's tragedy, may perhaps have arrested the eye of authority, and sealed its fate.

> In times like these,
> Disturb'd and low'ring with unsettled freedom,
> One step to lawless power, one old attempt
> Renew'd, the least infringement of our charters,
> Would hurl the giddy nation into tempest.

In conjunction with Mallet, he afterwards wrote the masque of Alfred, which was played before the prince of Wales. To the favour of that illustrious personage, who was on bad terms with the court, it is probable that he owed, in some degree, the prohibition of his former drama. The tragedy of Tancred and Sigismunda, taken from the novel in Gil Blas, was performed at Drury Lane in 1745. It was the most successful of his dramatic efforts, and kept possession of the stage until a recent period. This tragedy was followed by the Castle of Indolence, the last of his works that was published in his life-time, and, in the opinion of many, the most brilliant effort of his genius. The frequent recurrence of the rhyme in the Spenserian measure occasionally produces a redundance both of sentiment and expression; but this objection scarcely applies to any one stanza of the first canto of this poem. Every line breathes the spirit of seductive languor, to which every new image lends additional force, until the mind is steeped in luxurious lethargy. In the second canto the obvious reasoning of Sir Industry is a feeble antidote to the eloquent sophistry of the wizard Indolence in the first. The necessity for further literary exertion was removed by his appointment to the office of surveyor-general of the Leeward Islands, which was procured for him by the influence of Lyttelton. His clear emoluments amounted to about three hundred pounds a year, and the duties of his office he was suffered to perform by deputy.[1]

Thomson had now every prospect of enjoying many years of learned ease; but he had scarcely ceased to be the sport of fortune, when he was suddenly removed from the scene. A cold caught upon the river between London and Kew, was succeeded by a fever, of which he had partly recovered, when imprudent exposure to the evening dews induced a recurrence of his malady, and terminated his life on the 27th of August 1748. His remains were interred in the church of Richmond in Surrey; and in 1762 a monument was erected to his memory in Westminster Abbey. The expense of this memorial was defrayed by an edition of his works, published during that year, in two volumes quarto. The king subscribed one hundred pounds. A life of the author was prefixed by his intimate friend Dr Murdoch. But the noblest tribute to the memory of Thomson is the beautiful ode of Collins, beginning,

> In yonder grave a Druid lies,
> Where slowly winds the stealing wave;
> The year's best sweets shall duteous rise
> To deck its poet's sylvan grave.

---

[1] His friend Paterson, the author of the tragedy of Arminius, which was prohibited by the Lord Chamberlain soon after Edward and Eleanora had met a similar fate, was Thomson's deputy, and lived to succeed him in his office.

The tragedy of Coriolanus, which he had prepared for the stage, was after his death performed at Covent Garden. The profits of the representation discharged his debts, and left a considerable overplus, which was remitted to his sisters. The principal character was supported by Quin, who also delivered a prologue written by Lyttelton. When he had to utter the following lines, the great comedian, who had long lived on terms of the most affectionate intimacy with Thomson, was entirely overcome by his emotions:

> He lov'd his friends—forgive this gushing tear—
> Alas! I feel I am no actor here.

Thomson was a man of a gross habit of body, and of a dull aspect. In a mixed or numerous company he was ill at ease, and appeared to disadvantage; but when surrounded by a few familiar faces, his embarrassment disappeared, and he became frank, cheerful, and amusing. As a son and brother, his conduct was exemplary. A letter to his sister, inserted in Johnson's narrative, breathes the purest spirit of fraternal affection. He was warmly attached to his friends, whom he inspired with the same degree of cordial tenderness. He was not easily roused to personal exertion, either in his own behalf or that of others; but his money was freely shared with those whom he loved or pitied. In his prosperous days, he was never known to shake off a humble friend; and even Savage, the most inconvenient of all associates, whose pride, although he lived by borrowing, was as sensitive as an unhealed wound, praised Thomson's steady friendship to the skies. Upon the same authority, as related by Johnson, we learn that his habits of life formed rather a ludicrous contrast to the delicacy of sentiment which pervades his writings. The veracity of Savage was not his most shining quality, but if Thomson had the failings imputed to him, he had also the grace to be ashamed of them; an example which might have been followed with advantage by succeeding writers, who have endeavoured to earn money and applause by making the world a confidant of their vices.

From Thomson, as an author, has never been withheld the highest praise, that of originality. "He thinks," says Johnson, "in a peculiar train, and he thinks always as a man of genius; he looks round on nature and life with the eye which nature bestows only on a poet; the eye that distinguishes, in every thing presented to its view, whatever there is on which imagination can delight to be detained, and with a mind that at once comprehends the vast, and attends to the minute. The reader of the Seasons wonders that he never saw before what Thomson shows him, and that he never yet has felt what Thomson impresses." Where intellectual eminence was not conspicuous, Johnson distributed commendation with a very sparing hand, whether the character reviewed was dignified by rank, which he valued much, or by virtue, which he valued more. Upon a lover of liberty, a man of easy morals, and a writer of blank verse, in his estimation a delinquent almost as odious as either, he would have bestowed no praise that he could conscientiously have withheld. This liberal encomium on Thomson, therefore, ought to satisfy the warmest admirers of that poet, and to silence those who would detract from his reputation.

The Seasons have been translated into several languages. A translation into Latin verse was published by Brownell. There are three different versions into French prose; and a version into French verse was published by J. Poullin in the year 1802. Of Spring and Winter a Danish version was executed by Peter Foersom, and was printed in the posthumous collection of his poems.[1]

THOR, the eldest and bravest of the sons of Odin and Frea, was, after his parents, the greatest god of the Saxons and Danes while they continued heathens. They believed that Thor reigned over all the aerial regions, which composed his immense palace, consisting of 540 halls; that he launched the thunder, pointed the lightning, and directed the meteors, winds, and storms. To him they addressed their prayers for favourable winds, refreshing rains, and fruitful seasons; and to him the fifth day of the week, which still bears his name, was consecrated.

THORDA, or THORENBURG, a district of the province of Suabenburgen, in the Austrian kingdom of Hungary. It is a long narrow district, extending nearly the length of the whole province. It covers nearly 2000 square miles, but scarcely contains more than 70,000 inhabitants, the northern part comprising a great portion of the sterile Carpathian Mountains; but the southern part produces good corn, wine, and fruits, and rears some large flocks of sheep. The capital is a town of the same name, on the river Aranyos, which divides it into the old and new town. It contains two Catholic and two Calvinist churches, a Lutheran, a Greek, and a Unitarian church, and 7100 inhabitants. The Unitarians have a college, and the Franciscan monks a monastery. Near Thorda there are some mines of rock-salt, yielding 25,000 tons of culinary salt annually. Long. 23. 42. 12. E. Lat. 46. 31. 53. N.

THORN, a city, formerly one of the most distinguished, in the kingdom of Poland, but now the capital of a circle of the same name in the government of Dantzig and the province of West Prussia. It stands on the river Vistula, which is there nearly two miles across. There is a bridge of boats from the city to an island in the centre of the stream, and another from that island to the right bank. Thorn is a frontier town towards the Russian territory, is strongly fortified on every side, and a large garrison is always quartered in it. The buildings are of an antique fashion, very large and firm. There is a good market-place, but the streets are crooked and narrow. It contains three Catholic, one Lutheran, and one Reformed church; a monastery, a nunnery, a Catholic gymnasium with a good library, 800 houses, and 10,400 inhabitants, who carry on trade on the river in corn, and make woollens, linens, leather, paper, soap, and gloves. It was the birth-place of the celebrated astronomer Copernicus, born in 1515. Long. 23. 44. 57. E. Lat. 53. 1. 30. N.

THORNBURY, a town of the hundred of the same name in the county of Gloucester, 124 miles from London. It is situated on a small stream that falls into the Severn, and consists of one street about half a mile long, with a large church resembling a cathedral, and the remains of a magnificent palace, begun, but never finished, by the duke of Buckingham in 1511. Thornbury is an ancient borough, and has a market on Saturday. The inhabitants amounted in 1821 to 2764, and in 1831 to 4375.

THORNE, a town of the hundred of Strafforth and Tickhill, in the west riding of the county of York, 167 miles from London. It is situated in a marshy district, being surrounded by the rivers Don, Ouse, and Aire, and being near the canal of Headley. It has little trade except that of ship-building, which of late has declined. There is a market on Wednesday. The inhabitants amounted in 1821 to 3463, and in 1831 to 3779.

THORNHILL, SIR JAMES, an eminent English painter, was born in Dorsetshire in 1676, of an ancient family, but was constrained to apply to some profession by the distresses of his father, who had been reduced to the necessity of selling his family estate. His inclination directed him to the art of painting; and on his arrival at London he applied to his uncle, the famous Dr Sydenham, who enabled him to proceed in the study of the art under the direction of a painter who was not very eminent. The genius of Thornhill, however, made ample amends for the insufficiency of his instructor; and by a happy application of his talents he made so great a progress, that he gradually rose to the highest reputation. His genius was well adapted to historical and allegorical compositions; he possessed a fertile and fine invention; and he sketched his thoughts with great ease, freedom, and spirit. He equally excelled in portrait, perspective, and architecture; showed an excellent taste for design, and had a free and firm pencil. He was so eminent in many parts of his profession, that he must ever be ranked among the best painters of his time; and his performances in the dome of St Paul's church at London, in the hospital at Greenwich, and at Hampton Court, are such public proofs of his merit as will convey his name to posterity with honour. This painter lived in general esteem: he enriched himself by the excellence of his works; was appointed state-painter to Queen Anne, from whom he received the honour of knighthood; had the singular satisfaction to repurchase his family estate; and was of sufficient importance to be elected a member of parliament. He died in 1732.

---

[1] Digte af Peter Foersom, kongelig Skuespiller: udgivne efter hans Död. Kiöbenhavn, 1818, 8vo. It may not be superfluous to mention, that a beautiful edition of the Seasons was printed by Bodoni: "The Seasons. By James Thomson." Parma, 1794, 4to. It is dedicated "To David Steuart, Esquire of Cardneys, late Lord Provost of the City of Edinburg."

Thornhill, a large and thriving village in the parish of Morton and county of Dumfries, is delightfully situated in a vale through which runs the river Nith. It consists of a few streets, having in the centre a cross, erected by the last duke of Queensberry. It has of late been much improved by the proprietor, the present duke of Buccleuch, who has had the streets levelled and paved, common sewers formed, and a good supply of water brought in. It contains two dissenting places of worship. It possesses also a branch of one of the Edinburgh banks, and a subscription library established in 1814. In 1831 the population amounted to 1373.

THOROUGH BASS (Ital. *Basso Continuo*). See Music. From an edition of Emilio del Cavaliere's musical drama, called *La Rappresentazione di Anima e di Corpo*, published by Guidotti in 1600 at Bologna, it appears that Cavaliere was one of the earliest musicians who conceived the idea of writing an instrumental bass different from the vocal bass, gave it the name of *basso continuo*, and accompanied it by numerals and signs intended to direct the instrumental performers in the improvised accompaniments which they executed. "This fact," says an eminent continental writer, "is proved by the instructions which Guidotti has given in that edition regarding those numerals and signs. *I numeri piccoli posti sopra le note del basso continuato per suonare*, says Guidotti, *significano la consonanza e la dissonanza di tal numero, come il* 3 *terza, il* 4 *quarta, e cosè di mano in mano*." Thus it would seem that G. Sabbatini, who, in his work printed at Venice in 1628, claims the invention of *figured bass*, must yield the priority at least to Cavaliere. It appears however that G. Sabbatini was the first person who published the precepts of the so-called Rule of the Octave. Andrea Majer of Venice, in his *Discorso sulla Origine, Progressi, e Stato attuale della Musica Italiana*, says, that in the *Euridice* and Madrigals of Caccini, and other compositions of the sixteenth century, we find a *basso continuo*. But this does not overturn L. Viadana's claim, set forth as about 1597, in his *Cento Concerti*, published in 1603; since the *Euridice* was set to music by Perti and Caccini, and also performed in 1600; while Caccini's *Euridice*, set to music entirely by himself, and also his Madrigals, were first published in 1615. See Music, sect. *Harmony*.

THOROUT, a market-town of the Netherlands, in the province of West Flanders and arrondissement of Bruges. It is on the chaussée leading from Menen to Bruges, and contains 5160 inhabitants.

THORVERTON, a decayed town of the county of Devon and the hundred of Hayridge, 175 miles from London. In former years the principal occupation of the inhabitants was making serges and other coarse woollen goods for the Spanish market, and long ells for the East India Company; but both these branches have diminished by the competition of the north-country manufacturers. The population amounted in 1821 to 1317, and in 1831 to 1455.

THOTH, or Theut (called by the Phœnicians *Taaut*, by the Greeks *Hermes*, and by the Romans *Mercury*), was a Phœnician of very superior talents, and one of the civilizers of mankind. He was prime minister to Osiris, whom, after his death, he deified; and he was himself deified by his countrymen the Egyptians, for the benefits which he had rendered to the human race.

THRACE, a country very frequently mentioned by the Greek and Latin writers, deriving its name, according to Josephus, from Tiras, one of the sons of Japhet. It was bounded on the north by Mount Hæmus; on the south by the Ægean Sea; on the west by Macedon and the river Strymon; and on the east by the Euxine Sea, the Hellespont, and the Propontis. The Thracian Chersonesus is a peninsula enclosed on the south by the Ægean Sea, on the west by the gulf of Melas, and on the east by the Hellespont; being joined on the north to the continent by a neck of land about thirty-seven furlongs broad. The inland parts of Thrace are very cold and barren, the snow lying on the mountains the greater part of the year; but the maritime provinces are productive of all sorts of grain and necessaries for life, and withal so pleasant, that Mela compares them to the most fruitful and agreeable countries of Asia.

The ancient Thracians were deemed a brave and warlike nation, but of a cruel and savage temper; being, according to the Greek writers, strangers to all humanity and good nature. It was to the Thracians, however, that the Greeks were chiefly indebted for the polite arts that flourished among them; for Orpheus, Linus, Musæus, Thamyris, and Eumolpus, all Thracians, were the first, as Eustathius informs us, who charmed the inhabitants of Greece with their eloquence and melody, and persuaded them to exchange their fierceness for a sociable life and peaceful manners; nay, great part of Greece was anciently peopled by Thracians. Tereus, a Thracian, governed at Daulis in Phocis, where the tragical story of Philomela and Progne was acted. From thence a body of Thracians passed over to Eubœa, and possessed themselves of that island. Of the same nation were the Aones, Tembices, and Hyanthians, who made themselves masters of Bœotia; and great part of Attica itself was inhabited by Thracians, under the command of the celebrated Eumolpus. Thrace was anciently divided into a number of petty states, which were first subdued by Philip of Macedon. On the decline of the Macedonian empire, it fell under the power of the Romans, and continued under subjection to them till the irruption of the Turks.

THRAPSTON, a town in the hundred of Navisford and county of Northampton, seventy-five miles from London. It is built on the river Nen, by which it has some trade with Lynn and with Northampton. There is a market on Tuesday. The inhabitants amounted in 1821 to 854, and in 1831 to 1014.

THRASHING, in *Agriculture*, the operation by which corn is separated from the straw. This operation is performed in a variety of ways, sometimes by the feet of animals, sometimes by a flail, and sometimes by a machine called a *thrashing mill*. See the article Agriculture.

THREE Hills Island, one of the Hebrides, in the South Pacific Ocean, about twelve miles in circumference. Long. 168. 35. E. Lat. 17. 7. S.

Three Hummock Island, a small island on the east coast of New Holland; also an island on the north coast of Van Diemen's Land. Long. 145. E. Lat. 40. 45. S.

Three Islands, small islands in the Eastern Seas, near the east coast of Bintang. Long. 105. 2. E. Lat. 1. 10. S.

Three Kings, three small islands in the South Pacific Ocean, near the north coast of New Zealand. Long. 172. 12. E. Lat. 34. 13. S.

Three Points Cape, the north head of the entrance into Broken Bay, on the east coast of New Holland. Long. 151. 23½. E. Lat. 33. 32½. S.

Three Rivers, the name of numerous small islands, about eight in number, scattered over the Eastern Seas, two on the coast of Celebes, one on the coast of Amboyna, and one on the coast of Madagascar.

THRONE, a royal seat or chair of state, enriched with ornaments of architecture and sculpture, raised on one or more steps, and covered with a kind of canopy. Such are thrones in the rooms of audience of kings and other sovereigns.

THUANUS, Jacobus Augustus, an historian of great and merited reputation, is better known by this classical, than by his vernacular name of *Jacques Auguste de Thou.* He was the son of Christophe de Thou, first president of the parliament, and was born at Paris on the 8th of October 1553. He received a very learned education, and became distinguished among men of learning. The highest preferment which he obtained was that of president *à mortier* in the parliament of Paris. He died on the 7th of May 1617, leaving behind him the character of one of the most excellent men of his age and nation. Besides Latin poems, and an account of his own life written in the same language, he composed a very ample and valuable work, entitled *Historia sui Temporis.* It is indeed a work unparalleled in modern literature. The first eighteen books were published at Paris in 1604; and the author continued to make various additions till the year 1609, when he completed the printing of eighty books. The fearless liberality of his sentiments had excited so violent a clamour against him, that he did not venture to publish the more recent portion of his history. To his faithful friends Du Puy and Rigault he left a copy of his entire history prepared for the press; and as they found it could not be safely printed at Paris, they sent it to Geneva, where the edition was superintended by Lingelsheim. For the sake of greater concealment, the imprint of Lyon was substituted for that of Geneva; and the editor added a preface, stating that he had in vain waited for an edition of Thuanus's history from the hands of his executors, and therefore determined to publish it from a copy which had been transmitted to him from the author. Under these circumstances, the work, complete in one hundred and thirty-eight books, was first published in the year 1620, together with the six books of the author's memoirs of his own life. Other two impressions proceeded from Frankfurt and Geneva; but all these have been superseded by the splendid and valuable edition published at London by Samuel Buckley, in seven volumes folio, in the year 1733.[1]

THUCYDIDES, a celebrated Greek historian, was born at Athens, 471 B. C. He was the son of Olorus, and grandson of Miltiades, who is thought to have been descended from Miltiades the famous Athenian general, and to have married the king of Thrace's daughter. He was educated in a manner suitable to his quality, that is, in the study of philosophy and eloquence. His master in the former was Anaxagoras, in the latter Antiphon; one, by his description in the eighth book of his history, for power of speech almost a miracle, and feared by the people on that account. Suidas and Photius relate, that when Herodotus recited his history in public, a fashion in use then and many ages after, Thucydides felt so great a sting of emulation, that it drew tears from him; insomuch that Herodotus himself took notice of it, and congratulated his father on having a son who showed so wonderful an affection to the Muses. Herodotus was then about twenty-nine years of age, Thucydides about sixteen.

Thucydides.

When the Peloponnesian war was impending, he conjectured truly that it would prove a subject worthy of his labour; and it no sooner commenced than he began to keep a journal. This explains the reason why he has attended more to chronological order than to unity of design. During the same war he was commissioned by his countrymen to relieve Amphipolis; but the quick march of Brasidas the Lacedæmonian general defeated his operations, and Thucydides, unsuccessful in his expedition, was banished from Athens. He withdrew to Scaptesula, a town of Thrace, from whence he had obtained a rich wife. His exile commenced in the eighth year of this celebrated war; and in the place of his banishment the general began to write an impartial history of the important events which had happened during his administration, and which still continued to agitate the several states of Greece. This famous history is continued only to the twenty-first year of the war; and the remaining part of the time till the demolition of the walls of Athens was described by the pen of Theopompus and Xenophon. He spared neither time nor money to procure authentic materials; and the Athenians, as well as their enemies, furnished him with many valuable communications, which contributed to throw great light on the different transactions of the war. His history has been divided into eight books, the last of which is imperfect, and is supposed to have been written by his daughter.

The historian of Halicarnassus has often been compared with the son of Olorus, but each has his peculiar excellence. Sweetness of style, grace and elegance of expression, may be called the characteristics of the former; while Thucydides stands unequalled for the fire of his descriptions, the conciseness, and at the same time the strong and energetic manner, of his narratives. His relations are authentic, as he himself was interested in the events he mentions; his impartiality is indubitable, as he nowhere betrays the least resentment against his countrymen, and the factious partisans of Cleon, who had banished him from Athens. The history of Thucydides was so admired by Demosthenes, that he transcribed it eight different times, and read it with such attention, that he could almost repeat it by heart. He had returned from exile in the year 403 B. C.; but it is considered as doubtful whether he died at Athens, or in Thrace, the country of his wife. The time of his death has not been ascertained.

The work of Thucydides was first printed by Aldus, Venet. 1502, fol. And the Greek scholia issued from the same press in 1503. The next edition of the history was printed by Junta, Florent. 1526, fol. An edition by Junta in 1506 is commonly mentioned by bibliographers, but this date is supposed to be erroneous. Other editions were published, by Camerarius at Basel in 1540, by Stephanus at Paris in 1564 and 1588. The latter added the Latin version of Laurentius Valla, which had been twice printed before the year 1500. His editions were followed by that of Æmilius Portus, Francof. 1594, fol. After an interval of a century, a valuable edition was published by Dr Hudson, Oxon. 1696, fol. Another edition was undertaken by Joseph Wasse; but the task, which his death left imperfect, was completed by Duker, Amst. 1731, 2 tom. fol. Some useful editions succeeded, before the appearance of that revised by Bekker, and containing the scholia, together with the annotations of Wasse and Duker, Oxon. 1821, 4 tom. 8vo. Nor must we omit the edition of Goeller, Lipsiæ, 1826,

---

[3] Collinson's Life of Thuanus, with some Account of his Writings, and a Translation of the Preface to his History. Lond. 1807, 8vo.

2 tom. 8vo. A valuable edition, with English notes, chiefly historical and geographical, has more recently been published by Dr Arnold, Oxford, 1830–5, 3 vols. 8vo. Poppo's very elaborate edition of Thucydides is now in the progress of publication. The first volume was printed at Leipzig in 1821, and nine or ten have successively appeared. Here we must not neglect to recommend another work to the reader's attention, Dodwell's "Annales Thucydidei et Xenophontei, præmisso adparatu, cum Vitæ Thucydidis Synopsi chronologica." Oxon. 1702, 4to.

Thucydides has been translated into many of the modern languages. In 1550 an English translation, not however from the Greek text, but from the French version of Claude Seyssel, was published by Thomas Nicolls, "citezeine and goldsmyth of London." A translation of the original was published by Hobbes in 1628, and another by Dr William Smith in 1753–4. A new version, illustrated with copious annotations, has very recently been published by Dr Bloomfield, Lond. 1829, 3 vols. 8vo.

THULE, or Thylæ, in *Ancient Geography*, an island in the most northern parts of the German Ocean. Its situation was never accurately ascertained by the ancients, hence its present name is unknown by modern historians. Some suppose that it is the island now called Iceland, or part of Greenland, and others that it is Foula.

THUNDER, the noise occasioned by the explosion of a flash of lightning echoed back from the inequalities on the surface of the earth, in like manner as the noise of a cannon is echoed, and in particular circumstances forms a rolling lengthened sound. See Electricity.

THUNDERBOLT. When lightning acts with extraordinary violence, and breaks or shatters any thing, it is called a *thunderbolt;* which the vulgar, to fit it for such effects, suppose to be a hard body, and even a stone.

THURGAU, or Thurgovia, a canton of Switzerland. It is bounded on the north-west by the Rhine, on the north-east by the lake of Constance, on the south-east by St Gall, and on the south-west by Zürich. It extends over 265 square miles, is divided into eight circles, and in 1838 contained 84,124 inhabitants, of whom 72,191 were of the reformed church, and 18,500 adhered to the Roman Catholic profession. The canton has five cities, six market-towns, and 284 villages. The force required as the contingent to the general confederation is 1520 men, and the pecuniary contribution amounts to L.2280. The capital is the town of Frauenfeld, on the river Murg, with 1600 inhabitants. In the northern part the face of the country is either level or undulating, but in the south is rather hilly than mountainous, none of the elevations exceeding 2500 feet. The Rhine is the main stream, which receives the waters of the Murg, the Thur, the Sitter, and the smaller brooks. The climate is healthy and temperate. The chief pursuit is agriculture, which affords a sufficiency of corn, good crops of hemp and flax, and abundance of fruit and wine. There is some coal near Frauenfeld. The pasturage feeds upwards of 25,000 cows, and supplies large quantities of butter and cheese. The fishing on the lake of Constance is highly productive of salmon and other fine fish.

THURINGIA, a division of the circle of Upper Saxony, in Germany. It is a fruitful tract, abounding in corn, especially wheat; in black cattle, sheep, and horses. It is about seventy-three miles in length, and as much in breadth.

THUROCZ, a palatinate or district of the province of the Hither Danube, in the Austrian kingdom of Hungary. It extends over 460 square miles, but contains only about 45,000 inhabitants, of whom two thirds are Lutherans, and the remainder of the Greek church. The soil is poor, and the climate mountainous and raw; and the country better adapted for breeding cattle than for growing corn. The chief corn raised is buckwheat; but excellent crops of turnips and carrots are produced. The district produces no wine. The chief article for sale is the cheese of the milch cows. The district comprises four circles, six market-towns, and ninety-eight villages, besides a few hamlets, and it confers the dignity of a palatine on the noble family of Erbober. The capital is St Martin, a town situated on the river which gives its name to the palatinate, and contains about 2000 persons.

THURROCK-GRAYS, a small town of the hundred of Chafford, in the county of Essex, twenty-five miles from London. It stands on the banks of the Thames, near St Clement's Reach. It has a market on Thursday. In 1831 the inhabitants amounted to 1248.

THURSDAY, the fifth day of the Christian week, but the sixth of that of the Jews.

THURSO, a seaport town, borough of barony, and parish on the north-west side of the county of Caithness. The town is situated on the river Thurso, which here falls into the bay of the same name, and by it is divided into two parts. The old portion of the town is irregularly built and ill paved; but the new part is built on a regular plan, and contains a better class of houses, with a handsome new church, town-house, and other buildings for carrying on the public business connected with the customs, excise, and banking. The harbour will only admit vessels of ten feet draught of water at stream tides; the entrance is also much obstructed by a bar, and, for want of a pier or breastwork of stone, vessels, after getting over the bar, can only unload or load at low water. Besides this inconvenience, the bay of Thurso is too dangerous to admit of its ever being a resort for shipping. Notwithstanding these disadvantages, there is a considerable coasting trade, and the inhabitants of the town and immediate neighbourhood are extensively engaged in fisheries, tanning, bleaching, and spinning. Thurso is a place of great antiquity, but was not erected into a borough of barony until the year 1633, when Charles I. granted a charter with the usual powers and privileges. It is governed by two bailies, a dean of guild, and twelve councillors. The population of the town amounted in 1831 to about 2700, and of the parish to 4679.

THYRSUS, in *Antiquity*, the sceptre which the poets put into the hand of Bacchus, and with which they furnished the Menades in their Bacchanalia.

TIARA, an ornament or dress with which the ancient Persians covered their head, and with which the Armenians and the kings of Pontus are represented on medals; these last, because they were descended from the Persians. Latin authors call it indifferently *tiara* and *cidaris*. Strabo says the tiara was in the form of a tower; and the scholiast on Aristophanes affirms that it was adorned with peacocks' feathers.

Tiara is also the name of the pope's triple crown. The tiara and keys are the badge of the papal dignity; the tiara of his civil rank, and the keys of his spiritual jurisdiction. As soon as the pope is dead, his arms are represented with the tiara alone, without the keys. The ancient tiara was a round high cap. John XXIII. first encompassed it with a crown. Boniface VIII. added a second crown, and Benedict XII. a third.

TIBER, a great river of Italy, which runs through the pope's territories, passing by Perugia and Orvietto; and having visited Rome, falls into the Tuscan Sea at Ostia, fifteen miles below that city.

TIBET, a country of great extent, in Independent Tartary, stretching from east to west 1500 miles in length. It extends from the sources of the Indus to the borders of China, and from Hindustan to the great desert of Cobi, in Central Asia. It is of unequal breadth, and many parts of it are unknown. It is distinguished by different names. It is called Tibbet in Bengal; but in Nepaul, Lower Tibet receives the appellation of Kutchar, and in Hindustan that of Potyid. In the native language of the inhabitants it is called Pue, or Puekoachim; the first being the term for northern, and the latter for snow; thus indicating the severity of the climate. The distinguishing feature of this country is its great elevation, being for the most part a table-land, in which the rivers of India and China which run south and east, and those also which run northward into Siberia and Tartary, take their rise. Tibet is separated, about the twenty-eighth degree of north latitude, from Bootan by the Sumoonang Mountains, part of the great Himalaya chain; and the boundaries are marked by a long row of little inscribed flags, fixed in rude heaps of stones, which were seen by Turner when he passed, fluttering in the wind. The summit of one of the mountains, Chumularee, constitutes the highest land in what is called Little Tibet. It is highly venerated by the Hindus, who resort thither for the purpose of paying their adorations to the snow-clad summit.

Tibet appears at first under a most unfavourable aspect to travellers, and to be in a great measure incapable of culture. It is mountainous towards its frontier bordering on Bootan. Here perpetual winter may be said to reign; the great mountain of Chumularee is for ever clothed with snow. Its elevation is not precisely known, but this circumstance indicates a height of several thousand feet. In other parts the country exhibits low rocky hills, where no vegetation is visible, and extensive arid plains, of the most stern and stubborn aspect, and extremely barren. Where the country is capable of cultivation, the usual crops are wheat, pease, and barley. In many parts the grain never ripens. About fourteen miles from Phari, on the frontier mountains, Turner saw a small enclosure of green wheat, which had just strength enough to give out its ear, but which, he was told, would proceed no farther, the cold being too intense to admit of its ripening. It is cultivated merely as forage for cattle, when the plains become bare of grass, and they are hindered from going abroad during the depth of winter. The periodical rains give birth to a little herbage, whose growth stops immediately as they cease: from the extreme dryness of the air, the grass then begins to wither, so that it may be crumbled between the fingers into dust. Yet large droves of cattle are fed in this neighbourhood, the pasture, though short and dry, being extremely sweet and nutritive; and animals ranging in a state of nature are found to prefer it to the more exuberant herbage of milder climates. These plains accordingly, as well as the adjacent mountains, are frequented by large droves of cattle, shawl-goats, deer, musk-deer, horses, great multitudes of foxes, and other wild animals; also by many coveys of partridges and pheasants, and some quails. It is the practice of the cultivators in Tibet to flood the low lands on the approach of winter with water, which freezes and covers their surface with a sheet of ice, and thus shelters them from the violent winds, which would strip off the scanty soil. In some parts they pluck up the corn by the root, and afterwards place it in small bundles to dry. From Phari, in the mountains, however, to Nainee, a distance of fifty miles, the country is very little removed in its aspect, population, or culture, from a perfect desert. The hills are bare, and composed of a stiff, dry, mouldering rock, which splits and shivers with the frost; and, on account of the severity of the climate, the inhabitants are obliged to seek for shelter in the valleys and hollows. The north winds, meeting with no interruption in the wide and barren plains, sweep along in furious blasts of the most cutting severity; and so uniform is the intense cold, that the inhabitants are in the practice of killing their meat at the beginning of winter, and keeping it for three months, at the end of which period it is perfectly fresh.

Seasons.

In Tibet the temperature and seasons exhibit a remarkable uniformity, both in their periodical duration and in their return; and they exactly resemble those in the more southern region of Bengal. Variable weather prevails in the spring from March to May; the climate is warm, with thunder-storms and occasional refreshing showers. From June to September is the season of rains, which being heavy and continued, refresh the country, and cause the rivers to overflow, and, descending with rapidity from the mountains in their progress to the sea, to assist in inundating Bengal. From October to March the sky is uniformly clear; it is neither obscured by fogs nor clouds; and a much more intense degree of cold prevails than is known in the same latitudes in Europe. In these elevated plains the most boisterous winds perpetually prevail, in the dry summer months raising clouds of dust, almost intolerable to the traveller; and in other seasons, says Turner, "conveying a degree of cold unknown even in the severest winters in Europe. Such is sometimes the intenseness of the frost here, though in so low a latitude as twenty-eight degrees, that animals exposed in the open fields are found dead with their heads absolutely split by its force."[1]

Animals.

The country, though barren, is not, as already observed, destitute of animal life; it abounds in a great variety of wild fowl, game, beasts of prey, flocks, droves and herds of cattle. Among the most remarkable animals is the Yak of Tartary, named also the Soora Goy, or bushy-tailed bull of Tibet. This animal resembles an English bull in height, the general figure of the body, the head, and the legs. He is the *bos grunniens* of modern naturalists. See MAMMALIA. These cattle, though not large boned, yet, from the profuse quantity of hair with which they are provided, seem to be of great bulk. They have a downcast heavy look, and appear, as indeed they are, sullen and suspicious, discovering much impatience at the approach of strangers. They pasture on the coldest parts of Tibet, on the short herbage peculiar to the summits of mountains and to bleak plains; their favourite haunt being the chains of mountains situated between twenty-seven and twenty-eight degrees north latitude, whose summits are usually covered with snow. During the severity of winter they take shelter in the southern glens; and in milder seasons they take a wider range on the northern aspect of the mountains. They form a very valuable property to the tribes of itinerant Tartars, who live in tents, and tend them from place to place: they at the same time afford their herdsmen an easy mode of conveyance, a good covering, and wholesome subsistence. These animals are strong, sure footed, and carry a great weight. They are never employed in agriculture; but are extremely useful as beasts of burden. They afford an abundance of rich milk, the butter produced from which is excellent. It is the custom to preserve this in skins and bladders, and the air being excluded, it will keep in this cold climate throughout the year. The musk-deer is another animal which abounds in Tibet, in the vicinity of the coldest mountains, and produces a valuable article of revenue. He delights in the most intense cold, and in places which border the line of perpetual snow. He has two long curved tusks, which proceed from the upper jaw, and, being directed downwards, seem intended principally to serve him for the purpose of digging roots, his usual food; or they may be also given as weapons of defence. These animals are about the height of a moderately sized hog, to which they bear a resemblance in the bigness of the body; but they are still more like the hog-deer. They have a small head, a thick and round hind quarter, no snout, and extremely delicate limbs. The body is covered with prodigiously copious hair, which grows erect all over the body, between two and three inches long, lying smooth only where it is short, on the head, legs, and ears. On examination it seems to partake more of the nature of feathers, or of the porcupine's quills, than of hair, though it is thin, flexible, and not straight, but undulated. The musk is a secretion formed in a little bag or tumour, resembling a wen, situated at the navel, and is found only in the male. The musk-deer is here deemed the property of the state, and hunted only by the permission of the government. Another animal of great importance in Tibet is the goat, whose coat affords materials for that exquisitely fine and beautiful manufacture, the shawl. Captain Turner saw numbers of this valuable animal feeding, in large flocks, upon the thin dry herbage that covers those naked looking hills. It is the most beautiful species among the whole tribe of goats; of various colours, black, white, of a faint bluish tinge, and of a shade somewhat lighter than a fawn. They have straight horns, and are of a lower stature than the smallest sheep in England. The outward covering of the animal is of coarse long hair; but the wool that is next the skin is of a light fine texture; and its softness is preserved by the external coat. This delicate creature is indebted for the softness of its coat to the nature of the climate which it inhabits; and it will not thrive in the hot atmosphere of Bengal, nor will it bear transportation by sea. A breed of wild horses is found in Tibet, which are distinguished for their fleetness, and which are never taken alive, so as to be rendered serviceable, or domesticated; and even when they are taken young they pine away and die, being vicious, stubborn, and untameable. They are said to be hunted, and, when they are killed, their flesh is esteemed a great delicacy. The domestic horses which they use are extremely docile. They are not natives of Tibet, but are brought from Eastern Tartary and the borders of Toorkistan as merchandise. They are never shod. Before they are permitted to be transported, care is taken to deprive them of the power of propagating their species, and mares are never met with in the country. They are quiet, sure-footed creatures, but slow and ugly. Among the valuable animals of Tibet, their breed of sheep merits a distinguished place. Their flocks are numerous, and their chief reliance is placed on them for present support, as well as for winter food. A peculiar species seems indigenous in this climate, marked almost invariably by black heads and legs. They are of a small size, with soft wool; and their flesh, which is almost the only animal food eaten in Tibet, is of a very fine flavour. They are occasionally employed as beasts of burden, and numerous flocks of them are often to be seen laden with salt and grain, each carrying from twelve to twenty pounds. They are the bearers of their own wool to the best market, where it is usually fabricated into a narrow cloth resembling frieze, or a thick coarse blanket. When slaughtered, their skins are most commonly cured with the wool on, and form a most excellent defence against the winter cold to the peasant and the traveller. The skins of lambs are also cured with the wool on, and constitute a valuable article of traffic; and to obtain the skin in its highest perfection, the dam is sometimes killed before her time of yeaning, by which a silky softness is secured for the fleece, which gives it a very high value. It serves particularly for lining vests, and is in equal estimation all over Tartary, as well as in China.

---

[1] Turner's Embassy to the Court of Teshoo Lama in Tibet, p. 210.

Minerals. Though the soil of Tibet is in general barren and unimprovable, and though no great return can ever be expected from agriculture, the country abounds in mineral wealth, and industry and skill are only wanting to turn these sources to account. Gold is found in great quantities, and frequently very pure. It is obtained sometimes in large masses, lumps, and irregular veins. It is also found in the beds of rivers in the form of gold dust, and at their several bendings generally attached to small pieces of stone, with every appearance of its having been a larger mass. Cinnabar, containing a large portion of quicksilver, is found in Tibet, and might be advantageously extracted by distillation if fuel were more plentiful; but it is remarkably scarce, which is a great disadvantage; and they are often forced to substitute for fire-wood the dried dung of animals. The most valuable discovery that could be made for Tibet would be a coal-mine; and this mineral is found in some parts of the country bordering on China. Two days' journey from Teshoo Loomboo there is a lead-mine. The ore is much the same as that found in Derbyshire, mineralized by sulphur, and the metal is easily obtained, namely, by the simple operation of fusion. Copper-mines are found, which furnish materials for the manufacture of idols, and all the ornaments disposed about the monasteries on which gilding is bestowed. Iron is more frequently to be found in Bootan than in Tibet; and it is not a branch of industry which could be followed in Tibet, owing to the want of fuel for smelting the valuable ores. Rock-salt is obtained in great abundance; and tincal is found in the bed of a lake about fifteen days' journey from Teshoo Loomboo. The country contains inexhaustible quantities of it. It is brought to market in the state in which it is dug out of the lake, and afterwards refined into borax in this country.

Tibet carries on trade with the surrounding states, though not to any great extent; the inhabitants not being either commercial or industrious, and the surplus produce of the country being besides inconsiderable. Neither is commerce favoured by the government, the first member of the state being a merchant, who enjoys a monopoly for himself and others of all the chief branches of trade. The exports consist of gold, musk, tincal, goats' hair, and rock-salt. The goats' hair is conveyed to Cashmere, and is of that superior sort of which the celebrated shawls are manufactured; and the salt is exported to Nepaul and Bootan. A considerable commerce is carried on with China, for the most part at a garrison town on the western frontier of China named Silling or Sinning. The exports are gold dust, precious stones, musk, and woollen cloths; in return for which are received gold and silver brocades, silks, teas, tobacco, quicksilver, China ware, furs, and some silver bullion. Gold dust, musk, and tincal, are exported to Bengal; and the imports are broad cloth, trinkets, spices, particularly cloves, pearls, coral, amber, kincobs, Maulda cloths, Rungpoor leather, tobacco, and indigo. British manufactures of woollen would furnish a considerable article of import. The extreme rigour of the climate requires warm clothing; and the dress of the lower classes consists of woollens of an inferior kind, and in winter of sheep or foxes' skins cured with the wool and fur on. When they travel, they carry a weight of clothing that bids defiance to the most piercing winds. Having no other manufactures, they are obliged to encumber themselves with a heavy load of their own rude clothing. When woollen cloths of a better description are brought to the country by the travelling merchants who frequent it, they are bought up with great eagerness. The better classes are dressed in silks and furs. A trade is also carried on with Russia, though not to any great extent. This principally consists in hides, which are prepared in the adjacent districts, and are brought also from Kalmuc Tartary to the same mart, where all the rich and valuable furs that pass in merchandise between the Russians and Chinese may be procured on easy terms. There are few manufactures, and those only such as are of the coarsest kind and required for domestic use. They are famous, however, for the manufacture of images. At Teshoo Loomboo there is an extensive board of works established under the direction of the monastery, which is constantly employed in this manufacture.

Respecting the religion of the inhabitants of Tibet, little is known. It seems to be a schismatical offspring of the religion of the Hindoos, deriving its origin from one of the followers of that faith, a disciple of Buddh, who first broached the doctrine which now prevails over the wide extent of Tartary. It is reported to have been first received in that part of Tibet adjacent to India, which hence became the seat of the sovereign lamas; to have traversed over Mantchieux Tartary, and to have been ultimately disseminated over China and Japan. However it may differ from the Hindoo in many of its outward forms, it still bears a close affinity with the religion of Brahma in many important particulars. The principal idol in the temples is the Buddha of Bengal, worshipped under the denomination of Mahamoonie, a sanscrit term meaning "great saint," and under various other epithets over all Tartary, and among the nations to the east of the Brahmapootra. The same places are considered sacred in Tibet and in Bengal, and are resorted to by pilgrims; and the water of the Ganges, which is considered holy, is carried in loads from the river over the mountains of Tibet, on the shoulders of men, who are hired by enthusiasts for this pious purpose. Their ritual or ceremonial worship differs, however, materially from the Hindoo; the Tibetians assemble in chapels, and in prodigious numbers, to join in chanting alternate recitative and chorus, with the accompaniment of an extensive band of loud and powerful instruments; so that it forcibly impressed on those who heard it, the solemn sounds of the popish mass. The people play in private on many other musical instruments; and Turner mentions, that on a visit to the mother of Teshoo Lama, she sung a very pleasing air, which she accompanied on the guitar, and her husband on the flageolet. The religion of Tibet is entirely free from the illiberal and perplexing distinctions of castes. A Brahmin would deem it a profanation of the deepest dye even to eat in presence of one of an inferior caste, much more to partake of the same repast with a person of a different religion. But the inhabitants of Tibet have no such scruples; even the sovereign lama has no objection to drink tea from the same vessel with any foreigner. Turner mentions, also, that in the great variety of visitors that came to him, he never observed the slightest scruple to partake either of tea or of other liquors prepared by his own servants. The Hindoo pays the blindest reverence to the Brahmin class. This reverence is only paid, in the ignorant idolatry of the Tibetians, to the sovereign lama, immaculate, immortal, and omnipresent, esteemed the vicegerent of the only God, the mediator between mortals and the Supreme. They view him as perpetually absorbed in religious duty, and when called upon to attend to the concerns of mortals, as being employed only in the benign office of distributing comfort and consolation, forgiveness and mercy. He is also the centre of all civil government, which derives from his authority all influence and power. He is the head of the whole system, which is a regular gradation from the most venerated lama, through the whole order of gylongs, to the young noviciate. The inferior gradations, from the president, who is always styled lama, are gylong, tohba, and tuppa. For the performance of daily service in the temple at Teshoo Loomboo there are 3700 gylongs or priests; and four lamas chosen from amongst them superintend and direct their religious ceremonies. Youth intended for the service of the monastery are received into the establishment at the age of eight or ten years. They are then called tuppa, and are occupied in receiving instruction suited to their age. At fifteen they are usually admitted into the order of tohba, if found sufficiently qualified; and thence into the order of gylong between the age of twenty-one and twenty-four. They are then eligible to the superintendence of some endowed monastery, of which there are multitudes spread all over Tibet, with lands assigned them for their support; their promotion depending on their interest or their character. In this station, as chief of a flock, they are honoured with the appellation of lama. Those who enter the religious order are enjoined sobriety, celibacy, and all the austere practices of the cloister. There is a considerable number of nunneries as well as monasteries; and the strictest prohibitions exist against any woman even accidentally passing a night within the walls of the one, or a man within those of the other. The ecclesiastical class, who hold intercourse with heaven, are entirely divided from the lay class, who carry on the business of the world; and no interference ever interrupts the regulated duties of the clergy. Their religion is divided into two sects, who are extremely hostile to each other, and one of whom was forced to seek shelter from the persecution of their opponents in that tract of country bordering on Tibet towards the south, and marked by a high ridge, inhospitable in the extreme, but which was thought capable of affording them a safe retreat. Here they fixed their abode, while others of the same sect still live in tents, and tend their flocks, rambling from place to place. The priests are habited in long robes of yellow cloth, with a conical cap of the same colour; and this peculiarity of colour is adopted as a distinction to mark one of the two religious sects that divide almost the whole of Tartary, from Toorkistan to the eastern limits of this continent. The other colour is red; and the tribes are known as belonging to the red or the yellow cap. The former differ principally from the sectaries of the yellow in admitting the marriage of the priests; but the latter are considered as the more orthodox, as well as possessed of greater influence. The emperor of China is decidedly a votary of the yellow sect, and has sanctified it by a sumptuary law, which limits it to the service of religion and the imperial use. Dalai Lama, Teshoo Lama, and Taranaut Lama, preside over the yellow, who have their residences at Pootalah, Teshoo Loomboo, and Kharka. This sect prevails over a great part of Tibet, and a branch of it is said to be established in the Deccan. In like manner, three lamas preside over the red sect. The principal of the red class in Tibet has his residence in Sakia. The dress of these religious orders is the regular costume of every attendant at court, consisting of a vest of woollen cloth, with sleeves of a deep garnet colour; and a large mantle, either of the same or of a thinner texture, resembling a shawl, a sort of philibeg, and huge boots of bulgar hides, lined either with fur or cloth, complete their equipage.

Diseases.

Of the diseases in this country, the most singular is a glandular swelling in the throat, which is found in Europe among the inhabitants of mountainous countries, and is generally ascribed to an impregnation of the water from snow. This, however, is a doubtful theory, as it is sometimes seen where snow is not to be found. It has been little attended to, as it is not painful, is seldom fatal, and is only common among the poorer class of the people. The small-pox is a most fatal disorder in Tibet. It is not less dreaded than the plague, and is hardly less fatal; for they neither know nor use any remedies for it, but, as soon as it appears in any village, the healthy desert the sick, and leave them to chance and the natural course of the disease. There is little variety in their other diseases. Coughs, colds, and rheumatisms are more frequent than in Bengal. Fevers arise occasionally from temporary causes, but seldom prove fatal. The hot bath is used in many disorders, particularly in bowel complaints and cutaneous eruptions. The hot wells of Tibet are resorted to by thousands.

Customs, manners.

A singular and licentious practice is said by travellers to prevail here, namely, of one woman cohabiting with a whole family of brothers. Turner states, that one woman was pointed out to him who lived with five brothers, to each of whom she was married; and he states that this custom, so contrary to purity of morals and any idea of social happiness, is common among all ranks; and that families are seen living happily in this impure manner. He even endeavours to find out plausible reasons for the practice, founded on the danger in a poor country of the too rapid increase of population. It cannot be considered, however, in any other light than as a mark of gross barbarity and licentiousness; and it agrees well with the author's account of their loose conduct before they marry, and the want of chastity in the women. Their marriage ceremonies are simple, consisting only in the mutual consent of the two parties; and neither the one nor the other is at liberty to withdraw, unless, as Turner expresses it, "the same union of sentiment that joined their hands should prompt their separation." In other words, they are considered to be bound until they tire of each other, when they are left at liberty to form a new alliance; a proof, along with former facts, of their want of morals. In their manners they are mild, humane, and kind; and always obliging without being servilely officious.

It is the custom in Tibet to preserve the mortal remains of the sovereign lamas; but, with this exception, every other corpse is consumed by fire, or exposed in the open air to be devoured by ravens, kites, and other carnivorous birds. In the most populous parts of the country the dogs are also allowed to prey upon this extraordinary carrion. A chief lama, as soon as he expires, is placed upright in an apparent attitude of devotion, his legs being folded under him with each thigh resting on the instep, and the soles of the feet turned upwards. In this posture they are deposited in shrines. The inferior lamas are usually burned, and their ashes deposited in little metallic idols; but common subjects are treated with less ceremony, as already mentioned.

History.

The history of Tibet is involved in obscurity. They have no annals of their public transactions, nor of the ancient extent of their kingdom, or of their religious institutions. It is known, however, that about the year 1720 the emperor of China acquired the sovereignty of Tibet by interfering in the quarrel of the two contending parties. In 1792 the country was invaded by the Nepaulese without provocation, and they made such a rapid and unexpected progress, and appeared so suddenly before Teshoo Loomboo, as scarcely to allow the lama and his gylongs time to effect their escape across the Brahmapootra. The Nepaulese army having carried off a large plunder, the accumulated contributions of ages, from Teshoo Lomboo, and having despoiled the tombs of their most valuable ornaments, withdrew to their own country, whither they were pursued by the Chinese, defeated, and forced to sue for peace, of which one of the conditions was the restoration of the plunder they had taken at Teshoo Loomboo, and the payment of an annual tribute. Since this period the country has enjoyed profound peace. But the spiritual influence of the lamas has been much weakened by that of their earthly protectors, the emperors of China. They retain officers or residents at the court of Lassa, styled umbas, invested with all real authority; and maintain a constant intercourse with the court of Pekin by means of jacoos, which means "communicators of intelligence," and who duly report to China every thing that takes place in Tibet. (F.)

TIBULLUS, Albius, a very elegant poet, was born at Rome about the year of the city 690. He belonged to the equestrian order; but as his father had espoused the cause of Pompey, his estate was impaired in the issue of the unhappy contest which ensued. About the age of twenty-two, the son retired to his villa at Pedum, and by the cultivation of his demesne endeavoured to retrieve his fortune. Love and poetry likewise occupied no inconsiderable share of his attention; and the names, real or fictitious, of his mistresses, Delia, Neæra, and Nemesis, are familiarly known to all classical readers. He had contracted a friendship with Messala Corvinus, who was distinguished by his eloquence as well as by his military talents. The inhabitants of Pannonia having revolted in the year of Rome 718, Augustus employed this general to reduce them to subjection. He invited Tibullus to accompany him, nor did the poet shrink from the toils and dangers of such an expedition. When Messala was soon afterwards raised to the consulship, he composed the panegyric which appears at the beginning of his fourth book of Elegies. It is however written in hexameters, and in a style inferior to that of his elegiac verse. The same distinguished individual was in 725 intrusted with an extraordinary command in Syria, and was again accompanied by Tibullus; but he soon became so seriously indisposed, that he was sent on shore and left in the island of Phæacia. This was poetic ground, and here he composed the third elegy of his first book. Having afterwards been enabled to resume his voyage, he attended his friend through Cilicia, Syria, Egypt, and Greece. Aquitania revolted in the course of the ensuing year, when Messala was despatched on another expedition, being still attended by the poet; and having reduced this province, he in 727 obtained the honour of a triumph, in which the military services of Tibullus entitled him to some share. This was the last of his warlike expeditions, and he now returned to his favourite pursuits. He lived on terms of intimacy with Horace, who has addressed to him one of his odes and one of his epistles. Macer and Valgius were likewise among the number of his poetical friends. He appears to have cherished the love of freedom, and to have scorned to advance his fortunes by flattering Augustus. According to the authority of Domitius Marsus, a poet of that age who wrote his epitaph, he died nearly at the same time with Virgil:

> Te quoque Virgilio comitem non æqua, Tibulle,
> Mors juvenem campos misit ad Elysios,
> Ne foret aut elegis molles qui fleret amores,
> Aut caneret forti regia bella pede.

Virgil died in the year of Rome 735; and if Tibullus died in the same year, he may have attained the age of forty-five. As he is represented by Marsus as a young man, he must have been under the age of forty-six. His loss was bewailed by Ovid in an affectionate elegy.

> Flebilis indignos, Elegeïa, solve capillos:
> Ah nimis ex vero nunc tibi nomen erit!
> Ille tui vates operis, tua fama, Tibullus
> Ardet in extructo, corpus inane, rogo.

Horace has described him as handsome in his person, as blessed with riches, and the art of enjoying them. Tibullus is always classed among the most tender and elegant of the Latin poets who have written in elegiac verse. He has more correctness, though certainly not more fancy, than Ovid, and is less mythological than Propertius. The cadence of his verse is often very pleasing.

The poems of Tibullus have very frequently been printed along with those of Catullus and Propertius. In this form, they were first printed at Venice in quarto about the year 1472; and several other impressions followed within a brief interval. Two editions issued from the press of Aldus, Venet. 1502–15, 8vo. And in the mean time appeared the edition of Junta, Florent. 1503, 8vo. An edition was published by Janus Dousa, several by Joseph Scaliger; and others which deserve particular notice are those of Morel in 1604, and of Passerat in 1608. Omitting other editions of the three poets, we hasten to state that the first separate edition of Tibullus was printed in quarto about the year 1472. This was speedily followed by at least other two editions without dates; and by a third, "cum commentario Bernardini (Cyllenii) Veronensis," Romæ, 1475, 4to. An edition with a commentary was published by a learned Portugueze, Achilles Statius, Venet. 1567, 8vo. For a more recent and valuable edition we are indebted to Janus Broukhusius, Amst. 1708, 4to. Another edition, sometimes described as the best, was published by Vulpius, Patavii, 1749, 4to. The next deserving particular notice is the third edition published by Heyne, Lipsiæ, 1798, 8vo. We shall close this enumeration by mentioning the edition of Wunderlich, Lips. 1817, 2 tom. 8vo. A supplement to it was published by Dissen in 1819.

An English translation of Tibullus was produced by Mr Dart in 1720. A more elegant version, accompanying the original, and illustrated with copious notes, was published by Dr Grainger in 1759, in 2 vols. 12mo. The translator, a man of literature and taste, soon afterwards distinguished himself by the publication of *The Sugar Cane;* a classical poem founded on a subject which it required no mean talents to invest with the graces and allurements of poetry.[1]

TIBUR, a town of ancient Latium, pleasantly situated on the Anio. Here Horace had his villa and house, and here he wished to end his days.

TICAO Isle, one of the Philippine Islands, situated due south of the large island of Luzon, about twenty-eight miles in length by seven in average breadth. Here the Spanish galleon used to take in water and provisions before setting sail for Acapulco. Long. 123. 40. E. Lat. 12. 36. N.

TICHFIELD, a town of the hundred of that name, in the division of Portsdown, in Hampshire, seventy-eight miles from London. The parish is very extensive, and includes a good roadstead for vessels in the bay of that name, near the mouth of Southampton water. Near to it are the remains of a Cistertian abbey. There is a market on Saturday. The inhabitants amounted in 1821 to 3528, and in 1831 to 3712.

TICKARY, a town of Hindustan, province of Bahar, fifty miles south by west from Patna. Long. 84. 55. E. Lat. 24. 58. N.

TICKELL, Thomas, an English poet, was the son of the Rev. Richard Tickell, and was born in 1686, at Bridekirk in Cumberland. He was educated at Queen's College, Oxford, of which he became a fellow. While he continued at that university, he addressed to Addison a complimentary copy of verses on his opera of Rosamond, which introduced him to an acquaintance with that gentleman, who, discovering his merit, became his sincere friend. On Addison being made secretary of state, he appointed Tickell his under secretary; and on his being obliged to resign that office on account of his ill health, he recommended him so effectually to Mr Craggs, his successor, that he was continued in his post till that gentleman's death. In 1724, Tickell was appointed secretary to the lords justices in Ireland, and enjoyed that place as long as he lived. He wrote some poems, which, when separately published, met with a favourable reception, and passed through several editions. After Mr Addison's death, Tickell had the care of the edition of his works printed in four vols. 4to; to which he prefixed an account of the author's life, and a poem on his death. Tickell died in the year 1740.

TICKHILL, a town of the hundred of Strafforth and Tickhill, in the west riding of the county of York, 156 miles from London. The church is a large and ancient building. The town was fortified, but its defences were destroyed in the civil wars. It has at present little or no trade. There is a market on Friday. The inhabitants amounted in 1821 to 1830, and in 1831 to 2018.

TICOO, a cluster of small islands near the west coast of Sumatra. These islands were frequented by the early voyagers for pepper, and the Dutch and English had factories on them, but they were expelled in 1621. They are small and woody, and are about a mile and a half distant from each other. Long. 99. 13. E. Lat. 0. 6. S.

TICOS, a small island in the Pacific Ocean, near the east coast of the island of Luzon. Long. 124. E. Lat. 14. 10. N.

TIDES.

The alternate rising and falling which are observed to take place in the surface of the waters, generally twice in the course of a lunar day, or of 24^{h} 49^{m} of mean solar time, on most of the shores of the ocean, and in the greater part of bays, firths, and rivers which communicate freely with it, are the phenomena denominated *the tides*. These form what are called a *flood* and an *ebb*, a *high* and *low water*. The whole interval between high and low water is called a *tide;* the water is said to *flow* and to *ebb;* and the rising is called the *flood tide*, and the falling the *ebb tide*. This rise or fall of the waters is exceedingly different at different places, and is also variable everywhere. At Plymouth, for instance, it is sometimes twenty feet between the greatest and least heights of the water in one day, and sometimes only twelve feet. These different heights of tide succeed each other in a regular series, diminishing from the greatest to the least, and then increasing from the least to the greatest. The greatest is called a *spring tide*, and the least a *neap tide*. This series is completed in about fifteen days. More careful observation shows that two series are completed in the time of a lunation. For the spring tide in any place happens at a certain interval of time, generally between one and two days, after new or full moon; and the neap tide at a certain interval after the quarter: or, more accurately speaking, the spring tide occurs when the moon has got a certain number of degrees eastward either from the line of conjunction with the sun or of opposition to him, and the neap tide when she is at a certain distance from her first or last quadrature. Thus the whole series of tides appears to be chiefly regulated by the moon, and seems to be only to a small extent under the influence of the sun; for it is further observed that high water happens when the moon has nearly a certain position with respect to the meridian of the place of observation, preceding or following the moon's southing by a certain interval of time; which, at new and full moon, is generally not far from being constant with respect to the same place, but very different in different places; whereas the interval between the time of high water and noon changes almost everywhere about six hours in the course of a fortnight.

The interval between two succeeding high waters is variable. It is shortest about new and full moon, being then about 12^{h} 19^{m}; and about the time of the moon's quadratures it is 12^{h} 30^{m}. But these intervals are somewhat different at different places. The tides in similar circumstances are greatest when the moon is in the equator, and at her smallest distance from the earth, or in her perigee; and, gradually diminishing, are smallest when she is in her apogee, and farthest from the equator.

Such are some of the more general and regular phenomena of the tides. In certain places there are four tides in the lunar day, in others but one; and in some there is scarcely any perceptible variation of level, which regularly keeps time with the moon. The tides being important to all commercial nations, great exertions have recently been made to obtain the means of predicting them. Some account of these and other empirical researches, which have of late been conducted on an extensive scale and with great care, will be given in the latter part of this article.

---

[1] Dr Grainger published a professional work, which has escaped the notice of some of his biographers: "Historia Febris Anomalæ Batavæ, annorum 1746, 1747, 1748, &c. Accedunt Monita Siphylica. Auctore Jacobo Grainger, M. D." Edinb. 1753, 8vo. The latter tract is a reprint of his inaugural dissertation, on taking his degree. An edition of this volume was subsequently published in Holland.

History.

It is of tides, most probably, the Bible speaks, when God is said to set bounds to the sea, and to say, "thus far shall it go, and no farther." Homer would be the earliest profane author who notices the tides, if indeed it be to them he refers (in the 12th book of the Odyssey) when he speaks of Charybdis rising and retiring thrice a day. Herodotus and Diodorus Siculus speak more distinctly of the tides in the Red Sea. Pytheas of Marseille is the first who says any thing of their cause. According to Strabo, he had been in Britain, where he must have observed the tides of the ocean. Plutarch says expressly that Pytheas ascribed them to the moon. It is remarkable that Aristotle says so little about the tides. The army of Alexander, his pupil, were startled at first seeing them near the Persian Gulf; and Aristotle would probably be well informed of all that had been observed there. But in all his writings there are only three passages concerning them, and these are very trivial. In one place he speaks of great tides in the north of Europe; in another, of their having been ascribed by some to the moon; and in a third, he says, the tide in a great sea exceeds that in a small one.

The Greeks had little opportunity of observing the tides. The conquests and the commerce of the Romans gave them more acquaintance with them. Cæsar speaks of them in the fourth book of his Gallic War. Strabo, after Posidonius, classes the phenomena into daily, monthly, and annual. He observes, that the sea rises as the moon approaches the meridian, whether above or below the horizon, and falls again as she rises or falls; that the tides increase at the time of new and full moon, and are greatest at the summer solstice. Pliny explains the phenomena at some length, and ascribes them to the sun and moon dragging the waters along with them (b. ii. c. 97). Seneca (*Nat. Quest.* iii. 28) speaks of the tides with correctness; and Macrobius (*Somn. Scip.* i. 6) gives a tolerable description of their motions. Such phenomena naturally exercise human curiosity as to their cause. Plutarch (*Placit. Phil.* iii. 17), Galileo (*Syst. Mund.* dial. 4), Riccioli in his *Almagest*, ii. p. 374, and Gassendi, ii. p. 27, have collected most of the notions of their predecessors on the subject; but they are of so little importance as not to deserve our notice. Kepler, in accounting for the tides (*De Stella Martis*, and *Epit. Astron.* p. 555), had evidently been aware of the principle of gravitation, but not of the law. He says that all bodies attract each other, and that the waters of the ocean would all go to the moon were they not retained by the attraction of the earth. He then proceeds to explain their elevation under the moon and on the opposite side, because the earth is less attracted by the moon than the nearer waters, but more than the waters which are more remote. The honour of a complete explanation of the tides in a general way was reserved for Sir Isaac Newton. He laid hold of this class of phenomena as the most incontestable proof of universal gravitation, and has given a most beautiful and synoptical view of the whole subject; contenting himself, however, with merely exhibiting the chief consequences of the general principle, and applying it to the phenomena with singular address.

Theory of the tides.

The investigation of the phenomena of the tides has been justly considered as uniting some of the greatest difficulties that occur in the various departments of natural philosophy and astronomy. It implies, first, a knowledge of the laws of gravitation, concerned in the determination of the forces immediately acting on the sea, and of the periods and distances of the celestial bodies, which modify the magnitudes and combinations of these forces; and, secondly, of the hydraulic theories of the resistances of fluids, and of the motions of waves and undulations of all kinds, and of the theoretical determination of the form and density of the earth, as well as of the geographical observation of the breadth and depth of the seas and lakes which occupy a part of its surface; so that the whole subject affords abundant scope for the exercise of mathematical skill, and still more for the employment of that invention and contrivance which enables its possessor to supersede the necessity of prolix computations wherever they can be avoided.

The history of the theory of the tides is naturally divided into several periods in which its different departments have been progressively cultivated. The ancients from the times of Posidonius and Pytheas, and the moderns before Newton, were contented with observing the general dependence of the tides on the moon, as following her transit at an interval of about two hours, and their alternate increase and decrease not only every fortnight, but also in the lunar period of about eight years. The second step consisted in the determination of the magnitude and direction of the solar and lunar forces, by which the general effects of the tides were shown, in the *Principia*, to be the necessary consequences of these forces. The third great point was the demonstration of Maclaurin, that the form of an elliptic spheroid affords an equilibrium under the action of the disturbing forces concerned; while the further contemporary illustrations of the subject by Euler and Bernoulli, though they afforded some useful details, involved no new principle that can be put in competition with Maclaurin's demonstration. The fourth important step was made by Laplace, who separated the consideration of the *form* affording mere equilibrium, from that of the *motion* occasioned by the continual change of that form; while former theorists had taken it for granted that the surface of the sea very speedily assumed the figure of a fluid actuated by similar forces, but remaining perfectly at rest, or assuming instantly the form in question. Laplace's computation is however limited to the case of an imaginary ocean, of a certain variable depth, assumed for the convenience of calculation, rather than for any other reason. Dr Thomas Young has extended Laplace's mode of considering the phenomena to the more general case of an ocean covering a part only of the earth's surface, and more or less irregular in its form; he has also attempted to comprehend in his calculations the precise effects of hydraulic friction on the times and magnitudes of the tides. As far as the resistance may be supposed to vary in the simple ratio of the velocity, Dr Young's theory is sufficiently complete, and explains several of the peculiarities which are otherwise paradoxical in their appearance; but there still remains a difficulty to be combated with respect to the effects of a resistance proportional to the square of the velocity, and this, it is hoped, will be in great measure removed in the present article, which, however, from the space that is allotted to it, must be considered rather as a supplementary fragment than as a complete treatise. This theory will be divided into four sections: the first relating to the contemporaneous progress of the tides through the different seas and oceans, as collected from observation only; the second to the magnitude of the disturbing forces tending to change the form of the surface of the earth and sea; the third to the theory of compound vibrations with resistance; and the fourth to the application of this theory to the progress and successive magnitudes of the tides, as observable at any one port.

SECT. I.—*Of the Progress of Contemporary Tides, as inferred from the times of High Water in different Ports.*

The least theoretical consideration relating to the tides, is that of their progress through the different parts of the ocean, and of its dependent seas. The analysis of these ought to be very completely attainable from direct observation, if the time of high water had been accurately observed at a sufficient number of ports throughout the world; and, on the other hand, if the earth were covered in all parts with a fluid of great and nearly uniform depth, the tides of this fluid would be so regular, that a very few observations would be sufficient to enable us to deduce the whole of the phenomena from theory, and to trace the great waves, which would follow the sun and moon round the globe, so as to make its circuit in a day, without any material deviation from uniformity of motion and succession. Having collected, for the actual state of the sea and continents, an abundant store of accurate observations of the precise time of high water with regard to the sun and moon, for every part of the surface, and having arranged them in a table according to the order of their occurrence, as expressed in the time of any one meridian, we might then suppose lines to be drawn on a terrestrial globe, through all the places of observation, in the same order; and these lines would indicate, supposing the places to be sufficiently numerous, so as to furnish a series of tides very nearly contemporary, the directions of the great waves, to which that of the progress of the tides in succession must be perpendicular. If, however, we actually make such an attempt, we shall soon find how utterly inadequate the observations that have been recorded are, for the purpose of tracing the forms of the lines of contemporary high water with accuracy or with certainty, although they are abundantly sufficient to show the impossibility of deducing the time of high water at any given place from the Newtonian hypothesis, or even from that of Laplace, without some direct observation. It might at least be supposed very easy to enumerate the existing observations, scanty as they may be, in a correct order; but there is a number of instances in which it is wholly uncertain whether the time observed at a given port relates to the tide of the same morning in the open ocean, or to that of the preceding evening. This inconvenience may, however, in some measure be remedied, by inserting such places in two different parts of the table, at the distance of twelve and a half hours from each other. The following table is the result of an approximation obtained in this manner, the principal hour-lines having been partially traced on a map of the world, in order to afford some little direction to the correct insertion of the times of high water without the material error of half a day.

Time of High Water at the Full and Change of the Moon, reduced to the Meridian of Greenwich.

It may be immediately inferred from this table, first, that the line of contemporary tides is seldom in the exact direction of the meridian, as it is supposed to be universally in the theory of Newton and of Laplace; except, perhaps, the line for the twenty-first hour in the Indian Ocean, which appears to extend from Socotora to the Almirantes and the Isle of Bourbon, lying nearly in the same longitude. Secondly, the southern extremity of the line advances as it passes the Cape of Good Hope, so that it turns up towards the Atlantic, which it enters obliquely, so as to arrive, nearly at the same moment, at the Island of Ascension, and at the Island of Martin Vaz, or of the Trinity. Thirdly, after several irregularities about the Cape Verd Islands, and in the West Indies, the line appears to run nearly east and west from St Domingo to Cape Blanco, the tides proceeding due northwards; and then, turning still more to the right, the line seems to run north-west and south-east, till at last the tide runs almost due east up the British Channel and round the north of Scotland into the Northern Ocean, sending off a branch down the North Sea to meet the succeeding tide at the mouth of the Thames. Fourthly, towards Cape Horn, again, there is a good deal of irregularity; the hour-lines are much compressed between South Georgia and Tierra del Fuego, perhaps on account of the shallower water about the Falkland Islands and South Shetland. Fifthly, at the entrance of the Pacific Ocean, the tides seem to advance very rapidly to New Zealand and Easter Island; but here it appears to be uncertain whether the line of contemporary tide should be drawn nearly north and south from the Gallapagos to Tierra del Fuego, or north-east and south-west from Easter Island to New Zealand; or whether both these partial directions are correct: but on each side of this line there are great irregularities, and many more observations are wanting before the progress of the tide can be traced with any tolerable accuracy, among the multitudinous islands of the Pacific Ocean, where it might have been hoped that the phenomena would have been observed in their greatest simplicity, and in their most genuine form. Lastly, of the Indian Ocean the northern parts exhibit great irregularities, and among the rest they afford the singular phenomenon of one tide in the day, observed by Halley in the port of Tonkin, and explained by Newton in the *Principia:* the southern parts are only remarkable for having the hour-lines of contemporary tides considerably crowded between New Holland and the Cape of Good Hope, as if the seas of these parts were shallower than elsewhere.

These inferences respecting the progress of the tides are not advanced as the result of any particular theory, nor even as the only ones that might possibly be deduced from the table. Thus the supposion that the direction in which the tides advance must be perpendicular to the hour-lines of contemporary tides, is not by any means absolutely without exception, since a quadrangular lake, with steep shores in the direction of the meridian, would have the times of high water the same for every point of its eastern or western halves respectively, and there could be no correctly defined direction of the hour-lines in such a case. But if any portion of the sea could be considered as constituting such a lake, its properties would be detected by a sufficient number of observations of high water; and the existing table does not appear to indicate any such cases that require to be otherwise distinguished than as partial irregularities. There may also be some doubt respecting the propriety of the addition of twelve and a half hours that has been made to the time of high water in the north-eastern parts of the Atlantic: but it seems extremely improbable that the same tide should travel north-easterly into the English Channel and into the Northern Ocean, and at the same time westerly across the Atlantic, as it must be supposed to do, if it were considered as primarily originating in the neighbourhood of the Bay of Biscay. On the other hand, the bending of the great wave round the continents of Africa and Europe seems to be very like the sort of refraction which takes place on every shelving coast with respect to the common waves, which, whatever may have been their primitive origin, acquire always, as they spread, a direction more and more nearly parallel to that of the coast which they are approaching: and the suppositions which have been here advanced respecting the succession of the tides in different ports, allowing for the effect of a multitude of irregularities proceeding from partial causes, appear to be by far the most probable that can be immediately inferred from the table, at least in its present state of imperfection.

SECT. II.—*Of the Disturbing Forces that occasion the Tides.*

Since the phenomena of the tides, with regard to their progress through the different oceans and seas, as they exist in the actual state of the earth's surface, appear to be too complicated to allow us to hope to reduce them to computation by means of any general theory, we must, in the next place, confine our attention to the order in which the successive changes occur in any single port; and having determined the exact magnitude of the forces that tend to change the form of the surface of the ocean at different periods, and having also examined the nature of the vibratory motions of which the sea, or any given portion of it, would be susceptible, in the simplest cases, after the cessation of the disturbing forces, we must afterwards endeavour to combine these causes, so as to adapt the result to the successive phenomena which are observed at different times in any one port.

THEOREM A. ("E."—Nicholson's Journal, July 1813.) The disturbing force of a distant attractive body, urging a particle of a fluid in the direction of the surface of a sphere, varies as the sine of twice the altitude of the body.

The mean attraction exerted by the sun and moon on all the separate particles composing the earth, is exactly compensated by the centrifugal force derived from the earth's annual revolution round the sun, and from its monthly revolution round the common centre of gravity of the earth and moon; but the difference of the attractions exerted at different points of the earth, must necessarily produce a disturbing force, depending on the angular position of the point with regard to the sun or moon, since the centrifugal force is the same for them all; the disturbing force being constantly variable for any one point, and depending partly on the difference of the distance of the point from the mean distance, and partly on the difference of the direction of the luminary from its direction with respect to the centre, or, in other words, on its parallax.

In the case of a sphere covered with a fluid, it will be most convenient for computation to consider both these forces as referred to the direction of the circumference of the sphere, which will differ but little from that of the fluid; and it will appear that both of them, when reduced to this direction, will vary as the product of the sine and cosine of the distance from the diameter pointing to the luminary, that is, as half the sine of twice the altitude: for the difference of gravitation, which depends on the difference of the distance, will always vary as the sine of the distance from the bisecting plane perpendicular to that diameter, and will be reduced to the direction of the surface by diminishing it in the ratio of the cosine to the radius; and the effect of the difference of direction will be originally proportional to the sine of the distance from the diameter, and will in like manner be expressed, when reduced, by the product of the sine and cosine; and each force, thus reduced, will be equal, where it is greatest, to half of its primitive magnitude, since sin. cos. $45^\circ = \frac{1}{2}$. " Thus, the gravitation towards the moon at the earth's surface, is to the gravitation towards the earth as 1 to 70 times the square of $60\frac{1}{2}$, or to 256 217: and the former disturbing force is to the whole of this as 2 to $60\frac{1}{2}$ at the point nearest the moon, and the second as 1 to $60\frac{1}{2}$ at the equatorial plane, and the sum of both, reduced to the direction of the circumference, where greatest, as 3 to 121, that is, to the whole force of the earth's gravitation, as 1 to 10 334 000; and in a similar manner we find, that the whole disturbing force of the sun is to the weight of the particles as 1 to 25 736 000." Or, if we call the moon's horizontal parallax p, and substitute $\frac{1}{p}$ for the distance, the whole of the lunar disturbing force in the direction of the surface will be $\frac{3}{2}\cdot\frac{p^3}{70}=\frac{3}{140}p^3$; or, if z be the moon's zenith distance from any point of the surface, $f=\frac{3}{70}p^3$ sin. cos. z.

THEOREM B. [F.] The inclination of the surface of an oblong spheroid, slightly elliptical, to that of the inscribed sphere, varies as the sine of twice the distance from the circle of contact; and a particle resting on any part of it, without friction, may be held in equilibrium by the attraction of a distant body [situated in the direction of the axis].

If a sphere be inscribed in an oblong spheroid, the elevation of the spheroid above the sphere must obviously be proportional, when measured in a direction parallel to the axis of the spheroid, to the ordinate of the sphere, that is, to the sine of the distance from its equator; and when reduced to a direction perpendicular to the surface of the sphere, it must be proportional to the square of that sine; and the tangent of the inclination to the surface of the sphere, which is equal to the fluxion of the elevation divided by that of the circumference, must be expressed by twice the continual product of the sine, the cosine, and the ellipticity, or rather the greater elevation e, the radius being considered as unity: so that the elevation e will also express the tangent of the inclination where it is greatest, since 2 sin. cos. $45° = 1$; and the inclination will be everywhere as the product of the sine and cosine.

If, therefore, the density of the elevated parts be considered as evanescent, and their attraction be neglected, there will be an equilibrium, when the ellipticity is to the radius as the disturbing force to the whole force of gravitation; for each particle situated on the surface will be actuated by a disturbing force tending towards the pole of the spheroid, precisely equal and contrary to that portion of the force of gravitation which urges it in the opposite direction down the inclined surface. Hence, if the density of the sea were supposed inconsiderable in comparison with that of the earth, the radius being 20 839 000 feet, the greatest height of a lunar tide in equilibrium would be 2·0166 feet, and that of a solar tide ·8097: that is, supposing the moon's horizontal parallax about 57′, and her mass $\frac{1}{70}$ of that of the earth.

THEOREM C. [G.] The disturbing attraction of the thin shell contained between a spheroidical surface and its inscribed sphere, varies in the same proportion as the inclination of the surface, and is to the relative force of gravity depending on that inclination, as three times the density of the shell to five times that of the sphere.

We may imagine the surface of the sphere to be divided by an infinite number of parallel and equidistant circles, beginning from any point at which a gravitating particle is situated, and we may suppose all these circles to be divided by a plane perpendicular to the meridian of the point, and consequently bisecting the equatorial plane of the spheroid: it is obvious, that if the elevations on the opposite sides of the plane be equal at the corresponding points of each circle, no lateral force will be produced; but when they are unequal, the excess of the elevated matter on one side above that of the other side will produce a disturbing or lateral force. Now, the elevation being everywhere as the square of the distance x from the equatorial plane, we may call it ex^2, and the difference corresponding to any point of that semicircle which is the nearer to the pole of the spheroid, will be $e(x'^2 - x''^2) = e(x' + x'')(x' - x'')$. But $x' + x''$ is always twice the distance of the centre of the supposed circle from the equatorial plane; and the distance of this centre from that of the sphere will be cos. ψ, if ψ be the angular distance of the circle from its pole; and calling φ the distance of this pole from the equatorial plane of the spheroid, the distance in question will be cos. ψ sin. φ, and $x' + x'' = 2$ cos. ψ sin. φ; and the difference $x' - x''$ is twice the actual sine of the arc θ in the supposed circle, that is, twice the natural sine, reduced in the ratio of unit to the radius of this circle, which is sin. ψ, reduced again to a direction perpendicular to the equatorial plane; whence $x' - x'' = 2$ sin. θ sin. ψ cos. φ; and $x'^2 - x''^2 = 4$ sin. θ sin. cos. ψ sin. cos. φ. Hence it follows, that, in different positions of the gravitating particle, the effective elevation at each point of the surface, similarly situated with respect to it, is as the product of the sine and cosine of its angular distance φ from the equatorial plane, the other quantities concerned remaining the same in all positions. But the inclination of the surface of the spheroid, as well as the original disturbing force, varies in the same proportion of the product of the sine and cosine of the distance φ; consequently the sum of this disturbing attraction and the original force will also vary as the inclination of the surface, and may be in equilibrium with the tendency to descend towards the centre, provided that the ellipticity be duly commensurate to the density of the elevated parts.

Now, in order to find the actual magnitude of the disturbing attraction for a shell of given density, we must compute the fluent of $4e$ sin. $\theta d\theta$ sin. cos. $\psi d\psi$ sin. cos. φ, reduced first according to the distance and direction of each particle from the given gravitating particle; and we must compare the fluent with $\frac{4}{3}\pi$, the attraction of the whole sphere at the distance of the radius, or unity. But for the angle θ, the portion of the force acting in the common direction of sin. θ is to the whole attraction at the same distance as sin. θ to 1, so that the attractive force of any point of the semicircle will be $4e$ sin.^{2} θ sin. cos. ψ sin. cos. φ, and its fluxion will be as sin.^{2} $\theta d\theta$, of which the fluent is $\frac{1}{2}\theta - \frac{1}{2}$ sin. cos. θ, or when $\theta = 180°$, $\frac{1}{2}\pi$, and $\frac{1}{2}\pi$ sin. ψ will express the effect of the disturbing attraction of the semicircles, of which sin. ψ is the radius, reduced to the direction of the middle point, of which the distance is 2 sin. $\frac{1}{2}\psi$; the reduction for this distance is as its square to 1; and for the direction, as the distance to sin. ψ, together making the ratio of $\frac{\text{sin. }\psi}{8\text{ sin.}^3\frac{1}{2}\psi}$, and the ultimate fluxion of the force will be $2e\pi$ sin. ψ sin. cos. φ sin. cos. $\psi\frac{\text{sin. }\psi}{8\text{ sin.}^3\frac{1}{2}\psi}d\psi = 2e\pi\frac{\text{sin.}^3\psi\text{ cos. }\psi}{8\text{ sin.}^3\frac{1}{2}\psi}$ sin. cos. $\varphi d\psi$; but sin. $\psi = 2$ sin. cos. $\frac{1}{2}\psi$, and the fraction becomes $\frac{8\text{ sin.}^3\text{ cos.}^3\frac{1}{2}\psi}{8\text{ sin.}^3\frac{1}{2}\psi}$ cos. $\psi =$ cos.$^3\frac{1}{2}\psi$ cos. $\psi =$ cos.$^3\frac{1}{2}\psi$(cos.$^2\frac{1}{2}\psi -$ sin.$^2\frac{1}{2}\psi) =$ cos.$^5\frac{1}{2}\psi -$ cos.$^3\frac{1}{2}\psi +$ cos.$^5\frac{1}{2}\psi = 2$ cos.$^5\frac{1}{2}\psi -$ cos.$^3\frac{1}{2}\psi$. Now, taking the fluent from $\psi = 0$ to $\psi = 180°$, we have $2\int'$cos.$^5\frac{1}{2}\psi 2d\frac{1}{2}\psi = \frac{8}{5}\cdot\frac{4}{3}$, and $\int'$ cos.$^3\frac{1}{2}\psi \times 2d\frac{1}{2}\psi = \frac{4}{3}$, the difference being $\frac{3}{5}\cdot\frac{4}{3}=\frac{4}{5}$, whence the fluent of the force is found $2e\pi$ sin. cos. $\varphi\times\frac{4}{5}\times\frac{1}{n}$, calling the density of the fluid $\frac{1}{n}$, or, where it is greatest, sin. cos. φ being $=\frac{1}{2}$, $\frac{4}{5}\frac{e\pi}{n}$, while the attraction of the sphere itself is $\frac{4}{3}\pi$, which is to $\frac{4}{5}\frac{e\pi}{n}$ as 1 to $\frac{3e}{5n}$; and since the elevation e expresses also the maximum of the relative force of gravity depending on the tangent of the inclination (Theorem B), it is obvious that the disturbing attraction $\frac{3e}{5n}$ must be to the relative force e as $\frac{3}{n}$ to 5.

Corollary 1. If $n=1$, as in a homogeneous fluid sphere or spheroid, the disturbing attraction becomes $\frac{3}{5}e$, and this attraction, together with the primitive force f, must express the actual elevation e, or $\frac{3}{5}e+f=e$, whence $f=\frac{2}{5}e$, and $e=\frac{5}{2}f$, giving 2·024 and 5·042 for the magnitude of the solar and lunar tides, when $f=\cdot 8097$ and 2·0166 respectively. But this is obviously far from the actual state of the problem.

Corollary 2. Supposing $n=5{\cdot}4$ (see Quarterly Journal of Science, April 1820), we have $\frac{3e}{27}+f=e$, and $e=\frac{27}{24}f=\frac{9}{8}f$; so that the height of the primitive tides of an ocean of water, covering the whole surface of the earth, such as it actually is, ought to be ·911 for the solar, and 2·27 for the lunar disturbing force; that is, supposing the sea without inertia, so as to accommodate itself at once to the form of equilibrium. But, in the actual state of the irregularities of the seas and continents, it is impossible to pay any regard to this secondary force, since the phenomena do not justify us in supposing the general form of the surface of the ocean such as to give rise to it.

Theorem D. [H.] When the horizontal surface of a liquid is elevated or depressed a little at a given point, the effect will be propagated in the manner of a wave, with a velocity equal to that of a heavy body which has fallen through a space equal to half the depth of the fluid, the form of the wave remaining similar to that of the original elevation or depression. Dr Young's Elementary Illustrations of the Celestial Mechanics of Laplace, 378, p. 318.

Scholium. The demonstration of this theorem implies that water is incompressible, and that the pressure of each particle placed on the surface is instantaneously communicated through the whole depth of the fluid to the bottom. These suppositions are not indeed strictly accurate in any case, but they introduce no sensible error when the surface of the wave similarly affected is large in comparison with the depth of the fluid. A modern author of celebrity seems to have taken it for granted that the pressure is propagated with the same velocity downwards and laterally; at least, if such is not his meaning, he has been somewhat unfortunate in the choice of his expressions; but there seems no reason whatever why water should communicate force more slowly when it is perfectly confined, than ice would do; and the divergence of the pressure of a certain portion of the surface of water, elevated a little, for example, above the rest, may be compared to the *divergence* of a sound entering into a detached chamber by an aperture of the same size with the given surface, which is probably *small* in comparison with its direct motion, but *equally rapid*, and in both cases depending on the modulus of the elasticity of the medium.

Theorem E. [I.] A wave of a symmetrical form, with a depression equal and similar to its elevation, striking against a solid vertical obstacle, will be reflected, so as to cause a part of the surface, at the distance of one fourth of its whole breadth, to remain at rest; and if there be another opposite obstacle at twice that distance, there may be a perpetual vibration between the surfaces, the middle point having no vertical motion. Dr Young's Natural Philosophy, vol. i. p. 289, 777.

Scholium 1. The elevation and depression of a spheroid, compared with the surface of the sphere of equal magnitude, exhibits a symmetrical wave in the sense of the proposition; and it is not necessary that the shores should be very rocky or perpendicular, in order to produce a strong reflection; for even the vibration of the water in the bottom of a common hemispherical basin is considerably permanent.

Corollary 3. The vibrations of the water supposed to be contained in a canal, following the direction of the equator, and 90° in length, would be synchronous with the passage of a wave 180° in breadth, over any point of a canal of the same depth, and surrounding the whole globe.

Scholium 2. It has been usual to consider the elevation of the tides as identical with that of an oblong spheroid, measured at its vertex, and therefore as amounting to twice as much as the depression of the same spheroid at the equator, considered in relation to the mean height belonging to a sphere of the same magnitude; but the supposition is by no means applicable to the case of a globe covered partially and irregularly with water, so that in almost all cases of actual tides, the elevation must be considered as little if at all greater than the depression, as far as this cause only is concerned; there are, however, some other reasons to expect that the elevation of the great wave might often arrive at a distant port in somewhat greater force than the depresssion.

Theorem F. [K.] The oscillations of the sea and of lakes, constituting the tides, are subject to laws exactly similar to those of pendulums capable of performing vibrations in the same time, and suspended from points which are subjected to compound regular vibrations, of which the constituent periods are completed in half a lunar and half a solar day [or in some particular cases a whole day].

Supposing the surface of the sea to remain at rest, each point of it would become alternately elevated and depressed, in comparison with the situation in which it might remain in equilibrium; its distance from this situation varying according to the regular law of the pendulum (see Theorem B); and, like all minute vibrations, it will be actuated by forces indirectly dependent on, and proportional to, this distance; so that it may be compared to a pendulous body remaining at rest in the vertical line, about which its point of suspension vibrates, and will consequently follow the motion of the temporary horizon, in the same manner as the pendulum follows the vibration of its point of suspension, either with a direct or a retrograde motion, according to circumstances, which will be hereafter explained: the operation of the forces concerned being perfectly analogous, whether we consider the simple hydrostatic pressure depending on the elevation, or the horizontal pressure derived from the inclination of the surface, or the differential force immediately producing elevation and depression, depending on the variation of the horizontal pressure, and proportional to the curvature of the surface. It becomes therefore necessary, for the theory of the tides, to investigate minutely the laws of these compound and compulsory vibrations, which, together with the resistances affecting them, will be the subject of the next section.

SECT. III.—*Of the Effects of Resistance in Vibrating Motions, whether Simple or Compound.*

THEOREM G. If $\mathrm{d}w + A\mathrm{d}s + Bs\mathrm{d}s + Dw\mathrm{d}s = 0$, we have $e^{Ds}\left(w + \frac{B}{D}s + \frac{AD-B}{DD}\right) = c$; hl$e$ being $= 1$.

Scholium. For the better understanding of the mode of investigation which will be employed in these propositions, it will be proper to premise some remarks on the investigation of fluxional equations, by means of multipliers. A person unacquainted with the language of modern mathematicians, would naturally understand by a "criterion of integrability," some mode of distinguishing an expression that would be integrated, from one that was untractable; while, in fact, this celebrated criterion relates only to the accidental form in which the expression occurs, and not to its essential nature. If we take, for instance, the well-known case of the fluxion of hl $\frac{x}{y} = \text{hl}x - \text{hl}y$, we have $\frac{\mathrm{d}x}{x} - \frac{\mathrm{d}y}{y} = \frac{y\mathrm{d}x - x\mathrm{d}y}{xy}$, and making this $= 0$, we have also $y\mathrm{d}x - x\mathrm{d}y = 0$; and this expression no longer fulfils the conditions of integrability, until we multiply it again by $\frac{1}{xy}$, and restore it to its perfect form. The direct investigation of such a multiplier is generally attended by insuperable difficulties; and the best expedient, in practical cases, is to examine the results of the employment of such multipliers as are most likely to be concerned in the problem, with indeterminate co-efficients, and to compare them with the equations proposed. In common cases, the finding of fluents, when only one variable quantity is concerned, requires little more than the employment of a table of fluents or integrals such as that of Meier Hirsch; and the truth of the solution is in general tested at once, for each case, by taking the fluxion of the quantity inserted in the table: but for the separation of different variable quantities, where they are involved with each other, the employment of proper multipliers is one of the most effectual expedients; and it is still more essential to the solution of equations between fluxions of different orders, or their coefficients. Such equations require in general to be compared with some multiple of the exponential quantity e^{mt}, which affords fluxions of successive orders, that have simple relations to each other, especially when $\mathrm{d}t$ is considered as constant. The multiples of sin. Ct, and cos. Ct, are also very useful in such investigations, and for a similar reason; but the solutions that they afford are commonly less comprehensive than the former, though they are often simpler, and more easily obtained. It is not however necessary that the exponent of the multiplier should flow uniformly, as will appear from the first example of a problem which has been solved by Euler in his Mechanics: the subsequent examples will possess somewhat more of novelty.

Demonstration. The fluxion of $e^{ns}\ (w + ps + q)$ is $e^{ns}(\mathrm{d}w + p\mathrm{d}s + (nw + nps + nq)\mathrm{d}s) = e^{ns}\ \mathrm{d}w + (p + nq)\ \mathrm{d}s + n\mathrm{d}s\mathrm{d}s + nw\mathrm{d}s)$; and comparing with this $e^{ns}\ (\mathrm{d}w + A\mathrm{d}s + Bs\mathrm{d}s + Dw\mathrm{d}s)$, we have $n = D$, $np = B$, and $p = \frac{B}{n} = \frac{B}{D}$; and, lastly, $p + nq = A$, $q = \frac{A-p}{n} = \frac{AD-B}{DD}$; consequently the fluxion of $e^{Ds}\left(w + \frac{B}{D}s + \frac{AD-B}{DD}\right)$ is equal to nothing, and that quantity is constant, or equal to c.

Example. Let the given equation be that of a cycloidal pendulum, moving with a resistance proportional to the square of the velocity, or $\frac{\mathrm{dd}s}{\mathrm{d}t^2} + Bs - D\frac{\mathrm{d}s^2}{\mathrm{d}t^2} = 0$.

Scholium 2. The space s being supposed to begin at the lowest point of the curve, the fluxion $\mathrm{d}s$ is negative during the descent on the positive side, and the force $\mathrm{dd}s$ is consequently negative, and equal, when there is no resistance, to Bs, B being a positive co-efficient, equivalent, in the case of gravitation, to $\frac{2g}{l}$ or $\frac{32}{l}$, l being the length of the pendulum, and g the descent of a falling body in the first second. The co-efficient $-D$ is negative, because the resistance acts in a contrary direction to that of the force Bs, as long as s remains positive, and coincides with it on the negative side. But in the return of the pendulum the signs are changed, so that the equation can only be applied to a single vibration; since the two forces in question oppose each other in the same points of the curve in which they before agreed, while the square $\frac{\mathrm{d}s^2}{\mathrm{d}t^2}$ must always remain positive.

Solution. If we multiply the given equation by $\mathrm{d}s$, and make the square of the velocity, or $vv = w = \frac{\mathrm{d}s^2}{\mathrm{d}t^2}$, we have $\mathrm{d}s\frac{\mathrm{dd}s}{\mathrm{d}t^2} + Bs\mathrm{d}s - D\frac{\mathrm{d}s^2}{\mathrm{d}t^2}\mathrm{d}s = 0 = \frac{1}{2}\mathrm{d}w + Bs\mathrm{d}s - Dw\mathrm{d}s$, and $\mathrm{d}w + 2Bs\mathrm{d}s - 2Dw\mathrm{d}s = 0$; which, compared with the theorem, gives us 0 for A, $2B$ for B, and $-2D$ for D; and the solution becomes $e^{-2Ds}\left(w - \frac{B}{D}s - \frac{B}{2DD}\right) = c$, or $w = \frac{B}{D}s + \frac{B}{2DD} + ce^{2Ds}$; and if $w = 0$ when $s = \lambda$, we have $\frac{B}{D}\lambda + \frac{B}{2DD} + ce^{2D\lambda} = 0$, or, putting $\frac{B}{D}\lambda + \frac{B}{2DD} = \beta$, $\beta + ce^{2D\lambda} = 0$, and $c = -\beta e^{-2D\lambda}$; β being also $= \frac{B\gamma}{2DD}$, if $\gamma = 1 + 2D\lambda$. We may also substitute σ for $\lambda - s$, and ce^{2Ds}, $= -\beta e^{2D(s-\lambda)}$, will become $= -\beta e^{-2D\sigma}$, and $w = \frac{B}{D}s + \frac{B}{2DD} - \beta e^{-2D\sigma} = \frac{B}{2DD}(1 - \gamma e^{-2D\sigma} + 2Ds)$. Now $e^{-2D\sigma} = 1 - 2D\sigma + 2D^2\sigma^2 - \frac{4}{3}D^3\sigma^3 + \frac{2}{3}D^4\sigma^4 - \ldots$; and $(1 + 2D\lambda)\ e^{-2D\sigma} = 1 + 2D\lambda - 2D\sigma - 4D^2\lambda\sigma + 2D^2\sigma^2 + 4D^3\lambda\sigma^2 - D\tfrac{4}{3}{}^3\sigma^3 - \ldots$; whence $w = \frac{B}{2DD}(2Ds - 2D(\lambda - \sigma) + 4D^2\lambda\sigma - 2D^2\sigma \ldots) = \frac{B}{2DD}(4D^2\lambda\sigma - 2D^2\sigma^2 - 4D^3\lambda\sigma^2 \ldots) = B\left(2\lambda\sigma - \gamma\sigma^2 + \frac{2}{3}D\gamma\sigma^3 - \frac{1}{3}D^2\gamma\sigma^4 + \ldots\right)$.

Corollary 1. From this solution we obtain the point at which the velocity is greatest; and, by reversing the equation, we may also find the extent of the vibration. For when $\mathrm{d}w = 0$, we have $Bs\mathrm{d}s = Dw\mathrm{d}s$, and $Bs = Dw$, which is the obvious expression of the equality of the resistance to the propelling force. Putting the greatest value of $w = \varkappa$, and the corresponding value of $s = \varsigma$, we have $\varkappa = \frac{B}{D}\varsigma + \frac{B}{2DD} + ce^{2D\varsigma} = \frac{B}{D}\varsigma$, since $B\varsigma = D\varkappa$, and $\frac{B}{2DD} = -ce^{2Ds} = \frac{B\gamma}{2DD}e^{2D(\varsigma-\lambda)}$; whence $\frac{1}{\gamma} = e^{2D(\varsigma-\lambda)}$, and $\gamma = e^{2D(\lambda-\varsigma)}$; consequently $\mathrm{hl}\gamma = 2D(\lambda-\varsigma) = \mathrm{hl}(1+2D\lambda)$, and $2D\varsigma = 2D\lambda - \mathrm{hl}(1+2D\lambda)$, and $\varsigma = \frac{1}{2D}\left(2D^2\lambda^2 - \frac{8}{3}D^3\lambda^3 + \ldots\right) = D\lambda^2 - \frac{4}{3}D^2\lambda^3 + \ldots$ And since $\varkappa = \frac{B}{D}\varsigma$, we have $\varkappa = \frac{B}{2DD}(2D\lambda - \mathrm{hl}[1 + 2D\lambda])$.

Lemma. For the reversion of a series, or of a finite equation, if $z = ax + bx^2 + cx^3 + \ldots$, we have $x = \frac{1}{a}z - \frac{b}{a^3}z^2 + \frac{2b^2 - ac}{a^5}z^3 - \frac{5b^3 - 5abc + a^2d}{a^7}z^4 + \frac{14b^4 - 21ab^2c + 6a^2bd + 3a^2c^2 - a^3e}{a^9}z^5 - \ldots$

The proof of this well-known formula is the most readily obtained by means of a series with indeterminate co-efficients, such as $x = Az + Bz^2 + \ldots$, which, by actual involution, and by comparison with the proposed series, will give the required values of the co-efficients, as expressed in this Lemma.

Corollary 2. When $w = 0$, we obtain from its value, divided by $B\sigma$, the equation $2\lambda = \gamma\sigma - \frac{2}{3}D\gamma\sigma^2 + \frac{1}{3}D^2\gamma\sigma^3 - \ldots$; and, by reversing this series, we have $\sigma = \frac{2\lambda}{\gamma} + \frac{8}{3\gamma^2}D\lambda^2 + \frac{40}{9\gamma^3}D^2\lambda^3 \ldots$, or $\sigma = 2\lambda - \frac{4}{3}D\lambda^2 + \ldots$; the difference of the arcs of descent and ascent being $\frac{4}{3}D\lambda^2$, and the difference of two successive vibrations $\frac{8}{3}D\lambda^2$, when the resistance is very small; this difference being also $\frac{8}{3}\varsigma$; so that the displacement of the point of greatest velocity is $\frac{3}{8}$ of the difference of the successive vibrations.

Scholium 2. If K be the value of w when Dw would be equal to the force of gravity, and $DK = Bl = 2g$, we have $D = \frac{2g}{K}$, or H being the height from which a body must fall to acquire the velocity $\sqrt{K}$, since $K = 4gH$, $D = \frac{1}{2H}$, and $2D = \frac{1}{H}$.

Scholium 3. It is natural to imagine that we might obtain the time from the equation expressing the velocity in terms of the space, if we merely expanded the value of $\frac{1}{\sqrt{w}}$ into a new series, by means of the Newtonian theorem; but the fluents thus obtained for the expression of the time are deficient in convergency; and a similar difficulty would occur if we expressed σ in terms of w by reversing the series, and divided its fluxion by $\sqrt{w}$. The ingenuity of Euler has, however, devised a method of avoiding these inconveniences, by supposing the time to begin at the point where the velocity is a maximum; and it will be necessary, in this investigation, to follow his steps, with some slight variations.

Corollary 3. In order to find the time of vibration, we take $s - \varsigma = \tau$, and $\varkappa - w = z$, then $s = \tau + \varsigma$, $\sigma = \lambda - \varsigma - \tau$, $w = \frac{B}{2DD}(1 - \gamma e^{-2D(\lambda-\varsigma-\tau)} + 2D[\varsigma + \tau])$, and $\varkappa$ being $= \frac{B}{D}\varsigma$, $z = -\frac{B}{2DD} - \frac{B}{D}\tau + \frac{B\gamma}{2DD}e^{2D(\varsigma-\lambda)}e^{2D\tau}$; but we have seen that $e^{2D}(\varsigma - \lambda) = \frac{1}{\gamma}$, and $-z$ becomes $\frac{B}{2DD} + \frac{B}{D}\tau - \frac{B}{2DD}e^{2D\tau} = \frac{B}{D}\tau - \frac{B}{2DD}\left(2D\tau + 2D^2\tau^2 + \frac{4}{3}D^3\tau^3 + \frac{8}{12}D^4\tau^4 + \ldots\right) = \frac{B}{D}\tau - \frac{B}{D}\tau - B\tau^2 - \frac{2}{3}BD\tau^3 - \ldots = -B\tau^2 - \frac{2}{3}BD\tau^3 - \frac{1}{3}BD^2\tau^4 - \ldots$, and $\frac{z}{B} = \tau^2 + \frac{2}{3}D\tau^3 + \frac{1}{3}D^2\tau^4 + \ldots$ In order to reverse this series, we must put $\frac{z}{B} = y^2$, and $\tau = \mathrm{A}y + \mathrm{B}y^2 + \mathrm{C}y^3 + \ldots$; and by substituting the powers of this series for those of τ in the value of $\frac{z}{B} = y^2 = \tau^2 + \mathrm{P}\tau^3 - \mathrm{Q}\tau^4 + \ldots$, we find $\mathrm{A} = 1$, $\mathrm{B} = -\frac{1}{2}\mathrm{P}$, $\mathrm{C} = \frac{5}{8}\mathrm{P}^2 - \frac{1}{2}\mathrm{Q} \ldots$; and $\tau = y - \frac{1}{3}Dy^2 + \frac{1}{9}D^2y^3 - \ldots$. Hence $\mathrm{d}\tau = \mathrm{d}y - \frac{2}{3}Dy\mathrm{d}y + \frac{1}{3}D^2y^2\mathrm{d}y - \ldots$; and this fluxion, divided by the velocity $v = \sqrt{(\varkappa - z)}$, will be the fluxion of the time; or, since

$$\mathrm{d}\frac{z}{B} = 2y\mathrm{d}y \text{ and } \mathrm{d}y = \frac{\mathrm{d}z}{2By} = \frac{\mathrm{d}z}{2\sqrt{B}\sqrt{z}},$$

$$\mathrm{d}t = \sqrt{\frac{1}{B}} \cdot \frac{\mathrm{d}z}{2\sqrt{(\varkappa z - zz)}} - \frac{D}{3B}\frac{\mathrm{d}z}{\sqrt{(\varkappa - z)}} + \frac{D^2}{6B\sqrt{B}} \cdot$$

$\frac{z\mathrm{d}z}{\sqrt{(\varkappa z - zz)}} - \ldots$: and the fluent becomes $t = \frac{1}{2\sqrt{B}}\,\mathrm{arc}\ v\ \sin.\frac{2z}{\varkappa} - \frac{2D}{2B}\sqrt{(\varkappa - z)} + \frac{D^2}{6B\sqrt{B}}\left(\frac{1}{2}\varkappa\ \mathrm{arc}\ v\ \sin.\frac{2z}{\varkappa} - \sqrt{[\varkappa z - z^2]}\right)\ldots$; the value of which, taken from $z = 0$ to $z = \varkappa$, is $2\frac{\pi}{\sqrt{B}} - \frac{2D}{3B}\sqrt{\varkappa} + \frac{D^2}{3B\sqrt{B}}(\frac{1}{2}\varkappa\pi)\ldots$ If we now make τ negative, for the ascent of the pendulum, the co-efficients P, R, …, B, D, …, will change their signs, and the value of t will be $\frac{\pi}{2\sqrt{B}} + \frac{2D}{3B}\sqrt{\varkappa} + \frac{D^2}{12B\sqrt{B}}\varkappa\pi + \ldots$, the sum of both being $\frac{\pi}{\sqrt{B}} + \frac{D^2\varkappa\pi}{6B\sqrt{B}} + \ldots$, which is the time of a complete vibration, and the difference $\frac{4D}{3B}\sqrt{\varkappa} + \ldots$ The effect of the resistance on the whole time involves, therefore, only the second and the higher powers of the coefficient of the resistance D; and it also disappears with the arc, as $\varkappa$, the square of the greatest velocity, becomes inconsiderable with respect to the velocity itself, and to the time $\frac{\tau}{\sqrt{B}}$.

THEOREM H. If $\frac{\mathrm{dd}s}{\mathrm{d}t^2} + A\frac{\mathrm{d}s}{\mathrm{d}t} + Bs = 0$, $\mathrm{d}t$ being constant, we have $e^{mt}(\mathrm{d}s + as\mathrm{d}t) = c$; m being $= \frac{1}{2}A \pm \sqrt{(\frac{1}{4}A^2 - B)}$, and $a = \frac{1}{2}A \mp \sqrt{(\frac{1}{4}A^2 - B)}$.

Demonstration. The fluxion of $e^{mt}(\mathrm{d}s + as\mathrm{d}t)$ is $e^{mt}(\mathrm{d}^2s + a\mathrm{d}s\mathrm{d}t + (m\mathrm{d}s + ams\mathrm{d}t)\mathrm{d}t) = e^{mt}(\mathrm{d}^2s + (a + m)\mathrm{d}s\mathrm{d}t + ams\mathrm{d}t^2)$; and, comparing this fluxion with the proposed equation, we have, for the co-efficients, $a + m = A$, and $am = B$; whence $\frac{B}{m} + m = A$, $m^2 - Am = -B$, $m = \frac{1}{2}A \pm \sqrt{(\frac{1}{4}A^2 - B)}$, and $a = \frac{1}{2}A \mp \sqrt{(\frac{1}{4}A^2 - B)}$.

Example. Let the equation proposed be that of a cycloidal pendulum, vibrating with a resistance proportional to the velocity; that is, $\frac{\mathrm{dd}s}{\mathrm{d}t^2} + A\frac{\mathrm{d}s}{\mathrm{d}t} + Bs = 0$.

Scholium 1. The resistance is here adequately expressed, in all cases, by the term $A\frac{\mathrm{d}s}{\mathrm{d}t}$, so that the equation is permanently applicable to the successive vibrations. Thus, in the second descent, on the negative side of the vertical line, Bs being negative, and $-s$ becoming nearer to 0, the fluxion ds is positive, and $A\frac{\mathrm{d}s}{\mathrm{d}t}$ is of a contrary character to Bs, as it ought to be.

Solution. Since $m = \frac{1}{2}A \pm \sqrt{(\frac{1}{4}A^2 - B)}$, and $a = \frac{1}{2}A \mp \sqrt{(\frac{1}{4}A^2 - B)}$, it is obvious that the two radical quantities will be either possible or imaginary, according as $\frac{1}{4}A^2$ is greater or less than B.

Case i. If A^2 is greater than $4B$, the resistance being very considerable, the solution becomes

$$e^{\frac{1}{2}At \pm \sqrt{(\frac{1}{4}A^2 - B)}t}\left(\frac{\mathrm{d}s}{\mathrm{d}t} + [\tfrac{1}{2}A \mp \sqrt{(\tfrac{1}{4}A^2 - B)}]s\right) = c;$$

and the velocity $v = -\frac{\mathrm{d}s}{\mathrm{d}t} = (\frac{1}{2}A - \sqrt{[\frac{1}{4}A^2 - B]})s -$

$$ce^{\frac{1}{2} - At - \sqrt{(\frac{1}{4}A^2 - B)}t} = (\tfrac{1}{2}A + \sqrt{[\tfrac{1}{4}A^2 - B]})s -$$

$c'e^{-\frac{1}{2}At + \sqrt{(\frac{1}{4}A^2 - B)}t}$; and if the velocity be supposed to vanish when $s = \lambda$, and $t = 0$, we have $0 = \frac{1}{2}A\lambda - \sqrt{(\frac{1}{4}A^2 - B)}\lambda - c = \frac{1}{2}A\lambda + \sqrt{(\frac{1}{4}A^2 - B)}\lambda - c'$.

Corollary 1. Hence it appears that such a pendulum would require an infinite time to descend to the lowest point, since the velocity cannot have a finite value when s vanishes, the exponential quantity never beginning negative.

Scholium 2. The co-efficient B may also be written for an actual pendulum, as measured in English feet, $\frac{32}{l}$, or $\frac{2g}{l}$, if we call g the descent of a falling body in the first second, which is, however, denoted in the works of some authors by $\frac{1}{2}g$, or even by $\frac{1}{4}g$. If we make $\frac{\mathrm{dd}s}{\mathrm{d}t^2} + \frac{32}{l}s = 0$; when $s = l$, the force becomes such that $-\mathrm{d}^2s = 32\mathrm{d}t^2$, and $-\frac{\mathrm{d}s}{\mathrm{d}t} = 32$, which is the true velocity generated by such a force in a second of time. Supposing k to be the velocity with which the resistance would become equal to the weight, we must have for $A\frac{\mathrm{d}s}{\mathrm{d}t}$, $\frac{32}{k}\frac{\mathrm{d}s}{\mathrm{d}t}$, in order that the force represented by A may become equal to that of gravity, and $A = \frac{2g}{k}$; and if h be the height from which a body must fall to gain the velocity k, since $h = \frac{k^2}{4g}$, $A^2 = \frac{4gg}{kk} = \frac{g}{h}$. Hence it follows, that when $A^2 = 4B$, which is the time of the possibility of alternate vibrations, $\frac{g}{h} = \frac{8g}{l}$, and $h = \frac{1}{8}l$, the resistance becoming equal to the weight when the body has fallen freely through one eighth of the length of the pendulum.

Case ii. Supposing now the resistance to be more moderate, and $\frac{1}{4}A^2$ to be less than B, and making $B - \frac{1}{4}A^2 = C^2$; we shall have $\sqrt{(\frac{1}{4}A^2 - B)} = \sqrt{(-C^2)} = \sqrt{-1}\,C$; the solution of the equation, $\frac{\mathrm{dd}s}{\mathrm{d}t^2} + A\frac{\mathrm{d}s}{\mathrm{d}t} + Bs = 0$, will then be

$$\mathrm{d}\left(e^{\frac{1}{2}At \pm \sqrt{-1}\,Ct}\left[\frac{\mathrm{d}s}{\mathrm{d}t} + \tfrac{1}{2}As \mp \sqrt{-1}\,Cs\right]\right) = 0;$$ whence,

by taking the two different values in succession, and adding together their halves, we obtain $\mathrm{d}\left(e^{\frac{1}{2}At}\left[\frac{e^{\sqrt{-1}Ct} + e^{-\sqrt{-1}Ct}}{2}\right.\right.$

$$\left.\left.(\mathrm{d}s + \tfrac{1}{2}As) + \frac{e^{-\sqrt{-1}Ct} - e^{\sqrt{-1}Ct}}{2}\sqrt{-1}\,Cs\right]\right) = 0;$$ or,

since $\sqrt{-1} = \frac{-1}{\sqrt{-1}}$, $\frac{e^{\sqrt{-1}Ct} + e^{-\sqrt{-1}Ct}}{2}\left(\frac{\mathrm{d}s}{\mathrm{d}t} + \frac{1}{2}As\right)$

$+ \frac{e^{\sqrt{-1}Ct} - e^{-\sqrt{-1}Ct}}{2\sqrt{-1}}Cs = ce^{-\frac{1}{2}At}$. Now the imaginary exponential quantities, thus combined, are the well-known expressions for the sine and cosine of the arc Ct (*Elem. Illustr.* § 358); and the last equation may be written thus, cos. $Ct\left(\frac{\mathrm{d}s}{\mathrm{d}t} + \frac{1}{2}As\right) +$ sin. $CtCs = ce^{-\frac{1}{2}At}$; whence

$$v = -\frac{\mathrm{d}s}{\mathrm{d}t} = \tfrac{1}{2}As + \frac{\text{sin. } Ct}{\text{cos. } Ct}Cs - \frac{ce^{-\frac{1}{2}At}}{\text{cos. } Ct}.$$ This fluent, if

t were made to begin when $v = 0$, would only afford us such expressions as have hitherto been found intractable; but nothing obliges us to limit the problem to this condition, and it is equally allowable to make the time t begin when $v = \frac{1}{2}As$, the corresponding value of s being called ς, then $\frac{1}{2}A\varsigma = v = \frac{1}{2}A\varsigma - c$; consequently $c = 0$. The equation will then become $\frac{\mathrm{d}s}{s} + C\frac{\text{sin.}}{\text{cos.}}Ct + \frac{1}{2}A\mathrm{d}t = 0$; whence hl$s$ — hl cos. $Ct = c' - \frac{1}{2}At =$ hl $\frac{s}{\text{cos. } Ct}$, and $\frac{s}{\text{cos. } Ct} = e^{c' - \frac{1}{2}At}$, or $s = \text{cos. } Ct \cdot e^{c' - \frac{1}{2}At}$; and, when $t = 0$, $s = e^{c'} = \varsigma$; consequently $\frac{s}{\varsigma} = \text{cos. } Ct \cdot e^{-\frac{1}{2}At} = \text{cos. } Ct\left(1 - \frac{1}{2}At + \frac{1}{8}A^2t^2 - \frac{1}{48}A^3t^3 + \ldots\right)$. But since $v = -\mathrm{d}s = s\left(C\frac{\text{sin.}}{\text{cos.}}Ct \cdot \mathrm{d}t + \frac{1}{2}A\mathrm{d}t\right)$, it follows that v must vanish whenever $C\frac{\text{sin.}}{\text{cos.}}Ct + \frac{1}{2}A = 0$, or when ta. $Ct = \frac{-A}{2C}$, that is, in the first instance, very nearly when $Ct = \frac{-A}{2C}$, and $t = \frac{-A}{2CC}$, and $-\frac{1}{2}At = \frac{AA}{4CC}$, and $e^{-\frac{1}{2}At} = 1 + \frac{AA}{4CC}$, very nearly; so that, calling the primitive extent of the arc of vibration $s = \lambda$, we have $\frac{\lambda}{\varsigma} = \text{cos. } Ct\left(1 + \frac{AA}{4CC}\right)$; cos. Ct

being also, in this case, $= \sqrt{\left(1 - \frac{AA}{4CC}\right)} = 1 - \frac{AA}{8CC}$, and $\frac{\lambda}{\varsigma} = 1 + \frac{AA}{8CC}$, and $\frac{\varsigma}{\lambda} = \frac{8CC}{8CC + AA} = \frac{8B - 2AA}{8B - AA} = 1 - \frac{AA}{8B - AA}$, corresponding to the verse sine of the time $\frac{-A}{2CC}$, or to the arc $\frac{-A}{2C}$, in the circle represented by Ct.

Corollary 2. It follows that both v and s must vanish continually at equal successive intervals, whenever ta. $Ct = \frac{-A}{2C}$, and when cos. $Ct = 0$, respectively; the descent to the lowest point will therefore occupy the time corresponding to $\frac{\pi}{4} + \frac{A}{2C}$, and the subsequent ascent to $\frac{\pi}{4} - \frac{A}{2C}$: the extent of the vibrations being always proportional to $e^{-\frac{1}{2}At}$.

Corollary 3. The greatest velocity must take place at the point where $A\frac{ds}{dt} + Bs = 0$, and AC ta. $Ct + \frac{1}{2}A^2 = B$, or ta. $Ct = \frac{B - \frac{1}{2}AA}{AC}$, and cot. $Ct = \frac{AC}{B - \frac{1}{2}AA}$, or, if we neglect A^2, cot. $Ct = \frac{A}{\sqrt{B}} =$ cos. $Ct = \frac{s}{\varsigma}$, very nearly.

Corollary 4. The diminution of the successive vibrations is expressed by the multiplier $e^{-\frac{1}{2}At}$, which, when $Ct = 2\pi$, the whole circumference, is $1 - \frac{A}{C}\pi$, and $\frac{A}{C}\pi\lambda$, or $\frac{A\pi\lambda}{\sqrt{B}}$ is the diminution of the value of s when the pendulum returns to the place from which it first set out, that is, the difference between the lengths of two vibrations, each corresponding to a semicircumference, and this difference is to $\frac{A}{\sqrt{B}}\varsigma$, or $\frac{A}{\sqrt{B}}\lambda$, the displacement of the point of greatest velocity, which measures the greatest resistance, as π to 1, or as 3·1416 to 1. We have seen that, for a resistance varying as the square of the velocity, this proportion was as 8 to 3, or as 2·667 to 1.

Corollary 5. If the pendulum be supposed to vibrate in a second, the unity of time, the diminution of the arc 2λ in each vibration will be $\frac{1}{2}A \times 2\lambda$, and the successive lengths will vary as $e^{-\frac{1}{2}A}\,2\lambda$, $e^{-A}\,2\lambda$, and so forth; and after the number N of vibrations, the extent of the arc will be reduced from 2λ to $e^{-\frac{1}{2}NA}\,2\lambda$; so that if we make $e^{-\frac{1}{2}NA} = M$, we have $\mathrm{hl}\,M = -\frac{1}{2}NA$, and $A = \frac{2}{N}\,\mathrm{hl}\,\frac{1}{M}$. Thus, if in an hour the vibrations were reduced to $\frac{2}{3}$ of their extent, which is rather more than appears to have happened in any of Captain Kater's experiments, we should have $N = 3600$, and $M = \frac{2}{3}$, whence $A = \frac{1}{1800} \times {\cdot}4054651 = {\cdot}00022526$, and $A^2 = {\cdot}000\,000\,050\,75$; and since $B = \frac{32}{l} = 9{\cdot}81$, $C = \sqrt{(B - \frac{1}{4}A^2)} = \sqrt{B}\sqrt{\left(1 - \frac{AA}{4B}\right)} = \sqrt{B}\left(1 - \frac{AA}{8B}\right) = \sqrt{B}\left(1 - \frac{AA}{78{\cdot}5}\right)$; the fraction being only $= {\cdot}000\,000\,000\,65$; or about one second in 1600 millions, that is, in about fifty years.

Scholium 3. Although the isochronism of a pendulum, with a resistance proportional to the velocity, was demonstrated by Newton, yet Euler appears to have failed in his attempts to carry the theory of such vibrations to perfection; for he observes (*Mechan.* ii. p. 312), *Etsi ex his appareat, tempora tam ascensuum quam descensuum inter se esse æqualia, tamen determinari non potest, quantum sit tempus sive descensuum sive ascensuum: neque etiam tempora descensuum et ascensuum inter se possunt comparari. Æquatio enim rationem inter* s *et* u *definiens ita est complicata, ut ex ea elementum temporis* $\frac{ds}{u}$, *per unicam variabilem non possit exprimi.*

Scholium 4. In confirmation of the solution that has been here proposed, it may not be superfluous to show the truth of the result in a different manner. Taking $s = \varsigma e^{mt}$ cos. Ct, we have $\frac{ds}{dt} = \varsigma e^{mt}$ (m cos. $Ct - C$ sin. Ct), and $\frac{dds}{dt^2} = \varsigma e^{mt}$ (m^2 cos. $Ct - Cm$ sin. $Ct - Cm$ sin. $Ct - C^2$ cos. Ct); whence $\frac{dds}{dt^2} + A\frac{ds}{dt} + Bs = \varsigma e^{mt}$ (m^2 cos. $Ct - 2\,Cm$ sin. $Ct - C^2$ cos. $Ct + Am$ cos. $Ct - AC$ sin. $Ct + B$ cos. $Ct) = 0$, and $(m^2 - C^2 + Am + B)$ cos. $Ct - (2Cm + AC)$ sin. $Ct = 0$: an equation which is obviously true when the co-officients of both its terms vanish, and $2Cm = -AC$, or $m = \frac{1}{2}A$; and again $C^2 = m^2 + Am + B = \frac{1}{4}A^2 - \frac{1}{2}A^2 + B = B - \frac{1}{4}A^2$. The former mode of investigation is more general, and more strictly analytical; but this latter is of readier application in more complicated cases, and it will hereafter be further pursued.

Lemma. If a moveable body be actuated continually by a force equal to that which acts on a given pendulum, the body being in a state of rest when the pendulum is at the middle of its vibration, the space described in the time of a vibration will be to the length of the pendulum as the circumference of a circle is to its diameter. For the force being represented by cos. Ct, or cos. x, for the pendulum, it will become sin. x with regard to the beginning of the supposed motion, and the velocity, instead of sin. x, becomes $-$ cos. x, or $1 -$ cos. x; so that the space, instead of $1 -$ cos. x, is $x -$ sin. x, which, at the end of the semivibration, is $x = \frac{\pi}{2}$, instead of $1 -$ cos. $x = 1$, the space described by the simple pendulum, which is equal to its length.

Scholium 5. There is a paradox in the relations of the diminution of the vibration to the distance measuring the greatest resistance, which it will be worth while to consider, in order to guard ourselves against the too hasty adoption of some methods of approximation which appear at first sight unexceptionable. The pendulum, if it set out from a state of rest at the point of greatest resistance, would perform a vibration to the extent of double the distance of that point, or $2\frac{A}{\sqrt{B}}\lambda$, the initial force being measured by that distance. Now, when the resistance is very small, its magnitude may be obtained without sensible error from the velocity of the pendulum vibrating without resistance at the corresponding part of the arc; and the velocity may be supposed to vary as sin. Ct, and the resistance, in the case of this proposition, as sin. Ct or sin. x also. Hence it may be inferred by means of the Lemma, that the whole diminution of the space will be to $\frac{A}{\sqrt{B}}\lambda$ as π to 1, or that it will be equal to $\frac{A}{\sqrt{B}}\pi\lambda$, which has already been found to be the actual difference of two successive semivibrations. The accuracy of this result, however, must depend on the mutual compensation of its errors; for the approximation supposes, that if the resistance vanished at the lowest point, the subsequent retardation would be such as to diminish the space by the effect of the diminution of the velocity acting uniformly through the remainder of the vibration, while in fact the diminution of the space from this cause would be simply equal to a part of the arc proportional to the diminution of the velocity, since the arc of ascent is simply as the velocity at the lowest point. Hence it is obvious, that the effects of the resistance are too much complicated with the progress of the vibration to allow us to calculate them separately; and accordingly, when the resistance is as the square of the velocity, or as $\sin.^2 x$, the diminution of velocity is expressed by $\frac{1}{2}x - \frac{1}{2}\sin. \cos. x$, and that of the space by $\frac{1}{4}x^2 - \frac{1}{4}\sin.^2 x$, which, at the end of a vibration, becomes $\frac{1}{4}\pi^2$ instead of π; that is, since the distance of the point of greatest velocity is here $\varsigma = D\lambda^2$, $\frac{1}{4}\pi^2 D\lambda^2 = 2{\cdot}467\ D\lambda^2$, while the more accurate mode of computation has shown that the true diminution of the space is $2{\cdot}667\ D\lambda^2$. (Theorem G.) If we chose to pursue the mode of approximation here suggested, with accuracy, it would be necessary to consider the resistance as a periodical force acting on a pendulum capable of a synchronous vibration, as hereafter in Theorem K, Schol. 1.

THEOREM J. If $\frac{dds}{dt^2} + Bs + M \sin. Ft = 0$, we may satisfy the equation by taking $s = \sin. (\sqrt{B}.t) + \frac{M}{FF - B} \sin. Ft$.

Demonstration. The value of s here assigned gives us $\frac{ds}{dt} = \sqrt{B} \cos. \sqrt{B}t + \frac{MF}{FF - B} \cos. Ft$, and $\frac{dds}{dt^2} = - B \sin. \sqrt{B}t - \frac{MFF}{FF - B} \sin. Ft$; so that $\frac{dds}{dt^2} + Bs = B \sin. \sqrt{B}t + \frac{MB}{FF - B} \sin. Ft - B \sin. \sqrt{B}t - \frac{MFF}{FF - B} \sin. Ft = \frac{MB - MFF}{FF - B} \sin. Ft = - M \sin. Ft$.

Corollary 1. If, in order to generalize this solution, we make $s = \alpha \sin. \sqrt{B}t + \beta \cos. \sqrt{B}t + \gamma \sin. Ft + \varepsilon \cos. Ft$, we may take any quantities at pleasure for α and β, according to the conditions of the particular case to be investigated; but ε must be $= 0$; that is, the motion will always be compounded of two vibrations, the one dependent on the length of the pendulum, or on the time required for the free vibration, indicated by $\sqrt{B}t$, the other synchronous with Ft, the period of the force denoted by M; the latter only being limited to the condition of beginning and ending with the periodical force.

Corollary 2. In the same manner, it may be shown that the addition of any number of separate periodical forces, indicated by the terms $M' \sin. F't$, $M'' \sin. F''t$, . . . , will add to the solution the quantities $\frac{M'}{F'F' - B} \sin. F't$ $\frac{M''}{F''F'' - B} \sin. F''t$, and so forth.

Example 1. Supposing a pendulum to be suspended on a vibrating centre, and to pass the vertical line at the same moment with the centre, we may make α and $\beta = 0$, and $s = \frac{M}{FF - B} \sin. Ft$ only; the vibration being either direct or reversed, according as F is less or greater than $\sqrt{B}$, or than $\sqrt{\frac{32}{l}}$, which determines the spontaneous vibration of the pendulum.

Example 2. But if the ball of the pendulum be supposed to begin its motion at the moment that the centre of suspension passes the vertical line, we must make $s = \frac{M}{FF - B} (\sin. Ft - \cos. \sqrt{B}t)$; and the subsequent motion of the pendulum will then be represented by the sum of the sines of two unequal arcs in the same circle; and if these arcs are commensurate with each other, the vibration will ultimately acquire a double extent, and nearly disappear in a continued succession of periods, provided that no resistance interfere. And the consequences of any other initial conditions may be investigated in a manner nearly similar. Thus, if the time of free vibration, under these circumstances, were $\frac{1}{3}$ of the periodical time, the free vibration, in which the motion must be supposed initially retrograde, in order to represent a state of rest by its combination with the fixed vibration, would have arrived at its greatest excursion forwards, after three semivibrations, at the same moment with the fixed vibration, and after three complete vibrations more would be at its greatest distance in the opposite direction, so as to increase every subsequent vibration equally on each side, and permanently to combine the whole extent of the separate arcs of vibration. But in this and in every other similar vibration, beginning from a state of rest in the vertical line, that is, at the point where the periodical force is evanescent, the effect of the free or subordinate vibration with respect to the place of the body will obviously disappear whenever an entire number of semivibrations has been performed.

Corollary 3. The paradox stated in the fourth scholium on the last theorem may be illustrated by means of this proposition, and will serve in its turn to justify the mode of computation here employed in a remarkable manner. It has been observed in Nicholson's Journal for July 1813, that the mode of investigating the effects of variable forces, by resolving them into parts represented by the sines of multiple arcs, and considering the vibrations derived from each term as independent in their progress, but united in their effects, may be applied to the problem of a pendulum vibrating with a resistance proportional to the square of the velocity; and that for this purpose the square of the sine may be represented by the series $\sin.^2 x = {\cdot}8484 \sin. x - {\cdot}1696 \sin. 3x - {\cdot}0244 \sin. 5x - {\cdot}00813 \sin. 7x - {\cdot}0029 \sin. 9x - {\cdot}0013 \sin. 11x - \ldots$ Now, if we employ this series for resolving the resistance supposed in Theorem G into a number of independent forces, the greatest resistance being measured by $\frac{A}{\sqrt{B}}\lambda$, we shall have ${\cdot}8484 \frac{A}{\sqrt{B}}\lambda$ for the part supposed to be simply proportional to the velocity, whence, from Theorem H, we have ${\cdot}8484\pi \frac{A}{\sqrt{B}}\lambda$ for the corresponding diminution of the vibration; that is, $2{\cdot}6653 \frac{A}{\sqrt{B}}\lambda$. But it has been observed, in the preceding corollary, that the *place* of the pendulum will not be at all affected by any subordinate vibration after any entire number of complete semivibrations; and the slight effect of the *velocity* left in consequence of these subordinate vibrations may here be safely neglected, so that $2{\cdot}6653 \frac{A}{\sqrt{B}}\lambda$ may be considered as the whole effect of the resistance with respect to the space described, which differs only by $\frac{1}{2000}$ of the whole from $2{\cdot}666\,\frac{A}{\surd B}\lambda$, the result of the more direct computation of Theorem G.

Scholium. An experimental illustration of the accuracy of the theorem may be found in the sympathetic vibrations of clocks, and in that of the inverted pendulum invented by Mr Hardy, as a test of the steadiness of a support (art. PENDULUM, vol. xvii. p. 218); for since the extent of the regular periodical vibration is measured by $\frac{M}{FF-B}$, it is evident, that however small the quantity M may be, it will become very considerable when divided by $FF-B$, as F and $\surd B$ approach to each other; and accordingly it is observed, that when the inverted pendulum is well adjusted to the rate of a clock, there is no pillar so steady as not to communicate to it a very perceptible motion by its regular, though extremely minute, and otherwise imperceptible change of place.

THEOREM K. In order to determine the effect of a periodical force, with a resistance proportional to the velocity, the equation $\frac{dds}{dt}+A\frac{ds}{dt}+Bs=M\text{ sin. }Gt=0$, may be satisfied by taking $s=\alpha\text{ sin. }Gt+\beta\text{ cos. }Gt$, α being $=\frac{GG-B}{(GG-B)^2+AAGG}M$, and $\beta=\frac{AGM}{(GG-B)^2+AAGG}$; s being also $=\surd(\alpha^2+\beta^2)\text{ sin. }\left(Gt+\text{arc ta.}\frac{\beta}{\alpha}\right)=\frac{M}{\surd([GG-B]^2+AAGG)}\text{ sin. }\left(Gt-\text{arc ta.}\frac{AG}{B-GG}\right)$.

Since $s=\alpha\text{ sin. }Gt+\beta\text{ cos. }Gt$, $\frac{ds}{dt}=\alpha G\text{ cos. }Gt-\beta G\text{ sin. }Gt$, and $\frac{dds}{dt^2}=-\alpha G^2\text{ sin. }Gt-\beta G^2\text{ cos. }Gt=-G^2s$; consequently the equation becomes $(B-G^2)(\alpha\text{ sin. }Gt+\beta\text{ cos. }Gt)+\alpha AG\text{ cos. }Gt-\beta AG\text{ sin. }Gt+M\text{ sin. }Gt=0$, and $(B-G^2)\alpha-\beta AG+M=0$, and $(B-G^2)\beta+\alpha AG=0$; whence $\frac{\beta}{\alpha}=\frac{AG}{GG-B}$, also $\beta=\frac{M-(GG-B)\alpha}{AG}=\frac{\alpha AG}{GG-B}$ and $(G^2-B)M-(G^2-B)^2\alpha=\alpha A^2G^2$; consequently $\alpha=\frac{(GG-B)M}{(GG-B)^2+A^2G^2}$, and $\beta=\frac{AGM}{(GG-B)^2+A^2G^2}$. And since, in general, if $b=\text{ta. B}$, $\text{sin. }x+b\text{ cos. }x=\surd(1+b^2)\text{ sin. }(x+\text{B})$; $\text{sin. }(x+\text{B})$ being $=\text{sin. }x\text{ cos. B}+\text{sin. B cos. }x=\text{cos. B }(\text{sin. }x+\text{ta. B cos. }x)$, and therefore $\text{sin. }x+\text{ta. B cos. }x=\frac{\text{sin. }(x+\text{B})}{\text{cos. B}}=\text{sin. }(x+\text{B})\text{ sec. B}=\text{sin. }(x+\text{B})\surd(1+b^2)$: it follows that $\alpha\text{ sin. }Gt+\beta\text{ cos. }Gt=\alpha\left(\text{sin. }Gt+\text{arc ta.}\frac{\beta}{\alpha}\right)\surd\left(1+\frac{\beta\beta}{\alpha\alpha}\right)$; and $\alpha\surd\left(1+\frac{\beta\beta}{\alpha\alpha}\right)=\surd(\alpha^2+\beta^2)=\surd\frac{(GG-B)^2+A^2G^2}{([GG-B]^2+A^2G^2)^2}M=\frac{M}{\surd([GG-B]^2+A^2G^2)}$.

Corollary. If we put $M\text{ cos. }Gt$ instead of $M\text{ sin. }Gt$, we shall have $s=\alpha'\text{ sin. }Gt+\beta'\text{ cos. }Gt$; α' being $=\beta=\frac{AGM}{(GG-B)^2+A^2G^2}$ and $\beta'=-\alpha=\frac{B-GG}{(GG-B)^2+AAGG}M$, and $s=\surd(\alpha'^2+\beta'^2)\text{ sin. }\left(Gt+\text{arc ta.}\frac{\beta'}{\alpha'}\right)=\surd(\alpha^2+\beta^2)\text{ sin. }\left(Gt+\text{arc ta.}\frac{B-GG}{AG}\right)$.

Scholium 1. Supposing B to approach very near to G^2, a case very likely to occur in nature, because the effects which are produced, where it is found, will predominate over others, on account of the minuteness of the divisor; we may neglect the part of the denominator $(G^2-B)^2$, in comparison with A^2G^2, and the co-efficient determining s will then become $\frac{M}{AG}$, the extent of the vibrations being inversely as A the co-efficient of the resistance; and, indeed, when the whole force of the periodical vibration is expended in overcoming a resistance proportional to the velocity, it may naturally be imagined that the velocity should be inversely as the resistance. It follows also from the proposition, that in this case the arc ta. $\frac{AG}{B-GG}$ approaching to a quadrant, the greatest excursions of the periodical motion and of the free vibration will differ nearly one fourth of the time of a complete vibration from each other.

Scholium 2. Since s is a line, and B its numerical co-efficient, making it represent a force, and since sin. Gt is properly a number also, the co-efficient M, both here and in Theorem J, must be supposed to include another linear co-efficient, as μ, which converts the sine into a line, to be added to s, the distance from the middle point; that is, M must be considered as representing $B\mu$, in which μ is the true extent of the periodical change of the centre of suspension, and $B=\frac{2g}{l}$, as in other cases; so that M is $=\frac{2g}{l}\mu=32\frac{\mu}{l}$, and $\mu=\frac{Ml}{2g}=\frac{1}{32}Ml$.

Corollary. In order to obtain a more general solution of the problem, we may combine the periodical motion thus determined with the free vibrations, as computed in Theorem H, the different motions, as well as the resistances, being totally independent of each other; but the most interesting cases are those which are simply periodical, the free vibration gradually diminishing with the multiplier e^{-mt}, and ultimately disappearing.

THEOREM L. If there are several periodical forces, the equation $\frac{dds}{dt^2}+A\frac{ds}{dt}+Bs+M\text{ sin. }Gt+N\text{ sin. }Ft+\ldots=0$, may be satisfied by taking $s=\alpha\text{ sin. }Gt+\beta\text{ cos. }Gt+\alpha'\text{ sin. }Ft+\beta'\text{ cos. }Ft+\ldots=\frac{M}{\surd([G^2-B]^2+A^2G^2)}\text{ sin. }\left(Gt-\text{arc ta.}\frac{AG}{B-GG}\right)+\frac{N}{\surd([F-B]^2+A^2F^2)}\text{ sin. }\left(Ft-\text{arc ta.}\frac{AF}{B-FF}\right)+\ldots$

For, the equations expressing the space described being simply linear, the different motions and resistances are added or subtracted without any alteration of the respective relations and effects.

Scholium. A free vibration may also be combined with this compound periodical vibration, by means of Theorem H; but it will gradually disappear by the effect of the resistance.

Lemma. For the addition of the arcs a and b, beginning with the well-known equation $\text{sin. }(a\pm b)=\text{sin. }a\text{ cos. }b\pm\text{sin. }b\text{ cos. }a$, we have, by addition, $\text{sin. }(a+b)+\text{sin. }(a-b)=2\text{ sin. }a\text{ cos. }b$, and $\text{sin. }a\text{ cos. }b=\frac{1}{2}\text{ sin. }(a+b)+\frac{1}{2}\text{ sin. }(a-b)$. Then, if $c=b+90°$, $\text{cos. }b=\text{sin. }c$, whence $\text{sin. }a\text{ sin. }c=\frac{1}{2}\text{ sin. }(a+c-90°)+\frac{1}{2}\text{ sin. }(a-c+90°)$; but $\text{sin. }(x+90°)=\text{cos. }x$ and $\text{sin. }(x-90°)=-\text{cos }x$, consequently $\text{sin. }a\text{ sin. }c=\frac{1}{2}\text{ cos. }(a-c)-\frac{1}{2}\text{ cos. }(a+c)$.

Again, if $c = a - 90°$, $\cos. c = \sin. a$, and $\cos. c \cos. b = \frac{1}{2}$ sin. $(a + b) + \frac{1}{2} \sin. (a - b) = \frac{1}{2} \sin. (c + 90° + b) + \frac{1}{2} \sin.$ $c + 90° - b) = \frac{1}{2} \cos. (c + b) + \frac{1}{2} \cos. (c - b)$. Also, since os. $a \cos. b = \frac{1}{2} \cos. (a + b) + \frac{1}{2} \cos. (a - b)$, and sin. a in. $b = \frac{1}{2} \cos. (a - b) - \frac{1}{2} \cos. (a + b)$, we have, by subtrac-ion, $\cos. (a + b) = \cos. a \cos. b - \sin. a \sin. b$, and, by ad-lition, $\cos. (a - b) = \cos. a \cos. b + \sin. a \sin. b$.

Corollary. If $a + b = c$ and $a - b = d$, $\cos. c + \cos. d$ $= 2 \cos. \frac{c + d}{2} \cos. \frac{c - d}{2}$; and $\cos. d - \cos. c = 2 \sin. \frac{c + d}{2}$ os. $\frac{c - d}{2}$; also $\sin. a + \sin. b = 2 \sin. \frac{a + b}{2} \cos. \frac{a - b}{2}$; and in. $a - \sin. b = \sin. a + \sin. (-b) = 2 \sin. \frac{a - b}{2} \cos. \frac{a + b}{2}$.

Theorem M. The equation, $\frac{dds}{dt^2} + A \frac{ds}{dt} + Bs + R$ in. $Ft \sin. Gt = 0$, may be solved by taking $s = \alpha$ sin. $[F - G] t + p) - \beta \sin. ([F + G] t + q)$; α being

$$\frac{\frac{1}{2} R}{\sqrt{([(F - G)^2 - B]^2 + A^2 (F - G)^2)}},$$

$$\beta = \frac{\frac{1}{2} R}{\sqrt{([(F + G)^2 - B]^2 + A^2 (F + G)^2)}},$$

$= \text{arc ta.} \frac{B - (F - G)^2}{A (F - G)}$, and $q = \text{arc ta.} \frac{B - (F + G)^2}{A (F + G)}$.

For sincc $\sin. Ft \sin. Gt = \frac{1}{2} \cos. (F - G) t - \frac{1}{2}$ cos. $F + G) t$, the equation becomes $\frac{dds}{dt^2} + A \frac{ds}{dt} + Bs -$ $R \cos. (F + G) t + \frac{1}{2} R \cos. (F - G) t = 0$; whence we btain the solution by comparison with Theorcm K and its orollary.

ect. IV.—*Astronomical Determination of the Periodical Forces which Act on the Sea or on a Lake.*

In order to compute, by mcans of the theory which has een laid down in the two preceding sections, the primitive des of any sea or any portion of the ocean, we must com-are its spontancous oscillations with those of a narrow pris-iatic canal, situated in a given direction with respect to ıc meridian, which in general must be that of the greatest ngth of the sea in question, neglecting altogether the ac-ıal breadth of the sea, which, if considerablc, may require have its own distinct vibrations compounded with those f the length, each being first computed independently of ıe other. Now, supposing the time required for the prin-ipal spontaneous oscillation of the sea or lake to be known, e must find the length of the synchronous pendulum, and ıking $B = \frac{2g}{l} = \frac{32}{l}$, we must next find a series for ex-ressing the force in terms of the sine, or cosines of multi-le arcs, increasing uniformly with the time.

Now the forcc is measured, for the direction of the meri-ian of the spheroid of equilibrium, by sin. cos. z (Theo-m A), z being either the zenith distance or the altitude; d it is obvious that, when the canal is situated obliquely ith respect to the meridian of the spheroid, the inclination the surface, and with it the force, will be diminished as ıe secant of the obliquity increases, or as the cosine of the bliquity diminishes; so that the force will vary as sin. cos. *lt.* sin. *Az.* if the canal be in an easterly and westerly di-ection; or if it deviate from that direction in a given angle, sin. cos. *Alt.* sin. (*Az.* + *Dev.*): and it is obvious that is force will vanish both when the luminary is in the ho-zon, and when it is in the vertical circle, perpendicular to ıe direction of the canal; that is, if we consider the force acting horizontally on a particle at the middle of the length of the given canal; and the same force may be considered as acting vertically, with a proper reduction of its magnitude, at the end of the canal; for the horizontal oscillations at the middle must obviously follow the same laws as the vertical motions at the end.

The case, however, of a canal running east and west, admits a very remarkable simplification; and since it approaches nearly to that of an open ocean, which has been most commonly considered, it will be amply sufficient for the illustration of the present theory. For, in gencral, sin. *Az.* $= \frac{\cos. Decl. \sin. Hor. <}{\cos. Alt.}$, and the expression, sin. cos. *Alt.* sin. *Az.*, becomes in this case sin. *Alt.* cos. *Decl.* sin. *Hor.* $<$. But sin. *Alt.* = sin. (*Lat.*) sin. *Decl.* + cos. (*Lat.*) cos. *Decl.* cos. *Hor.* $<$, and calling sin. (*Lat.*) for the given canal L, and cos. (*Lat.*) L′, the force becomes L sin. cos. *Decl.* sin. *Hor.* $<$ + L′ $\cos.^2$ *Decl.* sin. cos. *Hor.* $<$. Now, sin. *Decl.* = cos. *Obl. Ecl.* sin. *Lat.* + sin. *Obl. Ecl.* cos. *Lat.* sin. *Long.*; and since $\cos. \varphi = 1 - \frac{1}{2} \sin.^2 \varphi + \frac{3}{8} \sin.^4 \varphi - \frac{5}{16} \sin.^6 \varphi + \ldots$, the truc value of cos. *Decl.* might be expressed, if required, by means of this series, and its second and fourth powers would in gencral be sufficient for the computation.

But it will be more convenient to suppose the sun and moon to move in the ecliptic, and the ecliptic to be at the samc time so little inclined to the equator, that the longitude may bc substituted for the right asccnsion; a substitution which will cause but little alteration in the common phenomena of the tides. Then, if the sun's longitude be $\odot$, and the moon's ☽, the horary angles t and t', and the sine of the obliquity of the ecliptic $œ$, we shall havc sin. *Decl.* = $œ \sin. \odot$, or $œ$ sin. ☽; and cos. *Decl.* $= 1 - \sin.^2$ *Decl.* $+ \frac{3}{8} \sin.^4$ *Decl.* $= 1 - \frac{1}{2} œ^2 \sin.^2 \odot + \frac{3}{8} œ^4 \sin.^4 \odot \ldots$, and sin. cos. *Decl.* $= œ \sin. \odot - \frac{1}{2} œ^3 \sin.^3 \odot + \frac{3}{8} œ^5 \sin.^5 \odot \ldots$; also $\cos.^2$ *Decl.* $= 1 - œ^2 \sin.^2 \odot$; whence the sun's force becomes $\mathrm{L} \sin. t \, (œ \sin. \odot - \frac{1}{2} œ^3 \sin.^3 \odot + \frac{3}{8} œ^5 \sin.^5 \odot \ldots) + \mathrm{L}' \frac{1}{2} \sin. 2t \, (1 - œ^2 \sin.^2 \odot) = \mathrm{L} \sin. t \left(œ \sin. \odot - \frac{1}{2} œ^3 \left(\frac{3}{4} \sin. \odot - \frac{1}{4} \sin. 3 \odot\right) + \frac{3}{8} œ^5 \left[\frac{5}{8} \sin. \odot - \frac{5}{16} \sin. 3 \odot + \frac{1}{16} \sin. 5 \odot\right]\right) + \frac{1}{2} \mathrm{L}' \sin. 2t (1 - \frac{1}{2} œ^2 + \frac{1}{2} œ^2 \cos. 2 \odot) = \mathrm{L} \sin. t \, (œ' \sin. \odot + œ'' \sin. 3 \odot + œ''' \sin. 5 \odot) + (\frac{1}{2} \mathrm{L} - \frac{1}{4} \mathrm{L}' œ^2) \sin. 2t + \frac{1}{4} \mathrm{L}' œ^2 \sin. 2t \cos. 2 \odot$; $œ'$ being $= œ - \frac{3}{8} œ^3 + \frac{15}{64} œ^5 \ldots$; or about ·3645; $œ'' = \frac{1}{8} œ^3 - \frac{15}{128} œ^5 \ldots = {·}0078$, and $œ''' = \frac{3}{128} œ^5 \ldots = {·}00002$, and $œ^2 = {·}1585$. But $\sin. t \sin. \odot = \frac{1}{2} \cos. (t - \odot) - \frac{1}{2} \cos. (t + \odot)$, and $\sin. 2 t \cos. 2 \odot = \frac{1}{2} \sin. 2 (t + \odot) + \frac{1}{2} \sin. 2 (t - \odot)$. Hence the sun's force becomes $S \left(\mathrm{L} œ' [\frac{1}{2} \cos. (t - \odot) - \frac{1}{2} \cos. (t + \odot)] + \mathrm{L} œ'' [\frac{1}{2} \cos. (t - 3 \odot) - \frac{1}{2} \cos. (t + 3 \odot)] + \mathrm{L} œ''' [\frac{1}{2} \cos. (t - 5 \odot) - \frac{1}{2} \cos. (t + 5 \odot)] + \frac{\mathrm{L}'}{2} (1 - \frac{1}{2} œ^2) \sin. 2t + \frac{\mathrm{L}'}{4} œ^2 [\frac{1}{2} \sin. 2 (t + \odot) + \frac{1}{2} \sin. 2 (t - \odot)]\right)$; and that of the moon may be expressed in the same manner, by substituting M, t', and ☽, for S, t, and $\odot$.

The effect of that part of the hydraulic resistance, which is proportional to the square of the velocity, must be expressed by an approximation deduced from the periodical character of the force, as depending on that of the primitive forces concerned; taking, however, the precaution to use such expressions only as will always represent this resistance in its proper character as a retarding force: for if we simply found for it an equivalent expression, denoting accurately the square of the velocity, this square, being always positive, would imply a force acting always in the same direction. Now, we have already seen (Theorem J, Cor. 3), that $\sin.^2 x$ may be considered, with respect to its principal effect, as equivalent to $\cdot 8484 \sin. x$: and if we neglect, in the determination of the resistance, the effect of the smaller forces, and compute only that of the principal terms $\frac{1}{2} \mathrm{L}' \sin. 2t$, and $\frac{1}{2} \mathrm{L}' \sin. 2t'$, we may call the velocities depending on these forces $S' \cos. (2t + s')$ and $M' \cos. (2t' + m')$; S' and M' representing not exactly the proportion of the primitive forces of the sun and moon, but that of the tides depending on their combination with the conditions of the given sea or lake. The resistance will then be as the square of $S' [\cos. (2t + s') + \cos. (2t' + m')] + (M' - S') \cos. (2t' + m')$; and when least, it will be $D (M' - S')^2$, and when greatest, $D (M' + S')^2$, the difference being $4DM'S'$; so that the difference may be sufficiently represented by $4DM'S' [\cos. (2t + s') + \cos. (2t' + m')] \times \cdot 8484$, or rather $\times (\cdot 8484)^2$, because the value of $\cos. t + \cos. t' = 2 \cos. \frac{t + t'}{2} \cos. \frac{t - t'}{2}$, which is to be squared, requires the reduction from 1 to ·8484 for each of its factors; and in this manner we obtain a perfect representation of the period and quality of the resistance, and a very near approximation to its magnitude.

It will, however, be still more accurate to consider the resistance thus determined as comprehended in the value of the co-efficient A, substituting for it, in the case of the solar tide, $A' = A + 2\cdot 88\, DM'$, and for the moon $A'' = A + 2\cdot 88\, DS' + \cdot 8484\, D (M' - S')$; this latter part expressing that portion of the resistance D which observes the period of the lunar tide, and which may therefore be considered as added to the resistance A for that tide only.

Hence, collecting all the forces concerned into a single equation, the expression will become $\frac{dds}{dt^2} + A'''' \frac{ds}{dt} + Bs + S \Big(\mathrm{L}\, \alpha' [\frac{1}{2} \cos. (t - \odot) - \frac{1}{2} \cos. (t + \odot) + \mathrm{L}\, \alpha'' [\frac{1}{2} \cos. (t - 3 \odot) - \frac{1}{2} \cos. (t + 3 \odot)] + \alpha''' [\frac{1}{2} \cos. (t - 5 \odot) - \frac{1}{2} \cos. (t + 5 \odot)] + \frac{\mathrm{L}'}{2} (1 - \alpha^2) \sin. 2t + \frac{\mathrm{L}'}{4} \alpha^2 [\frac{1}{2} \sin. 2 (t + \odot) + \frac{1}{2} \sin. 2 (t - \odot)] \Big) + M \Big(\mathrm{L}\, \alpha' [\frac{1}{2} \cos. (t' - \text{☽}) - \frac{1}{2} \cos. (t' + \text{☽})] + \mathrm{L}\, \alpha'' [\frac{1}{2} \cos. (t - 3 \text{☽}) - \frac{1}{2} \cos. (t' + 3 \text{☽})] + \mathrm{L}\, \alpha''' [\frac{1}{2} \cos. (t' - 5 \text{☽}) - \frac{1}{2} \cos. (t' + 5 \text{☽})] + \frac{\mathrm{L}'}{2} (1 - \alpha^2) \sin. 2t' + \frac{\mathrm{L}'}{4} \alpha^2 [\frac{1}{2} \sin. 2 (t' + \text{☽}) + \frac{1}{2} \sin. 2 (t' - \text{☽})] \Big) = 0$; and from each of these terms the value of the corresponding pair of terms in the value of s may be obtained independently, by comparison with the $M \sin. Gt$ or $N \cos. Gt$ of Theorem K, which gives us

$$\frac{(GG - B) \sin. Gt + AG \cos. Gt}{(GG - B)^2 + AAGG} M, \text{ and}$$

$$\frac{AG \sin. Gt + (B - GG) \cos. Gt}{(GG - B)^2 + AAGG} N, \text{ respectively.}$$

But without entering minutely into the effects of all the terms of the equation of the forces, it may be observed in general that their results, with regard to the space described, will not differ much from the proportion of the forces, except when their periods approach nearly to that of the spontaneous oscillation, represented by B. Thus, since $\frac{1}{2} \cos. (t - \odot) - \frac{1}{2} \cos. (t + \odot)$ is the representative of $\sin. t \sin. \odot$, and since these terms will afford results in the form $\frac{1}{2} \alpha \cos. (t - \odot) + \frac{1}{2} \beta \sin. (t - \odot)$, and of $\frac{1}{2} \alpha' \cos. (t + \odot) + \frac{1}{2} \beta' \sin. (t + \odot)$, and if we neglected the slight difference of α and α', which is that of $\left(1 - \frac{\odot}{t}\right)^2 - B$, and $\left(1 + \frac{\odot}{t}\right)^2 - B$, $\frac{\odot}{t}$ being $\frac{1}{365\cdot 254}$ only, we should have $\frac{1}{2}\alpha [\cos. (t - \alpha) - \cos. (t + \odot)] + \frac{1}{2}\beta [\sin. (t - \odot) - \sin. (t + \odot) = \alpha \sin. t \sin. \odot + \beta \cos. t \sin. \odot = \sin. \odot (\alpha \sin. t + \beta \cos. t)]$; which is the same as if we considered the effect of the force $\sin. t$ separately, and afterwards reduced it in the proportion of $\sin. \odot$. Hence it is obvious, that for all modifications of the forces greatly exceeding in their periods the period of spontaneous oscillation, the effects may be computed as if the forces were exempt from those modifications, and then supposed to be varied in the same proportion as the forces; but we cannot be quite certain of the magnitude of the error thus introduced, unless we know the exact value of B, which determines the time of spontaneous oscillation.

Considering, therefore, in this simple point of view, the correct expression of the force L sin. cos. *Decl.* sin. *Hor.* < + L′ cos.² *Decl.* sin. cos. *Hor.* <, or ½L sin. 2 *Decl.* sin. *Hor.* < + ½L′ cos.² *Decl.* sin. 2 *Hor.* <, we may observe that the phenomena for each luminary will be arranged in two principal divisions, the most considerable being represented by ½L′ cos.² *Decl.* sin. 2 *Hor.* <, and giving a tide every twelve hours, which varies in magnitude as the square of the cosine of the declination varies, increasing and diminishing twice a year, being also proportional to the cosine of the latitude of the place, and disappearing for a sea situated at the pole. The second part is a diurnal tide, proportional to the sine of the latitude of the given canal, being greatest when the luminary is farthest from the equinox, and vanishing when its declination vanishes.

From these general principles, an attentive student may easily trace for himself the agreement of the theory here explained, with the various modifications of the tides as they are actually observed. It however remains for us to inquire more particularly into the cause of the hitherto unintelligible fact, that the maximum of the spring tides in the most exposed situations is at least half a day, if not a whole day, later than the maximum of the moving forces.

Now it is easy to perceive, that since the resistance observing the lunar period is more considerable than that which affects the solar tide, the lunar tide will be more retarded or accelerated than the solar; retarded when the oscillation is direct, or when $G^2 - B$ is positive, and accelerated when it is inverted, or when that quantity is negative; and that in order to obtain the perfect coincidence of the respective high waters, the moon must be farther from the meridian of the place than the sun; so that the greatest direct tides ought to happen a little before the syzygies, and the greatest inverted tides a little after; and from this consideration, as well as from some others, it seems probable that the primitive tides which affect most of our harbours are rather inverted than direct.

If we wish to apply this theory with precision to the actual state of the solar and lunar motions, we must determine the value of the co-efficients, from the tables of those luminaries. And, first, making the unit of time a whole solar day, in which the horary angle t extends from 0° to 360°, the sun's mean longitude $\odot$ will be $\frac{t}{365\cdot 254}$ added to the longitude at the given epoch, and the moon's approximate horary angle t' will be found from the variation, or the moon's age in space.

Now, in Burckhardt's Tables, p. 87, we find the variation for the midnight ending 1823, by adding the constant quantity 9° to the epoch for 1824, and (11ˢ· 14° 44′ 44″) + 9° = 11ˢ· 23° 44′ 44″, or — (6° 15′ 16″), according to the time of Paris. The movement for 12 hours is 6° 5′ 43″; consequently at noon, or 1824 Jan. 1, 0h. astronomical time at Paris, the variation is — (9′ 33″), corresponding to the movement of 18ᵐ· 49ˢ· in mean time, and the mean conjunction will take place at 18ᵐ· 49ˢ· Parisian time, which may be more compendiously expressed by calling it the true mean noon, in the time of the island of Guernsey or of Dorchester; and the movement in 24 hours being 12° 11′ 26·5″ = 12·19°, we shall have $t' = 360° - 12{\cdot}19° = 347{\cdot}81°$ when $t = 360°$, or $t' = \frac{347{\cdot}81}{360}t = {\cdot}96614t$; and the moon's horary angle, considered in relation to the circumference as unity, will always be ·96614t, if t be the number of days elapsed from the noon of 1st January 1814 at Guernsey.

The sun's mean longitude for the same epoch is (279° 35′ 23·1″) = ·77666; his longitude for any other time will therefore be ·77666 + ·002738t = ☉, and that of the moon ☽ = ·77666 + ·03386t.

We may compute, with sufficient accuracy, the effect of the modifications produced by the change of the moon's distance, or the inequality of her motion in her orbit, or of the periodical change of the inclination of her orbit to the equator, which takes place from the revolution of the nodes, by simply considering the changes which will be produced in the forces concerned by these inequalities, and supposing the effects simply proportional to their causes. If, however, it were desired to determine these modifications with still greater precision, we might deduce approximate formulas for expressing them from the elements employed in the Tables.

The epoch of the moon's mean anomaly for 1824 is (4ˢ· 29° 25′ 23·3″) + 2° = 151° 25′ 23·3″; the movement for 12ʰ· 18ᵐ· 49ˢ· is (6° 31′ 57″) + (9′ 47·9″) + 27″ = 6° 42′ 12″, which gives 158° 7′ 35″ for the mean anomaly at noon in the island of Guernsey. The daily movement being 13° 3·9′ = 13·065°, the mean anomaly will always be 158·127° + 13·065°t, reckoning t from the supposed epoch or day. The principal part of the central equation will then be, according to Burckhardt, 22692·4″ sin. $An.$, or (6° 18·2′) sin. (158$\frac{1}{8}$° + 13·065°t), and its sine will be very nearly ·11 sin. (13·065°t + 158·127°), which will represent the principal inequality of the longitude and of the variation, so that the variation, instead of 12·19°t, will become 12·19°t + 6·3° sin. (13·065°t + 158·127°), and this subtracted from 360°t, leaves 347·81°t — 6·3° sin. (13·065°t + 158·127°), the sine of which is nearly sin. 347·81°t — cos. 347·81°t ·11 sin. (13·065t + 158·127°).

The equatorial parallax is nearly 57′ + 187″ cos. $An.$, or 57′ + 3·1′ cos. (13·065°t + 158·127°); and the disturbing force, which varies as the cube of the parallax, or of 57′ [1 + ·0544 cos. (13·065°t + 158·127°)], may be expressed, with sufficient accuracy, by 1 + ·1632 cos. (13·065°t + 158·127°).

The supplement of the node for 1824 is (2·10·56) + 2′ = 70° 58′, to which we must add (3′·10·6″) t for the time elapsed; and the longitude ☽ will be 279° 35′ 23·1″ + (13° 10′ 35″) t.

Although the value of the co-efficient B is not directly discoverable, we may still obtain a tolerable estimate of its magnitude in particular cases, by inquiring into the consequences of assigning to it several different values, equal, for example, to the co-efficient of the solar or lunar tide, or greater or less than either; while we assume, also, for the co-efficient of the resistance, A, a great and a smaller value, for instance $\frac{1}{3}$ and $\frac{1}{10}$, supposing D to be inconsiderable. We then find, from the expression $\sqrt{(\alpha^2 + \beta^2)}\, M = \sqrt{(\alpha^2 + \beta^2)}\, B\mu$ (Theorem K, Schol. 2) $= \dfrac{B(S,M)}{\sqrt{[(GG - B)^2 + AAGG]}}$, for the solar tide, G being 1, if

$$\begin{array}{llllll}
B = & & \frac{1}{2}, & {\cdot}93442, & 1, & \text{or } 4; \\
\hline
A = & \begin{cases} \frac{1}{10}; \\ \frac{1}{3}; \end{cases} & \begin{matrix} -{\cdot}980, \\ -{\cdot}832, \end{matrix} & \begin{matrix} -7{\cdot}550, \\ -2{\cdot}742, \end{matrix} & \begin{matrix} 10, \\ 3, \end{matrix} & \begin{matrix} 1{\cdot}3324, \\ 1{\cdot}3252; \end{matrix}
\end{array}$$

and for the lunar, G being ·96614, and

$$A = \begin{cases} \frac{1}{10}; & -1{\cdot}122, \quad 10, \quad 8{\cdot}197, \quad 1{\cdot}3036, \\ \frac{1}{3}; & -\ {\cdot}913, \quad 3, \quad 2{\cdot}942, \quad 1{\cdot}2968, \end{cases}$$

respectively.

Hence it appears, that the resistance tends greatly to diminish the variation in the magnitude of the tides, dependent on their near approach to the period of spontaneous oscillation, and the more as the resistance is the more considerable; and supposing, with Laplace, that in the port of Brest, or elsewhere, the comparative magnitude of the tides is altered from the proportion of 5 to 2, which is that of the forces, to the proportion of 3 to 1, the multipliers of the solar and lunar tides being to each other as 5 to 6, we have the equation $\dfrac{36BB}{(1 - B)^2 + A^2} = \dfrac{25BB}{(n - B)^2 + A^2}$, whence we find that B must be either ·9380 or ·6328; and the former value making the lunar tide only inverse, we must suppose the latter nearer the truth; and the magnitude of the tides will become 1·663 and 1·998. And it appears from the same equations, that, n remaining = ·93442, A cannot be greater than ·632, and B would then be ·78540; and if $A = 0$, the values of B would be ·9617 or ·6091. It seems probable, however, that the primitive tides must be in a somewhat greater ratio than this of 2 to 1 and 5 to 3, when compared with the oscillations of the spheroid of equilibrium; and if we supposed $B = {\cdot}9$ and A still $= \frac{1}{10}$, we should have 7·071 and 9·756 for their magnitude. Now if $B = {\cdot}6328$, the tangents of the angular measures of the displacement, $\dfrac{\beta}{\alpha} = \dfrac{AG}{GG - B}$, become $\dfrac{1}{{\cdot}3672}$ and $\dfrac{{\cdot}96614}{{\cdot}30160}$ respectively, giving us 69° 50′ and 72° 40′ for the angles themselves; and if $B = {\cdot}9$, these angles become 45° and 70° 24′ respectively; the difference in the former case 2° 50′, and in the latter 25° 24′, which corresponds to a motion of more than twenty-four hours of the moon in her orbit.

It appears, then, that, *for this simple reason only*, if the supposed data were correct, the highest spring tides ought to be *a day later* than the conjunction and opposition of the luminaries; so that this consideration requires to be combined with that of the effect of a resistance proportional to the square of the velocity, which has already been shown to afford a more general explanation of the same phenomenon. There is indeed little doubt, that if we were provided with a sufficiently correct series of minutely accurate observations on the tides, made, not merely with a view to the times of low and high water, but rather to the heights at the intermediate times, we might by degrees, with the assistance of the theory contained in this article, form almost as perfect a set of tables for the motions of the ocean as we have already obtained for those of the celestial bodies, which are the more immediate objects of the attention of the practical astronomer. There is some reason to hope that a system of such observations will speedily be set on foot by a public authority; and it will be necessary, in pursuing the calculation, on the other hand, to extend the formula for the forces to the case of a sea performing its principal oscillation in a direction oblique to the meridian, as stated in the beginning of this section.

For such a sea, the calculations would be somewhat complicated, except in the case of its being situated at or near the equator. We should then obtain, by proper reduction, for the volume of the force, putting D the sine of the duration, or of the angle formed by the length of the canal with the equator, and D' its cosine, the expression $D \sin. \cos. \, Decl. \cos. \, Hor. < + D' \cos.^2 Decl. \sin. \cos. \, Hor. <$; and the order of the phenomena would be less affected by the alteration of the situation of the canal than could easily have been supposed, without entering into the computation. This expression, when $D = 0$, becomes, as it ought to do, identical with the former, making $L = 0$. (L. L.)

The preceding theoretical part of this article is that which the late Dr Thomas Young contributed to the Supplement to the former edition of this work, nearly at the time when the concluding volume of the *Mécanique Céleste* appeared, treating on the same subject. But we presume that, on a close examination, Dr Young's mode of investigation will be found to be of a far more elementary and intelligible description than that of Laplace; and not only so, but it accords much more closely with the phenomena, without requiring the aid of certain very questionable assumptions, which are indispensable in the method followed by this illustrious foreigner. Indeed, under so many different aspects had Dr Young at one time or another studied the subject, that even in his earlier writings are to be found some of the speculations on the tides, which have recently been advanced as entirely new. But in his time, as he was well aware, the real facts recorded and published were so scanty, and the rest so uncertain, that he had no proper data on which to speculate with confidence.

Considering how important it must be for the purposes of navigation and commerce that the tides should be predicted with some degree of certainty, it might have been expected, that when once Newton had furnished a satisfactory mode of explaining in a general way the phenomena of the tides, attention would immediately have been directed, in the maritime parts of all civilized countries, to obtain if possible such an acquaintance with the actual state of the tides as might, with the aid of theory, have served for predicting them, at least approximately. So far, however, were Newton's speculations from being immediately followed up by extensive and accurate observations in every trading port, that during a whole century which succeeded to his time, the subject had been most unaccountably neglected, observations having been made in but very few places, and those only during portions of that long period; nor had any proper efforts been made to deduce from them so much as the empirical laws of the tides. Thus it was only in 1829 that the very general interest which is now taken in the subject may be said to have commenced, with Mr Lubbock's examination of the tide observations which are regularly made and recorded at the London docks. The discussion of these he undertook with the view of obtaining correct tables for predicting the time and height of the tides for the British Almanac. When, however, the principal inequality of the tides, the half-monthly or semimenstrual inequality, had been determined with sufficient accuracy for practical purposes, the further researches in this difficult problem could not have been so soon undertaken, but for the interest felt in the subject by some other distinguished men of science, particularly by Mr Whewell, and for the pecuniary assistance afforded by the British Association.

The publication of the above-mentioned researches of Mr Lubbock in the Philosophical Transactions for 1831, drew the attention of mathematicians as well as of navigators to the subject of the tides; but it was Mr Whewell who aroused more general interest, and, assisted by the Admiralty, engaged the co-operation of observers in various parts of the world. The subject is well deserving the attention and assistance of every enlightened maritime and commercial nation; for, to do it justice, the study of the tides ought to be pursued in the same manner as that of the other provinces of astronomy; that is, constant and careful observations of the phenomena should be made, reduced, and discussed, at the public expense, so as both to test the accuracy of the tables already framed, and to supply the means of rendering them still more accurate. In this manner also any new corrections, and any changes in the elements of the old corrections, would be brought into view as soon as there were evidence of their existence. Till the problem of the tides is thus treated in a manner worthy of its scientific importance, and of the promise which it now holds forth, it must be regarded as a blot in that system of the national cultivation of astronomy, of which our public observatories afford, in other departments of that science, such effective and magnificent examples.

Mathematicians have not yet succeeded in referring the phenomena of the tides to mechanical principles by rigorous reasoning; and, considering the difficulties of the subject, there is reason to suppose it will be some time before this problem can be fully solved. In the mean while we have an intermediate type of comparison in the equilibrium theory of Daniel Bernoulli, as given in his treatise *Du Flux et Reflux de la Mer*; for, by modifying the epochs and other elements which enter into the formulæ furnished by that theory, these may be made to represent in an approximate manner the laws of the phenomena.

The equilibrium theory supposes, that if the earth were a perfect sphere completely covered by water, this fluid would assume the same form at any given instant as it would do if the forces then acting upon each particle were invariable in magnitude and direction. Although our globe, being only partially covered by water, does not admit of this system accurately taking place, the distribution of the land is such as to allow a closer approximation to it in the southern hemisphere than in northern latitudes and on our coasts; so that if we further suppose the tide-wave nearly to follow such a law at the Cape of Good Hope, or in some still more southern region, and that it is thence propagated northward along the Atlantic Ocean, and round our island, preserving all the while a certain proportion of the magnitude and velocity which it had when first formed under the action of the sun and moon; then, upon these suppositions, which are virtually those of Bernoulli, formulæ may be framed which will admit of being adjusted by comparison with observation, so as to express the variations in the time and height of high water at any given place, if the time in which the tide-wave is propagated do not vary. But although to a certain extent this equilibrium theory seems thus to suggest and express the laws of the various inequalities of the tides, it must not be rated above its value. It is not the true theory, but a very inaccurate and insufficient substitute for it, which we are compelled to adopt in the present imperfect state of the science of hydrodynamics. The tides are a problem of the motion, not of the equilibrium, of fluids; and we can never fully explain the circumstances of the phenomena till the problem has been solved in its genuine form. Mr Whewell however thinks it is not too much to expect that it may hereafter be rigorously shown from mechanical principles, that the form of an irregular fluid mass constantly dragged along by certain forces, shall at every instant resemble the form of equilibrium which the forces would produce at some anterior epoch, the anterior epoch being somewhat different for the different features of the fluid form. If such a hydrodynamical proposition could be established, almost all the facts hitherto discovered respecting the tides would be fully explained.

In the able article by Mr Lubbock, we have the first accurate comparison of Bernoulli's theory of the tides, with the results of observation as deduced from a period of nineteen years in the port of London. The results are important, not merely as furnishing materials and general rules for constructing tide-tables, but also for their general accordance with the theory in question, particularly as regards the semimenstrual inequality. This agreement was the more important, as affording the indication of a sort of physical connection between that theory and observation, and consequently as justifying such a further examination of its consequences as might lead to the discovery or suggestion of such modifications as would conduce to its general accordance with the laws of all the facts observed. In a subsequent discussion of the tides of Liverpool, in the Phil. Trans. for 1835 and 1836, Mr Lubbock found further evidence in favour of the sort of law to which we have already alluded, and which had indeed been previously suggested by Mr Whewell in his papers on the tides of London and Liverpool; that by referring the tide, not to the lunar transit immediately preceding, but to a transit anterior to the tide by one, two, or more days, the formulæ furnished by the equilibrium theory of Bernoulli would be brought into a very near accordance with the observed inequalities in the heights and times of the tides which are due to the changes in the moon's parallax. This was in some respects an important step, particularly as affording convenient expressions for the corrections, since it has been found to apply to a considerable extent to all the periodical inequalities, and seems to be in conformity with the idea that the tides are primarily generated in the Southern Ocean, and thence reach our coasts in the derivative form only. But in one respect it is not satisfactory; for even at the same place very different anterior epochs are required for the several inequalities. Thus, though each formula furnished by the theory can be separately adjusted by trial to represent generally the results of observation for one particular correction at any assigned station, yet since, in the several expressions, the same symbol requires a different value for almost every different correction, such formulæ cannot consistently represent the laws of nature; so that Bernoulli's theory, even when thus modified, is quite incompetent to assign any physico-mathematical reasons for the adjustments in question. The complete solution of the problem would therefore probably require a far more thorough knowledge of the laws of hydrodynamics.

Mr Whewell's researches, on which he has now published a dozen papers, have been chiefly directed to the three following points; first, the motion of the tide-wave at different parts of the ocean; secondly, the comparison of the observed laws at certain places with the theory; and, lastly, the laws of the diurnal inequality of the tide, which seem the most intricate of all. His first memoir, entitled an "Essay towards a first Approximation to a Map of Cotidal Lines," appeared in the Phil. Trans. for 1833. By a cotidal line is meant such as may be drawn through all those points of the ocean which have high water simultaneously. The cotidal line for any hour may be considered as representing the summit or ridge of the tide-wave at that time; meaning by the tide-wave, that protuberance of water upon the surface of the ocean which moves along the seas, and by its motion brings high water and low water to any place at the time when the elevated and the depressed parts of the watery surface reach that place. The cotidal lines for successive hours represent the successive positions of the summit of this wave; so that if a spectator were detached from the earth to perceive the summit of the wave, he would see it travelling round the earth in the Southern Ocean once in twenty-four hours, accompanied by another at twelve hours distance from it, and both sending branches into the narrower seas; and the manner and velocity of all these motions will be assigned by means of a map of cotidal lines. By analysing the movements of the tides according to the most simple considerations of the laws of fluid motion in open seas and in channels, and by explaining the circumstances of their convergence or divergence, their interference with each other, their retardation in shallow water, and their consequent tendency to sweep around the coasts, and to approach them almost perpendicularly; and further, by discussing very carefully all the materials with which nautical surveys and books of navigation could furnish him, Mr Whewell was enabled to construct a map, which not only represented the general circumstances of the tides of the coasts of Britain, but likewise, as he supposed, of the movement of the great tidal wave from the Southern Ocean to the coasts of Europe through the Atlantic; as also its progress in the Indian Seas, and on the coasts of New Zealand.

In order to correct his first approximation to a map of cotidal lines, the British Association, at the instance of Mr Whewell, procured a very extensive series of observations to be made on the coasts of Britain and Ireland, at 537 stations of the coast-guard, in June 1834. These were not only repeated in June 1835, but simultaneous observations were also made, at the request of our government, by the other great maritime powers of Europe and North America. The chain of places of observation extended along the coast of North America, from the mouth of the Mississippi, round the keys of Florida, and northward as far as Nova Scotia; and along the shores of Europe, from the Straits of Gibraltar to the North Cape of Norway. The number of stations was, twenty-eight in America, seven in Spain, seven in Portugal, sixteen in France, five in Belgium, eighteen in the Netherlands, twenty-four in Denmark, and twenty-four in Norway; and observations were made by the coast-guard of this country at 318 places in Britain, and at 219 in Ireland. The observers were directed to record the times of high and of low water, and the height of the surface at each of these times, measured from a fixed point. At each place, the differences between the time of high water, and the time of a preceding transit of the moon, which differences Mr Whewell calls the lunitidal intervals, were taken for the whole series of observations. The immense mass of observations thus furnished was reduced under Mr Whewell's directions; and some of the results, which are extremely important and interesting, have been published in the Phil. Trans. for 1835 and 1836. The last of these publications is accompanied by a second map of the cotidal lines of the coasts of Europe, and by a chart, which shews, by means of a peculiar notation, the range, in yards, of the spring tides at the different stations of observation.

Among other remarkable conclusions which have resulted from these observations, may be mentioned the rotatory motion of the tide-wave, which, entering the German Ocean between the Orkneys and Norway, sends a southerly detachment along the coasts of Britain, which is reflected from the projecting coast of Norfolk upon the north coast of Germany, and meets the tide-wave again on the coast of Denmark. Owing to this interference of different tide-waves, the tides are almost entirely obliterated on the coast of Jutland, where their place is supplied by nearly perpetual high water. Indeed this must always be the case wherever one tide-wave continually arrives about six hours later than another, or where more tide-waves successively arrive at still shorter intervals.

Mr Whewell's second object was to compare the observed laws of the tides with the theory, or to propose such modifications of the forms of the theory as would reconcile it with observations. In his very ingenious memoir "On the Empirical Laws of the Port of London," he attempts to deduce from observation, and from very simple considerations, the character of the formulæ for determining the establishment, the semimenstrual inequality, the corrections for lunar and solar parallax and declination, both as affecting the times and the height of high water. His papers on the "Empirical Laws of the Tides of the Port of Liverpool," and on the "Solar Inequality and Diurnal Inequality" of the tides at the same place, are full of valuable suggestions, which the subsequent investigations of Mr Lubbock have in some cases very remarkably confirmed and extended. Several of the last of Mr Whewell's papers relate to the constancy of the half-tide level, and the diurnal inequality of the heights and intervals of the times of the tide. The discussion of the Liverpool observations had exhibited this last, though under circumstances much less striking than those which characterize its appearance at other places, as will be noticed more particularly afterwards. His first memoir on this subject relates to the diurnal inequality at Plymouth and Sincapore; at the last of which places its magnitude is very remarkable, making a difference of not less than six feet in the height of the morning and evening tides, and quite sufficient to obliterate, under certain circumstances, one of the semidiurnal tides, and explaining certain peculiarities in the phenomena which have hitherto been considered as cases of interference.

The researches of Mr Lubbock and Mr Whewell on the tides, and their discussions of the observations made at various ports, have now reached such an extent as to be distributed through ten successive volumes of the Phil. Trans. (1831–1840). Some shorter articles have been also published in the Reports of the British Association, and abstracts in the Philosophical Magazine and other journals. Mr Lubbock has besides published a small Elementary Treatise on the Tides. Before these gentlemen took up the subject, which they have done with great credit to themselves and advantage to the public, the theory of the tides, though little cultivated and little known, was in advance of observation. Tide-tables were constructed by unpublished rules, which, though generally very imperfect, formed a profitable possession to those to whom they were known; and the distinctive characters of the tides in the different ports of this kingdom, that of Liverpool perhaps excepted, were confined to the experience and tact of those who were accustomed to use them; but how different is the case at present. The rules for the construction of tide-tables are not only public property, but are based upon the most extensive observations; laws whose existence was hardly suspected, are now distinctly laid down; the progress of the waves in the most frequented parts of the ocean is beginning to be accurately developed; theory, which formerly was in advance of observation, though greatly improved in those parts of it which do not involve the hydrodynamical laws of the ocean, is now greatly behind it; and such a basis of facts has been laid down as may enable the mathematician to commence such a series of investigations as may terminate in enabling some one to give to the theory of the tides a form more closely resembling, in the certainty of its predictions, the almost perfect theory of physical astronomy.

Inaccuracy of tide records.

Mr Lubbock and Mr Whewell have, among other subjects, treated at considerable length on the causes of inaccuracy in tide records and observations. We shall here endeavour to notice the chief of these; and it will serve two purposes if we give a popular account of them, in connection with the principal empirical corrections which these gentlemen have found requisite to compensate for the various inequalities of tidal phenomena. On comparing the times of the tide at different places, as hitherto stated by the best authorities, we find very many cases which seem quite incompatible with any notion of obvious continuity and simple laws prevailing in this class of facts. For instance, if the time of high water at Plymouth were five o'clock, and at Eddystone eight, as usually stated, the water must be falling for three hours on the shore, while it is rising at ten or twelve miles distance, and this through a height of several feet. It is difficult to conceive how any elevation at the one place should not be transferred to the other in a much shorter time. In fact, eight o'clock, instead of being the time of high water at Eddystone, is the time of slack water, or when the current changes. Thus there is reason to think that very many, if not the whole, of such inconsistencies have originated in confounding two different phenomena, namely, the time of high water, and the time of the change from the flow to the ebb current. In some cases the one, and in some cases the other, of these times has been recorded as the hour of the tide. The time of slack water, or of the change of current, only coincides with the time of high water very near the shore, and within its influence, and especially in harbours which have only one opening. The difference between these times is generally considerable, and great confusion has arisen from not properly distinguishing between them. The persuasion, that in waters affected by tides, the water always rises while it runs one way, and falls while it returns in the opposite direction, though very erroneous, has long been quite general. For example, it has been usual to state that the time of tide in the British Channel must be three hours later in the mid sea than near the shore, because the current continues running eastward three hours after the time of high water on the coast. Many instances could be given of the perplexities which have arisen from this assumption.

The times most usually recorded as the tide-hours for different places, are those of the tides on the days of new and full moon; which times are often called the establishments of the places to which they belong, and are supposed to regulate the times of the tide on all other days of the lunation, because the tide is primarily governed by the moon. This, however true as a first approximation, assumes that the tide always occurs at the same hour-angle from the moon. But the hour of the tide on any day expresses its hour-angle from the sun; and as the moon changes her right ascension by about forty-eight minutes every day, the observed hour of the tide being given on the day of full and new moon, the hour-angle from the moon may be different according to the time of the day when the conjunction takes place, compared with the time of the observed tide. Thus, if the conjunction take place at one o'clock in the morning, and the observed tide at eleven at night, the distance of the tide from the sun is eleven hours; but at eleven at night the moon is to the east of the sun by her motion in twenty-two hours, which is forty-four minutes of hour-angle, and therefore the tide is only ten hours sixteen minutes behind the moon. But if the observed tide occur at one in the morning, and the conjunction at eleven at night, the moon, at the time of the tide, is forty-four minutes to the west of the sun, and the tide occurs at one hour forty-four minutes. In the former case the establishment is forty-four minutes less, in the latter forty-four minutes more, than the observation of the hour of the tide gives it. If the observed hour of tide were six in the evening, and the conjunction occurred at one in the morning, the true establishment would be $5^{h.}\ 26^{m.}$; but if the tide be at six in the morning, and the conjunction at eleven at night, the true establishment will be $6^{h.}\ 34^{m.}$ Thus, an observation of the hour of the tide on the day of new or full moon leaves an uncertainty of at least $1^{h.}\ 8^{m.}$ as to the establishment, if we do not take into account whether the morning or afternoon tide was observed, and at what hour the conjunction or opposition of the moon took place. Besides, the time of high water may often be doubtful to the extent of ten or fifteen minutes, from inaccuracy in the observation; and as this error may occur in opposite directions at two different observations, and may be combined with that of the observation just mentioned, we may thus have two establishments, differing above a hour and a half, and yet collected from observations at e same place.

In the determination of the establishment little accuracy to be expected, unless numerous observations be used; d in this case, the mean of the morning and evening tide-urs may be taken, the effect of the intervals by which the njunctions and oppositions of the moon precede and suc-ed noon being supposed to compensate each other. But en the establishment is to be collected from only a few servations, it will be proper to calculate in each case the nitidal interval or hour-angle by which the tide is distant m the moon.

The time of high water does not follow the moon's transit the same interval at every period of the lunation; on the contrary, this lunitidal interval is sometimes greater and sometimes less than that corresponding to the new and full moon, and is regulated by the distance of the moon from the sun. The difference between this and the mean interval is called the half-monthly or semimenstrual inequality. When the moon and sun are in conjunction, the corresponding tide follows the moon by its mean interval. When the moon is at various hour-angles after the sun, the following are the mean corrections of the mean interval, negative and positive. But the law and magnitude of such numbers depend on the relative effect of the sun and moon upon the tides: the amount is different at different places, and varies with the declinations and parallaxes of the luminaries.

Hour-angle of the moon........	0,	1,	2,	3,	4,	5,	6,	7,	8,	9,	10,	11,	12 hours.
Correction of establishment...	0,	—16,	—31,	—41,	—44,	—31,	0,	+31,	+44,	+41,	+31,	+16,	0 minutes.

hus, if the establishment corresponding to the new and ll moon be six hours, the time of the high water, when e moon is one hour from the sun, will be 5h. 44m. after e moon's transit; when the moon is two hours from the n, the time of tide will be 5h. 29m. after the transit; and on. When the moon is six hours from the sun, the cor-sponding time of high water will again coincide with the ean, after which the lunitidal interval will exceed the ean, till the next conjunction or opposition, and then the me cycle recurs. Hence if the establishment were col-cted from any observation of the tide not corresponding the day of new or full moon, it would be liable to an error. the establishment were six hours by an observation made en the moon's hour-angle was four hours, and compared th the time of the moon's transit, it would appear to be 16m.; but by an observation made when the moon's hour-gle was eight hours, it would appear to be 6h. 44m. This fference in the results would be avoided by taking the e which corresponds to new or full moon, or by applying e proper correction according to the preceding table when y other tide was observed. Some authors make this cor-ction depend on the day of the moon's age; but as this is very inaccurate mode of determining the angular distance the sun and moon, the proper way is to make the cor-ction depend on the difference of right ascensions of the n and moon, that is, on the time of the moon's transit pressed in apparent time as above. The chance of error ould be removed more effectually by taking the mean of the intervals between tide and transit, during a half lu-tion, or any whole number of half lunations.

Although, according to theory, the semimenstrual ine-ality of the time depends on the ratio of the force of the oon to that of the sun, yet the observations shew it to be fferent at different places. The total amount of this ine-ality, that is, the difference between the greatest and least nitidal intervals, is 95 minutes at Plymouth and 93 at istol, which exceed its values at many other places. It 90 minutes at London and Sheerness, 86 at Liverpool d Howth, 84 at Leith, 83 at Portsmouth and Pembroke, at Ramsgate, and only 80 at Brest. Each of these is termined from observations so numerous as to be certain thin a minute or two. We see, therefore, how different e mass of the moon would be found to be when deduced m the observations of different places; so that the near reement of the mass deduced by Laplace from the tides Brest, with the mass obtained from other phenomena, ust have been merely accidental; and this also puts an d to all attempts to correct the tables of the tides by eans of the mass of the moon.

The semimenstrual inequality of the height of the tides, en compared at different places, gives a similar result. is not, however, the actual amount of this inequality, but proportion to the mean tide, that is to be taken. At rtsmouth, the mean range of the tide is 12·5 feet; the total semimenstrual inequality, or difference between the high waters at neap and spring tides, is 2·5 feet; that is, only $\frac{1}{5}$th of the mean tide. But at Plymouth, where the mean tide is also 12·5 feet, the total semimenstrual inequality is 3·4 feet, and thus the fraction is $\frac{1}{3{\cdot}4}$. At Bristol, again, where the mean range of the tide is 33 feet, the semimenstrual inequality is 10 feet, or $\frac{1}{3{\cdot}3}$ of the mean tide. In tide records, as formerly kept, it is often uncertain whether the height marked, mean that of the stream tide, or only the high water on the days of new or full moon.

From the general observations made simultaneously in Europe and America in June 1835, it appears that the amount of the semimenstrual inequality of the time is very different at different parts of the world; and though these observations were of too rude a kind to give the amount of the difference, they are sufficient to prove its existence; especially when coupled with a reason for the difference, namely, that the spring tides being higher than the neaps, the tides of the two kinds may travel with velocities which at different places have different relations. Mr Whewell conceives that the observations afford evidence of a local as well as a general semimenstrual inequality. The changes of this inequality are not obviously explicable. On the coast of North America, the amount of the difference of the greatest and least lunitidal intervals is small, being generally less than 80 minutes, and at Newport as low as 56. On the coast of Portugal, at several places, this difference is so small as almost to throw doubt on the accuracy of the observations. At Pera in Algarve it is only 42, at Lagos Bay 24, while at Peniche it is 130. On the greater part of the French coast it ranges with great steadiness from 80 to 100, except at the little harbour of Abrevrak, where it is 125 minutes. At Torr Head, on the north coast of Ireland, it is 146, and at Rachlin Island 240; but these are cases of extreme irregularity. On many parts of the south coast of England it is small, being from 70 to 74, as at Exmouth, Weymouth, St Alban's Head, St Lawrence, Swanage Bay, Brighton, and Hastings.

From the same observations, it appears that the amount of the semimenstrual inequality of the height also varies. In general, the greatest range is twice or twice and a half the smallest; but this is so far from being a universal rule, that many of the cases which at first seem to agree with it, really differ widely when allowance is made for the diurnal inequality. Thus, at Mount Desert Island, near the coast of America, the whole amount of the semimenstrual inequality of high water is about three feet in a tide of thirteen feet, thus reducing the smallest range to eleven; but the diurnal inequality reduces it further to eight feet.

If, as is generally believed, the most of the tides be ge-

Correction for age of the tide.

nerated in the Southern Ocean, the tide which is produced under the more immediate influence of the new or full moon cannot, at most places, be that which takes place on the day of new or full moon; and in reading the preceding sketch of the phenomena, these must not be confounded. The latter, however, is that which has commonly been observed for the purpose of determining the establishment; but it often differs materially from the former, and in the tide-records anomalies frequently occur which seem referable to this difference. It has already been mentioned, that the agreement between the empirical laws of the tides and the equilibrium theory is much improved, by referring the tides to a transit anterior to their occurrence by two or three days. To illustrate this, Mr Lubbock denotes the successive transits of the moon (at intervals of about twelve hours) by the letters A, B, C, D, E, F; F being the transit which immediately precedes, by about two hours, the high water at London: and he finds that the laws of the tides at London and Liverpool agree best with theory when they are referred to the transit B. The tide which reaches London at two hours after the transit F, was at Plymouth about six hours after the transit E; and as from transit B to transit E is about thirty-eight hours, if we refer the Plymouth tides to B, we take a transit about forty-four hours before the tide. Transits A and C are about fifty-six and thirty-two hours anterior to the tide. Nearly the same may be said of Bristol. The general result is, that the transit B gives the best tables.

We cannot, however, in this way completely reconcile observation and theory, even as regards the semimenstrual inequality. From Mr Lubbock's researches on the Liverpool tides (Phil. Trans. 1836, p. 57), it appears, that while the transit A very nearly reconciles the theoretical and observed times, we must take a still earlier transit if we would obtain the like agreement in the heights. Nor does that selection of a transit which best represents the semimenstrual inequality bring about an agreement with theory in the parallax and declination corrections. Hence, although there appear to be in the actual laws of the tides inequalities *corresponding* to all those which arise from the supposition of the equilibrium tide of an anterior epoch transmitted along the ocean to our shores, we cannot so assume the epochs to produce all the inequalities at once even for the same place. The epoch is of one value for the times, of another for the heights; different for the parallax correction, and again for the effect of declination.

The relation between a change in the epoch and the semimenstrual inequalities may be examined as follows. The successive lunar transits occur at intervals of about twelve hours twenty-four minutes of solar time. The semimenstrual inequality, both of interval and of height, is referred to the solar time of the moon's transit. The height is the same whether it be referred to the transit E immediately preceding, or to the transit B a day and a half sooner. If the moon moved uniformly in her orbit, the inequality of the interval between the tide and transit would be the same, whether the tide were referred to the transit E, or any anterior one, as B; for the interval is increased by the constant quantity twelve hours twenty-four minutes nearly for every transit that we go back. But though the inequality of the interval for any given tide would be the same, it would not occupy the same place in the table or curve, since it would be referred to a different hour of the transit. For example, if the mean interval of transit and tide at Bristol referred to E be $7^{h.}$, and if, when the moon's transit is $2^{h.}$, the tide be at $8^{h.}$, the interval is $6^{h.}$, and therefore in this case the inequality is minus one hour. If now we refer this tide to the transit B a day and a half sooner, the interval of the transit and tide will be $6^{h.} + 36^{h.} + 72^{m.}$, and the mean interval will be $7^{h.} + 36^{h.} + 72^{m.}$; and therefore, as before, the inequality is minus one hour. But the moon's transit E taking place at $2^{h.}$ solar time, the transits D, C, B will take place at $1^{h.}\ 36^{m.}$, $1^{h.}\ 12^{m.}$, $0^{h.}\ 48^{m.}$ respectively; and therefore the inequality of minus one hour, which was referred to the transit happening at $2^{h.}$ when transit E was used, is referred to the transit at $0^{h.}\ 48^{m.}$ when we employ the anterior epoch B. Thus, by referring to an anterior epoch, the whole semimenstrual inequality is shifted backward through twenty-four minutes of lunar transit, for every step of one transit backwards. This is the mean result, supposing the moon's motion uniform, and neglecting all other inequalities; on which suppositions nothing would be gained or lost in accuracy by the change of the epoch. But in the actual case, this mean result is modified by the influence of the other inequalities, which make one transit a better epoch than another.

The tide which comes to the shores of narrow and long seas is not immediately produced by the luminaries, but is derived from the tide in the main ocean. Its circumstances are governed by those of the primary tide from which it is derived; and whatever interval may elapse during its transfer, it is regulated by the position which the sun and moon had at the time when they determined the primary tide. Now this time may have been one, two, or more days before the tide reaches the place where it is observed. Thus the tide on the shores of North America and Spain, conformably with its being supposed to be generated in the Southern Ocean, and sent up the Atlantic, seems to correspond to the configuration of the sun and moon at a day and a half previous. The tide in the port of London appears to be two days and a half old when it arrives. The time spent in the transfer of the tide is very different in different parts of the world, and has not yet been ascertained for many places. But it affects the determination of the establishment from observations, in a manner which may be thus explained. If the tide at London be determined by the position of the sun and moon two and a half days before it occurs, the moon must then have been more to the west of the sun by an angle of two hours (her motion in Æ in two and a half days) than she is when the tide arrives. Hence the tide which happens on the day of full moon, corresponds to the period when the moon was in Æ, two hours west of the point opposite to the sun, or ten hours east of the sun. Therefore, by the preceding small table, the tide is thirty-one minutes later than the mean interval between the tide and moon's transit. The tide at London takes place nearly at two o'clock on the days of new and full moon; and therefore $1^{h.}\ 29^{m.}$ is the corrected establishment for London.

The establishment is usually defined to mean the hour of high water at new and full moon. Mr Whewell calls this the vulgar establishment. Observations of tides have most commonly been made with the view of determining this vulgar establishment, which it now appears is not a corresponding quantity at different places. The mean of all the lunitidal intervals for a half lunation, he calls the corrected establishment. Hence the vulgar establishment seems to be greater than the other by a quantity depending on what Mr Whewell calls the age of the tide; namely, the length of time which has elapsed since its real or theoretical origin. This is also what Mr Lubbock, following Bernoulli, calls the *retard*. It is considered as the principal reason why the greatest tides do not occur on the days of new and full moon, nor the least at the quadratures, but one, two, or more days after. Both Mr Lubbock and Mr Whewell frequently use the term epoch in the same sense as the age of the tide, or at least as the time during which any particular inequality has been transferred from the Southern Ocean to the place of observation.

The doctrine of the age of the tide, as thus laid down, not unfrequently leads to inconsistencies, some of which are only apparent, being referable to the mixture and interference of different tides; but another reason for some of them, we presume, is, that the luminaries, after generating the primary tides, are not, as they are usually assumed to be, mere idle spectators of the derivative tides, but often continue to act upon them in various ways, accelerating some and retarding others.

Although the observations make the parallax corrections both of height and time vary as the parallax, yet some of the observations do not make the height of the tide itself proportional to the cube of the parallax, as theory requires, but make it more nearly proportional to the square of the parallax, being as the 2·2 power. The declination corrections both of height and time are found by observation to vary as the square of the sine of the declination, which, according to theory, they should do.

But the difference between the tidal phenomena of the morning and evening of the same day, called the diurnal inequality, is often so considerable, and at some places so remarkable, that it is far less perfectly understood than any of the other inequalities, and furnishes, as we shall afterwards see, a source of far greater uncertainty in the determination of the establishment than any yet mentioned. It had not till of late been introduced, and still very sparingly, into tide-tables. To it, or rather to a want of the knowledge of it, are no doubt owing many of the uncertainties or ambiguities and errors which occur in recorded tide observations. It is of great importance both to the theory of the tides and to the purposes of navigation, that this diurnal inequality should be fully analysed. Mr Whewell's researches have opened a wide field, but here we can only notice them in a very general manner.

Were the earth wholly covered by water, the diurnal inequality of the heights of high and low water would depend on the semidiurnal transits of the poles of the equilibrium spheroid being alternately north and south of the equator. For example, if the moon had 20° north declination, the tide spheroid would have one pole in lat. 20° north, and the other in 20° south: and while the earth revolved, a place in lat. 50° north would have the tide which belongs to these two poles alternately; and being 30° from the one pole and 70° from the other, the two tides would be very unequal. On the same principles, in northern latitudes the tide which belongs to an upper transit of the moon should be the greater (of the two on the same day) when the moon's declination is north: when the moon crosses the equator, the difference of the two tides should vanish; when she has south declination, the tide which belongs to her upper transit should be the smaller. The contrary (as to greater and smaller) should be true of the tide which belongs to the inferior transit. The diurnal inequality may therefore be conceived to arise from a wave oscillating in the direction of the meridian, and of which the maximum height comes to each place once in twenty-four lunar hours; the minimum height arriving, of course, at the intermediate twelve hours. For such oscillations the Atlantic and Pacific both afford the most ample scope. If the time of the maximum height of this wave arriving at any port coincide every day with the time of high water, the alternate high water being at twelve hours interval, will be affected alternately with the greatest and least heights of the diurnal wave; and the intermediate low waters will coincide with the mean height of this wave, and will not be at all affected. In this case there will be a decided diurnal inequality in the height of the high water, but none in that of the low water. In like manner, if the time of the maximum height of the diurnal wave coincide with the time of low water, the height of low water will be marked with a diurnal inequality, while the height of high water will exhibit no such feature. But if the diurnal wave arrive every day at a time intermediate between high and low water, it will raise both the high and the low water which are nearest it, and will depress both the high and the low water which happen in the other half of the day. Hence both the high waters taken separately, and the low waters taken separately, will be marked by a diurnal inequality; and this inequality will be greater for high water or for low water, according as the time of the maximum of the diurnal wave is nearer to the time of high or low water.

There are various places at which it has long been known that there is commonly a difference in the morning and evening tide of the same day. It is stated by Colepress in 1668 (Phil. Trans. vol. iii. p. 633), that at Plymouth the tides, from about the end of March till the end of September, are about a foot higher in the afternoon than in the forenoon, and *vice versa* the rest of the year. But we shall soon see that this way of expressing the fact, by speaking of evening and morning tides, is quite inaccurate. The other inequalities of the tides having been found to follow the laws of the equilibrium theory (although the constant elements, the magnitudes and epochs, can be determined only by observation), and Mr Whewell having found the diurnal inequality very clearly marked in the Plymouth observations, he attempted to trace its laws by assuming a similar correspondence with the equilibrium theory. The result confirmed the assumption in a striking manner, the age or epoch of this inequality for Plymouth being about four days.

At Sincapore the diurnal inequality of low water is of a magnitude which could not have been anticipated, the height of the evening and morning tide often differing six feet; although the whole rise of the mean tide is only seven feet at spring tides, and the difference of mean spring and neap tides not more than two feet. The epoch at that place is about a day and a half. It is a curious circumstance, that the sun affects the low water at Plymouth more than the high water; and that the moon's declination at Sincapore affects the low water four times as much as the high water, while at Plymouth it affects it less.

It is easy to conceive the diurnal inequality carried a little farther than it is at Sincapore, so that at a certain stage of it the alternate tides would entirely vanish. This is equivalent to supposing the highest low water and the lowest high water to have the same height, of which examples will afterwards be given.

Captain Fitzroy having caused observations be made at King George's Sound, on the south coast of New Holland, every half hour for some days, and for a portion of the time every quarter of an hour, found that on March 7th and 8th 1836 there were two very unequal tides, and that on the 9th and 10th there was only one tide; but a recession and return in the high water, which had been barely perceptible on the 11th, became more and more marked on the 12th, 13th, and 14th, so as again to give two tides each day. Thus at this place it appears to be only at one particular period of the semilunation that we have a single-day tide. That of Tonquin was referred by Newton to the interference of two tides which arrive by different channels. The great diurnal inequality of Sincapore, which is in the same seas, appears to be clearly due to the effect of the moon's declination; and the determination of this point, and the circumstances ascertained to occur in the reputed single-day tide of King George's Sound, throw some doubt on the explanation just referred to; nor can this doubt be removed till the tides of those seas have been more fully observed.

That this inequality cannot properly be called an excess of the evening tide at one season of the year, and of the morning tide at another, must now be evident from the circumstance that the high water at Plymouth is on the average five hours after the moon's transit. Suppose the moon to move in the ecliptic, which is her average path when the sun's right ascension is five hours (that is, about

June 7), the tide which follows the moon's transit will follow the sun's transit also as soon as the moon is north of the equator; that is, if the diurnal inequality were regulated by the moon's place on the same day, the afternoon tide would be greatest, and so it would continue till the moon was seven hours after the sun, and the tide following the moon would become the morning tide: but at the same time the moon would pass to the south of the equator, and so the tide following the moon would be the smaller. In this situation, therefore, the evening tide would be the greater during the whole lunation.

It was only of late that the diurnal inequality of the tides began to be attended to as it deserves; for however imperfectly understood, it is no doubt a regular change, considerable in its amount, and almost universal in its prevalence. It would be easy to adduce many cases in which the safety or loss of a ship has been determined by it. Though the existence of such an inequality in particular places has long been known, its laws have been sadly misunderstood. For example, it has been supposed always to affect the morning and evening tides in opposite ways, which is only an accidental and local expression of its rule. In the Phil. Trans. for 1836, p. 57, Mr Lubbock has described how he obtained it for Liverpool; while Mr Bywater, who has introduced it into his tide-tables for that port, and Mr Bunt into those for Bristol, have also collected it from observations. But the connection of this inequality, as it exists in different parts of the world, was never brought into view till Mr Whewell discussed together the European and American observations of June 1835. The laws which the inequality follows, when thus considered on an extensive scale, appear to be very curious, though they are still but very imperfectly known.

In some cases this inequality is most clearly seen in the heights of high water, in others in the low water, and in some cases it greatly affects the times of both. Mr Whewell exhibited the results of June 1835 in curves, by erecting a series of equidistant ordinates to represent the heights of the successive tides above a fixed point at each place; and these curves generally showed a series of parallel zigzags (the tides being alternately higher and lower); and they were so regular and similar as to prove both the goodness of the observations and the existence of the diurnal inequality. This was so remarkable on the coast of America, that scarcely any exception occurred. Next to this, it was conspicuous, especially during a portion of the observations, in Spain and Portugal; then on the west of France, the coast of Cornwall, and parts of the west of Ireland. In the German Ocean this inequality was obvious, but, owing to the mixture of different tides, it was less steady and regular.

Although the diurnal inequality is generally believed to depend upon the sun or moon's being north or south of the equator, yet, as we shall afterwards see, there are cases which it seems very difficult to explain on this principle. Nor does the sign of this inequality, as was long supposed, depend on the place being north or south of the equator. Its maximum corresponds to, but is not necessarily simultaneous with, the moon's greatest declination; nor does the period of its vanishing everywhere coincide with the time of the moon's passing the equator, but more generally is somewhat later. Between periods corresponding to, or rather at equal intervals after, two such passages, the inequality increases from 0 to a maximum, and decreases to 0 again, alternately. The curves which represent the heights really exhibit such alternate increase and diminution; and the inquiry naturally occurs, after how long a time does the moon's position show its effect in the diurnal inequality? In the case of Liverpool, Mr Whewell has endeavoured to show that this inequality expresses the effect of the forces upon the equilibrium spheroid, as they existed six days previously. But this interval is very different at other places, and its range is curious.

From the general tide observations made in Europe and America in June 1835, the results of which have been given by Mr Whewell (Phil. Trans. for 1836, p. 302), it appeared that the diurnal inequality on the east coast of Scotland was, during that semilunation, irregular, passing over a tide in the middle of the series. This and others of its anomalies on the coasts of the German Ocean, appear to show that the waters in that region are affected by the mixture of different tides. On the east coast of America, the changes of this inequality seem contemporaneous with those of the moon's declination; so that the epoch there is zero. On the coasts of Spain, Portugal, and France, it is successively two and three days, which is quite consistent with this epoch, being four days on the coast of Cornwall and Devonshire.

A circumstance not less remarkable in the progress of the diurnal inequality is, that it is seen much more distinctly and steadily at some places, than at others which are near them; nor does it seem easy to assign any rule which it follows in this respect. It is very marked, and almost universal, on the coast of the United States, and was conspicuous in the observations of June 1835 in Spain and Portugal, the west of France, and part of the west of Ireland; yet at intermediate places it could not be detected. It is large on the east coast of New Holland, as we know from Cook's getting his ship off a reef by means of it; and the north and south coasts of Australia appear to exhibit the extreme case of it. We might suppose it to affect the whole of the Indian Ocean; yet at Keeling Island, in the middle of that ocean, it did not decidedly show itself in Captain Fitzroy's observations from the 2d to the 8th April 1836.

The epoch of the diurnal inequality being different in different parts of the world, is a very curious fact, and not easily reconcileable with the notion of a tide-wave travelling to all shores in succession. In accordance with this view, the tide on the shores of America had been considered as identical with the almost contemporaneous tide on the coasts of Spain and Portugal; nor does it seem easy to imagine the form of the tide-waves, so that this shall not be the case. Yet we find that the tides on these two sides of the Atlantic cannot be identical in all respects; for on the 9th, 10th, and 11th of June 1835, when the diurnal inequality was great in America, it was nothing in the west of Europe; and on the 18th and 19th, when this inequality had vanished in America, it was great in Europe. It would seem as if the tidal phenomena on this side the Atlantic corresponded to an epoch of the equilibrium theory, two or three days later than the same phenomena in America; and different kinds of phenomena do not seem to travel at the same rate. Thus the equilibrium theory, though it may explain the general form of the inequalities, cannot give their epochs and amounts by any possible adjustment of constants. The notion of the progress of the tide-wave from south to north in the Atlantic is still further involved in difficulties by its appearing, from the observations of Sir John Herschel, that at the Cape of Good Hope the diurnal inequality showed itself most clearly on the 17th, 18th, and 19th of June, that is, as late as in Spain and Portugal. The diurnal inequality appears also, but not so generally, in the curves which represent the times; nor is this difference always in the same direction. Thus on the coast of America, at some places, the afternoon tides were later than the mean, and those of the forenoon earlier than the mean, for a great part of June 1835, while at other places the reverse was the case.

From certain tide observations made in the Indian Seas, and examined by Mr Whewell, we select the following as striking features in those of Surat Roads in the Gulf of Cambay, Gogah on the opposite side of the same gulf, and Bassadore in the Island of Kismis at the entrance of the Persian Gulf. In the first two places there is an enormous diurnal inequality of the heights, amounting sometimes to seven or eight feet. It appears that this inequality vanishes and changes its sign about two days after the moon's declination does so. At Bassadore there is a very large diurnal inequality of the times, sometimes exceeding two hours, and sufficient to displace the tides. For instance, about the 23d November 1834, the tide-hour of the forenoon was greater by almost two hours than that of the afternoon, the former being at $5^{h.}\ 33^{m.}$ A. M. and the latter at $3^{h.}\ 41^{m.}$ P. M. What makes this anomaly still more remarkable is, that at this place there is little or no diurnal inequality of the heights, which is a most curious tidal feature, in addition to those already remarked in the Indian Seas.

From observations made at Petropaulofsk, in the Bay of Avatcha, latitude 53° 1′ N., long. 158° 44′ E. in 1827 and 1828, by the Russian Admiral Lütke, and transmitted to Mr Whewell, it appears that the high water there is affected in its time by a very large diurnal inequality, while the height is only slightly affected by an inequality of that kind. The height of the surface was carefully observed every ten minutes, day and night; and when near its maximum, every two minutes. This great care and labour, which would have been superfluous at most places, was quite necessary in this instance; for if the observations had not been thus continued, they would not have enabled Mr Whewell to detect the very curious laws of the phenomena about to be described. This diurnal inequality of the time reaches the enormous amount of above four hours. Thus the intervals between moon's transit and high water, on October 11 and 12, 1827, were as follows: $5^{h.}\ 38^{m.}$, $1^{h.}\ 39^{m.}$, $5^{h.}\ 20^{m.}$, $0^{h.}\ 56^{m.}$; on June 23 and 24, 1828, they were $7^{h.}\ 9^{m.}$, $3^{h.}\ 9^{m.}$, $7^{h.}\ 21^{m.}$, $2^{h.}\ 51^{m.}$; on October 15 and 16, 1828, they were $5^{h.}\ 13^{m.}$, $2^{h.}\ 0^{m.}$, $6^{h.}\ 7^{m.}$, $2^{h.}\ 46^{m.}$; showing an alternate increase and diminution to the extent above mentioned. The greatest alternate inequalities of the heights of high water during these series of observations, were something more than a foot. But the observations of low water are marked by additional features still more curious. For though in these the diurnal inequality of the times really appears, it is neither so large nor so regular as that of high water; it seldom exceeds an hour. The diurnal inequality of the height of low water, on the other hand, is much larger than that for high water, amounting to three or even four feet; and this in a tide of which the whole range rarely exceeds five feet. The diurnal inequality is supposed to depend principally upon the moon's declination; and its maximum and its disappearance have been found, at most places hitherto examined, to follow at a short interval (one or two days) the maximum and the vanishing of the moon's declination. On examining the Petropaulofsk observations with regard to this point, we find that the greatest and most regular of the diurnal inequalities above noticed (the inequality of the time of high water and of the height of low water) correspond with the moon's declination; so that the epoch or age is zero. On the contrary, not only is the epoch of the other two inequalities, that of the heights at high water and of the times of low water, different from that of the preceding, but they alternate with them, vanishing when the others reach their maxima, and showing their maxima when the others vanish. This is a very perplexing circumstance; for if the diurnal inequality depend upon the moon's declination, it is difficult to conceive how its effect upon the height of high water and the time of low water should be greatest just when the moon is in the equator, and that the reverse should hold in respect to the other two inequalities.

The tides of Petropaulofsk show more clearly than any yet examined, how the diurnal inequality may be so large as to lead to the appearance of only one tide in the twenty-four lunar hours. The heights of the high waters are alternately greater and less; as are also, in a still greater degree, the heights of the low waters. Thus some of the high waters are depressed, and some of the low waters elevated, till there is little vertical difference between the two. On the 17th of June, the rise from low to high water in the afternoon was only eight inches, although the rise in the forenoon had been four feet. In the same manner the fall from high to low water in the afternoon of June 22 was only two inches, and in the forenoon of June 23, only one inch, although the intermediate fall in the afternoon of those days was above four feet. From $6^{h.}$ to $8^{h.}$ on the 24th the surface remained stationary. Thus one of the two half-day tides being obliterated, we have only one tide in the twenty-four hours. It is to be recollected, however, that this takes place only at a particular period of each lunation, depending upon the declination of the moon. When, therefore, a traveller meets with such a phenomenon, if he would pursue his tide observations for a few days with assiduity, he would probably find the single-day tide resolve itself into the usual case of two daily tides.

The term *establishment* ceases to be applicable when the diurnal inequality affects the time of high water to so very large an amount as we have seen it does at Petropaulofsk; because at almost any time of the lunation the interval of moon's transit and high water may vary very much from one tide to another, and this uncertainty deprives the establishment of all utility in such cases, unless we also take into account the diurnal inequality.

If the usual diurnal inequality at any place be the effect of a tide-wave arriving at the shore once a day and superimposed upon the semidiurnal tide-wave, it is natural to ask whether such a mode of representation can be applied to the tides now under consideration. Mr Whewell, after attempting at considerable length to effect this, acknowledges that he is fairly outdone by the inequalities alternating in their vanishing and maxima, as above described.

The tides at the Isle of Sitkhoe, latitude 57° 2′ N. and longitude 135° 18′ W., exhibit a very great diurnal inequality both in the heights and times. The amount of this in the time of high water reaches an hour ($30^{m.}$ positive and $30^{m.}$ negative); at low water it is somewhat less. The diurnal inequality of the height of high water is two and a half feet, at low water its maximum amounted to five feet; the greatest rise from low to high water being about fifteen feet. In other respects this case is similar to that of Petropaulofsk, except that the tides never become single. The same communication of Admiral Lütke contained an account of the great diurnal inequalities of Port de la Coquille and of Port Lloyd, as also of the establishments of several other places in the North Pacific; but, as already stated, the term establishment becomes extremely vague, and almost unmeaning, when applied to seas in which the phenomena of the tides are such as above described.

From the account of Admiral Freycinet's voyage, it appears that at several places in the North Pacific, the tides, as observed in that expedition, exhibit features similar to those here noticed. It has often been lamented that so few tide observations have been made in distant parts of the world; but it is now sufficiently clear, that if, in places such as those now noticed, the observations are not made with great care, and continued for a length of time, they can only serve to mislead.

The Rev. John Williams, who, from observations continued during several years' residence in the islands of the Pacific Ocean, had it in his power to furnish more certain information than could be obtained by any transient visitor, however profound in knowledge or diligent in research, has given a very intelligent account of certain tides in those regions in his "Narrative of Missionary Enterprises in the South Sea Islands," p. 200. It is a fact well known to the missionaries, that the tides in Tahiti and the Society Islands are uniform throughout the year, both as to the time of the ebb and flow, and the height of the rise and fall; it being high water invariably at noon and midnight, and low water at six in the morning and evening. The total range from low to high water seldom exceeds eighteen inches or two feet. Generally once, and frequently twice in the year, a very heavy sea rolls over the reef, and bursts with great violence upon the shore. But the most remarkable feature in this periodically high sea is, that it invariably comes from west and south-west, which is just the opposite of the trade-wind. The eastern sides of the islands are never injured by these periodical inundations. Mr Williams is anxious to call the attention of scientific men to this remarkable phenomenon, which he believes to be restricted to the Tahitian and Society Island groups in the South Pacific, and the Sandwich Islands in the North. But he cannot speak positively respecting the islands eastward of Tahiti; but at all the islands he has visited in the same parallel of longitude to the southward, and in those in the same parallel of latitude westward, the same regularity is not observed, but the tides vary with the moon, both as to the time and magnitude of the tide, which is the case at Rarotonga. He is also anxious to correct the erroneous statements of some scientific visitors, particularly of Kotzebue, who asserts that "every noon the whole year round, at the moment the sun touches the meridian, the water is highest, and falls with the sinking sun till midnight!" According to Captain Beechy, "the tides in all harbours formed by coral reefs are very irregular and uncertain, and are almost wholly dependent upon the sea-breezes. At Oututaunoa, it is usually low water about six every morning, and high water half an hour after noon. To make this deviation from the ordinary course of nature intelligible, it will be better to consider the harbour as a basin, over the margin of which, after the breeze springs up, the sea beats with considerable violence, and throws a larger supply into it than the narrow channels can carry off in the same time, and consequently during that period the tide rises. As the wind abates, the water subsides; and the nights being generally calm, the water finds its lowest level by the morning."

"This statement," says Mr Williams, "is certainly most incorrect; for not only have I observed for years the undeviating regularity of the tides, but this is so well understood by the natives, that the hours of the day and night are distinguished by terms descriptive of its state: as, for example, instead of asking 'What is the time?' they say 'Where is the tide?' Nor can the tides, as Captain B. observes, be 'wholly dependent upon the sea breeze;' for there are many days during the year when it is perfectly calm, and yet the tide rises and falls with the same regularity as when the trade-winds blow; and we very frequently have higher tides in calms than during the prevalence of the trade-wind; besides which, the tides are equally regular on the westward or leeward side of the islands, which the trade-wind does not reach, as on the eastward, from which point it blows. But the perfect fallacy of Captain Beechy's theory will be still more apparent, if it be recollected that the trade-wind is most powerful from mid-day till about four or five o'clock, during which time the tide is actually ebbing so fast, that the water finds its lowest level by six o'clock in the evening; and that in opposition to the strength of the sea-breeze, Captain Beechy adds, 'that the night being calm, the water finds its lowest level by morning;' whereas the fact is, that the water finds its highest point at midnight when it is perfectly calm. How then can the tides be dependent on the sea-breeze?"

Mr Lubbock thinks some of these extraordinary anomalies may perhaps be accounted for by considering the continent of South America as a dam, preventing the derived tide-wave from flowing freely into the Pacific from the great Southern Ocean.

Owing to the tide-wave which enters the German Ocean by the north coast of Scotland, not reaching the mouth of the Firth of Forth at the same time with the other tide-wave which comes through the Straits of Dover, there are frequently four, and sometimes six tides a day, observed in the upper part of the Firth of Forth. These peculiarities are most conspicuous about the time of spring tides, and gradually decrease till the neaps, when they vanish altogether. For the particulars, we beg to refer to the Reports of the British Association on Waves, by Sir John Robison and Mr Russell. But so long ago as the year 1750, peculiarities had been observed in the tides of the Forth, as described by Wright in the Phil. Trans. for that year.

River-tides.

When a tide-wave arrives at the mouth of a river, it enters in a manner similar to that of a derivative tide into a narrow sea; and though there are generally some features peculiar to each river in the entrance of the tide-wave, it afterwards assumes a direction at right angles to the current, and advances regularly up the stream. If the channel gradually narrows upward like a funnel, the height of the tides will be increased by this convergence. Where the width is nearly uniform, the tide will gradually die away, and still more rapidly if the channel spreads out. In the Amazons the tide continues to ascend for several days against the stream, and is still sensible at 200 leagues from its mouth. Seven or eight tides, with intermediate low waters, follow in continual succession up this mighty river. Something similar takes place in the St Lawrence, the tides reaching 432 miles up the main channel to a point between Montreal and Quebec. Among other plausible reasons to account for the tide not ascending the Mississippi, its crookedness has been assigned as a very sufficient one. But the best of all reasons seems to be, that there is next to no tide in the sea at its mouth; the total rise there being only about eighteen inches. When the tide, on entering a river, is made to rise greatly by the contraction of the channel, the part of the water so affected may be abruptly terminated on the inland side, owing to the depth and quantity of the water on that side not admitting of the surface there being immediately raised by means of transmitted pressure. A tide-wave thus rendered abrupt has a close analogy with the waves which curl over, and break on a shelving shore, and is called a *bore*. In many places it occurs in such magnitude as to produce great noise by the violent intestine motion of the water. Though it appears to travel with great rapidity, it in fact moves more slowly than the tide-wave under any other circumstances. The bore which enters the Severn is nine feet high; that in the creek of Fundy is said to be still higher. In the Garonne this phenomenon takes place near Bordeaux, and is called there the *Mascaret;* at Cayenne it is called the *Barre*. It occurs on a grand scale in the river Amazons, at the junction with the Arawary, having there a face twelve or fifteen feet in height, and producing a noise which may be heard at two leagues distance. The Indians of the neighbourhood call it *Pororoca*. Ships are often exposed to considerable danger from the bore, especially in the more shallow parts of a river, and near the shore.

Height of the tide.

The range of the tide, that is, the height of high water above low water, is very different at different places, and is affected by circumstances which it is often very difficult to analyse. It is however clear that the configuration of the coast exercises a very considerable influence upon the amount of this range, according as it makes the tides converge or diverge. Thus the range is very much increased in deep in-bends of the shore, which are open in the direction of the tide-wave, and gradually contract like a funnel, such as the Bristol Channel, the Gulf of Avranches, the Bay of St Malo, and the Bay of Fundy, where sometimes it very considerably exceeds seventy feet, some say 100. On the con-rary, the tide is much diminished at promontories under ertain circumstances. Thus at the south-east point of Ireand (at Arklow, Glynn, and Cahore) the greatest range is iot more than three feet, while at a little distance along he coast each way it becomes twelve or thirteen feet; and his small amount of the tide on one side of the channel is he more remarkable, because it is just opposite the enornous range which occurs in the Bristol Channel, amountng at Chepstow to sixty feet. The smallness of the tide n the middle of wide oceans, as at the islands of the Pacific, vhere it amounts only to two or three feet, affords no proof hat this would be the amount on a globe entirely covered vith water; for the interruption produced by the continents ntirely modifies the direction, height, or other circumtances of the general tide. This interruption will dimiiish, and in some cases entirely obstruct, the original tide-vave; and when a derivative tide does enter the oceans in uestion, it is diffused over so wide a space that its height is reatly reduced; so that in the same manner as the tides are ugmented by convergence, they are diminished by diffuion.

Mr Lubbock and Mr Whewell seem to have adopted the nost promising mode of advancing our knowledge of the ides. This is to examine the laws which can be collected rom observations, taking so great a number of these that he effects of all accidental causes may disappear in the aveage results. The collection registered at the London docks, nd first discussed by Mr Dessiou under the direction of Ir Lubbock, afforded an admirable opportunity for such an xamination, since it included 13,073 observations, and a eriod of nineteen years, from January 1, 1808, to Decemer 31, 1826. But it is very unlikely that the discussion, owever systematical, of observations at any one place, hould exhibit clearly the true principles of the theory; and, esides, with respect to the phenomena of the tides at Lonon, they are in some measure masked by a curious comination of circumstances, namely, by the mouth of its river eing in a sort of inland sea, and at a part of an island turnd away from the side against which the tide-wave impinges, nd so situated, too, that the progress of the tide round the ne end of this island occupies about half a day more than hat round the other. These two tides, being thus of diferent ages, and meeting near the mouth of the Thames, ust affect the character of the tide at London. It will no oubt require the accumulation and discussion of many rge collections of observations at various places to put us the certain possession even of the empirical laws of the henomena; and whether or not this be the only practiable way of arriving at the true theory, it is at least that o which, founding our expectations on the past history of cience, we may look with most hope. When we consider he enormous accumulation of observed phenomena and mpirical laws which preceded the discovery of the true rinciples of the celestial motions, we may reasonably supose that we are only at the outset of what is requisite to btain the same success with regard to the tides. It is herefore to be wished that such additional observations ay be made and discussed as may most speedily lead to a omplete and scientific knowledge of the subject.

The object, in examining a large collection of observaions, being to ascertain the manner in which the positions nd distances of the heavenly bodies affect the time and eight of the tide, the mode of proceeding is to examine ow these two quantities depend upon the right ascension, eclination, and parallax of the sun and moon, and upon ther astronomical elements, should such be required. The nean time of high water will be found to be affected by nequalities depending on the elements just mentioned; and he law and amount of these inequalities for any particular lace may be collected from observations made there, withut any reference to theory, provided the observations be sufficiently numerous, and their circumstances sufficiently varied. For it was in this manner that the greater inequalities of the moon's motion, the variation, the evection, and annual equation, were detected by observation, long before the celestial motions were referred to their true causes. Indeed, in the history of science, the instances seem to be comparatively few in which the general laws of the phenomena have been pointed out by the theory, before they had been gathered, at least approximately, from observation. The laws thus empirically obtained, besides serving for predicting the tides, may be used either as tests of the existing theories, or as suggestions for the improvements of those portions of mathematical hydraulics on which the true theory may be expected to depend. This, besides, is the way in which we are most likely to discover how the theory must be applied.

Reduction of the observations.

The best mode of obtaining from a considerable series of tide observations, at the same place, the establishment and age of the tide, which are the principal elements necessary for constructing tide-tables of the time for any particular place, appears to be that which was employed by Mr Lubbock and Mr Whewell. The times of high water are arranged according to the half-hour of the moon's transit on the day of the tide. Thus, all those tides which took place when the moon passed the meridian between $0^{h.}$ and $0^{h.}\,30^{m.}$ apparent time, are put in one class; all those when the moon passed between $0^{h.}\,30^{m.}$ and $1^{h.}$ in another class, and so on. The mean of all the times of transit in each class is taken, and the mean of the lunitidal intervals, or those between the times of transit and high water. We have thus a series of times of transit, with the corresponding lunitidal intervals. The interpolation for other times is most easily performed by means of a curve drawn on paper, ruled into small squares. The times of transit being laid down as abscissæ, the lunitidal intervals are erected as ordinates, and a curve is drawn approximating, as far as a regular form will allow, to the points thus found. This curve gives the intervals for any times of transit, and a table may be constructed by means of it. A similar course is followed for the heights; but for this and various particulars, we beg to refer to the Philosophical Transactions.

It has hitherto been usual, in discussing tide observations for obtaining from them the laws of the phenomena, to proceed upon the supposition that a series of several successive years was requisite, in order that the accidental irregularities might be compensated in the *means* of the observations, and the effects of the lunar inequalities thus come clearly into view. But in the Phil. Trans. for 1838, p. 231, Mr Whewell has shown that the laws of the phenomena, and the effects of the inequalities, may be deduced with considerable exactness from shorter series of observations; for example, from those of one year. He conceives that such an investigation will be of value in several ways. If the principal elements of tide-tables for each particular place can be obtained with moderate accuracy from short series properly discussed, the formation of such independent tide-tables for different places and times will become far less laborious, and may therefore be expected to be far more commonly practised. This will be a great advantage, not only because the tide-tables will thus become better, but also because several important questions may thus be settled; for instance, whether and how far the laws of tide phenomena change from place to place, and from time to time. But it is besides desirable to compare the results of short series with those of long ones, in order to appreciate the *practical* accuracy of our tide-tables. If, for instance, the mean of nineteen years gave a very exact rule for the effect of lunar parallax, while each single year deviated widely from this rule, it would be clear that the individual observations must be commonly affected by casual irregularities considerably greater than the parallax

Tides.

correction; and therefore the practical accuracy of the tables would be very little improved by introducing into them the parallax correction. But Mr Whewell has shown that the general law and the approximate amount of the parallax correction may be traced in the observations of a single year; and that thus the tables are rendered practically as well as theoretically better by such a correction being employed. The same is true, though less conspicuously, of the correction for lunar declination.

Tide-table.

Although the establishment and mean range of tide were known or given for every several port, yet no general tables have yet been framed, which, even with the help of those data, would equally apply to the computation of the several times and heights of their tides. So extremely imperfect is the present state of the general theory, that each place still requires to have its own particular tables for this purpose. Mr Lubbock has constructed auxiliary tables from which both the times and heights may be computed for Plymouth, Portsmouth, Sheerness, London, Pembroke, Bristol, Liverpool, and Leith, and the times for Brest and Howth. The hydrographer royal, Captain Beaufort, has actually computed and published the tide-tables to that extent for all those places, with the addition of the time for Ramsgate. Mr Lubbock's tables are also used for computing the tide-tables of the British and the Nautical Almanacs. With regard to the accuracy of the tide predictions so computed, Mr Lubbock says they will sometimes, though rarely, deviate an hour from the observed time of high water, owing to accidental causes. Generally, however, they may be depended on to within ten minutes; and it should be recollected that it is difficult to ascertain within five minutes the instant of high water, the fluctuations of height being then so very minute that the water is said to hang. The predicted amount of the height is liable to still greater uncertainties; which is the more to be regretted, because disastrous effects often arise from unexpected and unusually high tides, which are occasioned by storms and reduced atmospheric pressure.

Tolerably accurate tide-tables have long been published annually for London, and still better for Liverpool. But it has been the practice in this country to form tide-tables for other places, merely by taking the time which is stated in the London or Liverpool tables, and, if necessary, to add or subtract some constant quantity, according to the place. Even without this alteration the Liverpool tables have been generally used for the whole of the west coast of England. But tables are published, professing to give the hours at most of the principal ports of England in parallel columns, the times for different places having constant differences. Thus the hour of high water at Plymouth is stated as always 1$^{h.}$ 55$^{m.}$ later than the hour in the same half day at London, although they belong to different transits. The like may be said of the American Almanac, which in a similar manner professes to predict the tides for a great many places. Nor does the British Almanac or Edinburgh Almanac follow a more correct course. Indeed the tides in the latter have as yet been computed from the obsolete rules of Laplace. The assumption of a constant difference in the tide-hours at different places is by no means correct, as we might expect it to be from considering how the tide is transmitted from place to place, and as it appears to be from observation.

According to Mr Lubbock, the great obstacle to perfection in calculations or predictions of the tides, consists in the fluctuations of the establishments. Suppose the establishment to change a minute per annum, and that, having determined it from all the observations of twenty-one years, we employ it in calculations of the time of high water for the eleventh year, and compare the calculated times with the observed, they will not be affected with any constant error; but if we calculate for the twenty-first year, the calculated times will have a constant error of ten minutes. Similar remarks apply to the height. If the channel become deeper, the tide-wave travels with greater velocity, and the high water happens sooner. From a very ancient tide-table discovered by Mr Yates, and copied by Mr Lubbock into the Phil. Trans. for 1837, p. 103, it would appear that the tide at London had formerly been fully an hour later than at present. The argument or entry of the table is the day of the moon's age, which runs up to thirty days. The tide-hour on the first day is 3$^{h.}$ 48$^{m.}$; and with a daily increase of forty-eight minutes, it occurs just at 3$^{h.}$ on the thirtieth day.[1] But Mr Lubbock finds that the establishment of the port of London has been subject to changes even within the present century; and he notices the difficulty of predicting the time of high water with certainty, unless these changes can be accounted for. The high water appears now to be nearly as late as in 1804; in 1821 it was fully ten minutes earlier. The removal of the Old London Bridge appears to have affected neither the time nor the height of high water; but it has made the low water sink about eighteen inches more than formerly. The following table shows the establishment of the port of London, and mean height of tide when the moon's transit occurs at 0$^{h.}$; in other words, the mean time and height of tide at new and full moon from 1802 to 1835; supposing the moon's horizontal parallax 57′, and declination 15°.

Year.	Establishment.		Height.	Year.	Establishment.		Height.
	h.	m.	Feet.		h.	m.	Feet.
1802	2	5·9	21·90	1819	1	57·1	22·20
1803	2	6·1	22·14	1820	1	56·7	22·38
1804	2	7·4	22·42	1821	1	56·5	22·51
1805	2	4·5	22·17	1822	1	57·8	22·35
1806	2	6·3	22·11	1823	2	1·1	22·48
1807	2	0·9	22·15	1824	1	57·9	22·51
1808	2	4·7	22·07	1825	2	1·0	22·43
1809	2	4·4	22·39	1826	2	2·9	22·40
1810	2	4·2	22·21	1827	1	59·9	22·38
1811	2	0·8	22·43	1828	1	59·9	22·66
1812	2	0·0	22·48	1829	1	59·9	22·60
1813	1	58·7	22·30	1830	1	56·7	22·56
1814	1	59·8	22·33	1831	1	59·6	22·53
1815	1	59·8	22·19	1832	2	2·5	21·95
1816	1	58·5	22·34	1833	2	5·3	22·26
1817	1	57·2	22·31	1834	2	4·2	22·28
1818	1	57·0	22·40	1835	2	4·4	22·29

In 1832 none of the lower portions of the Old London Bridge, which obstructed the natural flow of the tidal waters, was removed excepting two piers; and in the following year almost the whole of that structure was cleared away as regarded the masonry and starlings, although the course of the river was far from being completely cleared, many portions still remaining a foot or two above low-water mark, and which were finally removed in 1834.

Hitherto no care has been taken to specify to which transit of the moon the tide at any place is referred, and various mistakes have originated in this want of precision. It seems desirable that some conventional agreement were adopted upon this point. Mr Lubbock has employed the transit which precedes a given high water at London by about two days three hours, and which, according to the notation already described, he terms transit B. If transit A, which occurs about twelve hours and twenty-five minutes sooner, e preferred, he does not object. This latter transit coresponds in syzygy to the average interval. At this period f the moon's age, the lunitidal interval changes rapidly, vhereas the height of high water is stationary; so that it s impossible to determine directly and with accuracy, how ong, after a given transit, the highest tide takes place.

---

[1] On this however we have to remark, that since the mean lunation consists of little more than twenty-nine days and a half, almost half the number of new moons would occur on the thirtieth day; so that, although the table had been in every other respect correct, it would not make the mean time of "flod at london brigge" on the day of new moon to have exceeded 3$^{h.}$ 26$^{m.}$. Flamsteed, in 1683, made it just 3$^{h.}$. His tables were the first which gave the time of the tide for the moon's lower transit, or twice a day.

From Mr Lubbock's examination of the progress of the de-wave, the vulgar establishments of the following places re, at

	h.	m.	
3rest	3	48,	reckoned from transit D
'lymouth dockyard	5	33,	D
sle Brehat	5	52,	D
'embroke dockyard	6	4,	D
3ristol, Cumberland Gates,	7	15,	D
Iowth harbour	11	8,	D
iverpool dock	11	25,	D
'ortsmouth dockyard	11	40,	D
eith	2	0,	E
ondon docks	1	57,	F

From this it is evident that the establishments of ports as iven in various works, often very inaccurately, are besides eferred to different transits of the moon without distincon, thereby creating great confusion.

Hence also it is found that the tide arrives at

	Days.	h.	m.	
3rest	1	4	27	after transit B, when the moon is in syzygy.
'ortsmouth	1	12	21	
iverpool	1	12	2	
eith	1	15	15	
ondon Docks	2	3	16	

o that the tide takes twenty-three hours forty-nine miutes in travelling from Brest round the north coast of cotland to the London docks. We are deficient of inormation with respect to the course of the tide-wave in the 'acific Ocean; and even on our own coasts the number of laces of which the establishment is accurately known is robably very small. The tide takes about twelve hours 1 proceeding from the Cape of Good Hope to Cape Blanco; hence it reaches Brest in about four hours. The crest of he tide-wave thus travels over the open ocean with imnense rapidity, and gives rise to a slow current, with which, owever, it must not be confounded.

At the instance of Mr Whewell, the British Association, vith the view of ascertaining what surface ought to be taken s the permanent level of the sea, caused a level line to be arried with great accuracy from the north shore of Someretshire to the south shore of Devonshire; and the position f this line has been fixed, so as to be recognised at any iture time, by means of marks at Axmouth, at East Quanockshead, at Stolford, and at Portishead. This line has lso been referred to the sea at its extremities; and the obervations show that the mean between the heights of high nd low water coincides, at least very nearly, at different laces, as well as at the same place at different times. Vhile the difference of the levels of low water at Axmouth n the English Channel, and Wick Rocks on the Bristol Channel, is not less than twelve feet, the mean water at hose two places coincides in level within a few inches. Against these conclusions, Mr Thomas has, in the Philosohical Magazine for August 1840, alleged various facts, which ve have no means of testing or deciding upon. To one part owever there seems a more serious objection than any that e has stated; for though we should think the mean water ery likely to be nearly constant everywhere, it cannot be ll on the same level if there be perpetual high water at ome places, as Mr Whewell himself alleges.

From six years' observations made at Plymouth, it apears that the height of mean water is constant from year o year within two or three inches. It appears also that he mean water for each fortnight has a semimenstrual inequality amounting to six or seven inches, the height of the mean water being greatest when the moon's transit is at 6h. and least when it is at 12h. The immediate cause of this is, that the semimenstrual inequality of low water is greater than that of high water at Plymouth. The result of one year's observations made at Dundee is, that the half-tide level is constant within 1·5 inch, except at eleven and twelve o'clock, when it deviates two inches on a tide of fourteen feet. At any rate, Mr Whewell's scheme of taking the half-tide level as a standard must be an immense improvement on the old system, in which the heights of buildings and mountains are referred to the level of the sea, or to high or low water mark. The heights of spring or neap tides, although not subject to so much uncertainty, are also quantities too vague to be used with propriety as standards of reference.

Influence of atmospheric pressure on the level of the sea.

It had been long observed by the people about Stockholm, that when the water in the harbour, which is an inlet of the Baltic Sea, subsides so as to allow the waters of the Mälar Lake, which has almost the mean level of the sea, to have free exit, the air is clear and dry; but when the reverse occurs, or the sea flows into the Mälar, wind and rain are likely soon to follow. This phenomenon was investigated by N. G. Schulten, who, after he had ascertained the truth of the popular belief, and compared it with the corresponding state of the barometer, explained it at considerable length in the Transactions of the Royal Academy of Stockholm for 1806, by referring it to opposite changes taking place simultaneously in the atmospheric pressure at Stockholm and in that at some considerable distance. The increment of pressure at the one place tending to depress the water there, just when the decrement of pressure at the other allows the water to rise, and the total pressure over the whole ocean being supposed constant, a tendency to equilibrium will result. Schulten's explanation, of which we suppose this to be the substance, is embarrassed with some irrelevant considerations; but there can be no doubt that it at the same time involves the true principle. His ideas, although well known at Stockholm, have not in other countries met with the attention they deserve. Some years ago they received a confirmation from M. Daussy, who, without being aware of Schulten's researches, has, from his own observations made at Brest, deduced the effects due to the changes of atmospheric pressure. Some account of these, accompanied by barometric tables, has been published (*Connaissance des Tems* for 1834, and *Annales de Chimie*, tome lxii.), and clearly exhibits the connection between the phenomena in question.

Mr Lubbock verified the same fact both at Liverpool and at London. At Liverpool he found the water rise eleven times as much as the barometer falls; and therefore the range of the barometer being three inches, the correction due to change in the atmospheric pressure may there amount to thirty-three inches. At London the water rises seven times as much as the mercury falls, and hence the range of the correction there is about twenty-one inches. On the coasts of Cornwall and Devon, Mr Walker found, that in ordinary cases a change of one inch in the barometer corresponds to sixteen on the height of the sea; but that in very sudden changes of pressure, one inch of mercury corresponds to twenty of sea-water. This last has been accounted for by considering that a sudden impulse given to the water would cause a rise or fall in the manner of a wave, beyond that strictly due to mere change of pressure. But this would at best hold good near the time of such change; and Mr Lubbock has remarked that it is sometimes very difficult to distinguish between the effects of pressure and those of the wind. Both wind and pressure may require to be attended to, especially where tide observations are continued during only a limited period. From the facts above stated, it would rather seem that the more confined the situation, the less is the effect of change of pressure; though this may, after all, be no general rule. But since the effects of variations of pressure do not accurately follow the inverse ratio of the specific gravities of water and of mercury, it is doubtful if the tides and these effects be independent of each other.

Influence of the wind.

The effects of wind on the level of the sea do not seem to have been much attended to; but Mr Lubbock has collected some important facts regarding its influence on the Thames. During strong north-westerly gales, the tide in the port of London marks high water earlier than otherwise, and does not give so much water, while the ebb tide runs out later, and marks lower; but upon the gales abating and the weather moderating, the tides put in and rise much higher, while they also run longer before high water is marked, and with more velocity of current, nor do they run out so long or so low. The reason assigned for all this is, that the strong north-west winds drive the sea along the Dutch coast, through the Straits of Dover, and consequently away from the mouth of the Thames; so that the tides during north-west winds are always much higher (producing frequently ruinous flooding) on the Dutch than upon the English coast. A south-westerly gale generally has a contrary effect, and an easterly one gives some water; but the tides in all these cases always improve the moment the weather moderates. This is the opinion of those most competent to form one from their daily experience, and is no doubt correct. The subject is one of considerable importance as regards the accuracy of which tide predictions are susceptible, and merits further inquiry, in order to ascertain if possible the error which may be expected for a wind of a given force and direction.

The progress of the tide-wave in most places must obviously be liable to be disturbed by great storms. Thus, during a violent hurricane, January 8, 1839, there was no tide at Gainsborough, twenty-five miles up the Trent, a circumstance unknown before. At Saltmarsh, only five miles up the Ouse from the Humber, the tide went on ebbing, and never flowed, till the river was dry in some places; while at Ostend, towards which the wind was blowing, contrary effects were observed. It has been supposed, that, owing to the sheltered situation of the port of London, the great undulations produced by the winds will be less sensible there than on the coasts of France, as, for example, at Brest. But it should be recollected, that if the tide at London come from the Atlantic, the irregularities felt at Brest will equally tend to affect it at all those places which it subsequently reaches.

Tide-gauge.

In the Phil. Trans. for 1838, p. 249, there is a particular description of a very complete machine, by Mr Bunt, for registering, in a continuous form, the rises and falls of the tides, or their height for any instant of time. The principal parts are, an eight-day clock, which turns a vertical cylinder revolving once in twenty-four hours; a wheel, to which an alternate motion is communicated by a float rising and falling with the tide, in an almost close chamber, and connected by a wire with the wheel, which is kept constantly strained by a counterpoise; and a small drum, on the same axis with the wheel, which by a suspending wire communicates one eighteenth of the vertical motion of the float to a bar carrying a pencil, which marks a curve on the cylinder, or on a sheet of paper wrapped round it. The leading principle is obviously the same with that which Mr Keith first applied to the register thermometers and barometers. Various tide-gauges on similar principles have been constructed by others, particularly by Captain Lloyd, Mr Mitchell, and Mr Palmer, and are described in previous volumes of the Philosophical Transactions.

Fitzroy's theory of the tides.

Hitherto the phenomena of the tides have to a certain extent been referred to the equilibrium theory, the actual elevation of the waters being compared with the elevation which the moon would produce if the earth and moon were both at rest. But on account of the interruption of the land, the general motion of the waters of the ocean cannot conform to this theory, or admit of a fluid elevation resembling that of the equilibrium spheroid following the moon from east to west, except in some parts of the southern hemisphere. The Pacific, the largest ocean of all, has very small tides in its central parts; and at its eastern shore, near Cape Horn, the tide-wave runs from west to east, although there is apparently nothing to prevent its following the usual course. From such considerations, viewed in connection with various tide observations on the eastern and western sides of the Pacific and of the Atlantic, Captain Fitzroy (Voyage of the Adventure and Beagle, vol. ii. appendix, p. 279) has been led to propose a considerably different theory, in which the tide of each large ocean is considered to be nearly as independent of the tides of other waters as if it were a lake. The central area of each ocean is further supposed to be occupied by a lunar wave oscillating so as to keep time with the moon's transits, and having its motion kept up by the attraction of that luminary acting at each return. From the skirts of this oscillating central area, tides are supposed to be carried on all sides by free waves, the velocity of which would depend upon the depth and local circumstances of the sea; and thus the littoral tides may travel in any direction, while the oceanic tides near the centre of the oscillating area may be small, or may altogether vanish. Such we take to be the substance of this theory, as explained, with some improvements, to the Cambridge Philosophical Society, by Mr Whewell. Single observations, as that gentleman has remarked, can be of little use in deciding upon such a theory. More light would be thrown upon it if the real forms and positions of the cotidal lines could be ascertained for the shores of the Pacific. With this view it is desirable that numerous and connected observations were made on the eastern shores of Australia, the Indian Archipelago, the Philippine Isles, the Loo Choo Isles, and those of Japan. But we suspect that the magnitude and peculiarities of the diurnal inequality in some of those regions would throw great difficulties in the way of determining the cotidal lines, if they even admit of them at all.

Some of the facts which Captain Fitzroy considers most difficult to be reconciled with the theory which deduces tides in the Northern Atlantic from the movement of a tide-wave originating in the Southern Ocean are, 1st, the comparative narrowness of the space between Africa and America, with the certainty, that the sea is neither uniformly nor excessively deep in that space, and the trifling rise of the tide, not only upon each nearest shore (where it does not exceed four or five feet), but at Ascension Island, where the highest rise is not quite two feet; 2dly, the absence of any regular tide about the wide estuary of the river Plata, the situation and shape of which seem so well disposed for receiving an immense tide; 3dly, the flood-tide moving towards the west and south along the coast of Brazil, from near Pernambuco, to the vicinity of the river Plata; and, lastly, the almost uniformity of the time of high water along that extent of the coast of Africa which reaches from near the Cape of Good Hope to the neighbourhood of the Congo.

Against the supposition that a tide-wave travels southward along the west coast of America, are the facts, that the flood-tide impinges upon Chilóe and the adjacent outer coast from the southward of west; that it is high water within half an hour of the same time at Cape Pillar and at Chilóe, including the intermediate coast; that from Valdivia to the Bay of Mexillones (differing 18° in latitude), there is not an hour's difference in the time of high water; that from Arica to Payta, and from Panama to California, the times change gradually as the coast trends westward; and at from forty to sixty north latitude, high water takes place one time.

In about 55° south latitude is the only zone of ocean hich could follow any thing like the law that would go-ern its undulations if the globe were wholly covered with ater. In other zones (taking about ten degrees in lati-de as the breadth of a zone), it is high water, generally eaking, at one side of an ocean near the time it is low n the other. In oceans about 90° wide, this happens very arly; but as the width diminishes, so do the times of high ater at each side approach; and as the width increases yond 90°, as in the case of zones of the Pacific, the times high water still approach, in consequence of the tendency high water simultaneously at opposite sides of the globe.

Along the east side of the Atlantic, from the Canary Isles Scotland, it is high water within an hour of four o'clock the salient points of the coast; and if the opposite ast were straight, like that of Chili, and uninfluenced by rivative tides or by currents, we might expect that it ould be high water there at about $7^{h.}$, allowing that the e-wave moved as it is found to do generally. But it is gh water at about $1^{h.}$ from 30° to 40°, the times increas-ig northward from 40° N. to the Bay of Fundy, and also creasing southward from 50° N. to that bay, where the es probably rise higher than in any other part of the rld. This sequence of times, each ending in about 43° , the adjacent gulf-stream, and the excessive accumula-n of water, show that we cannot there expect to find ta for tidal rules. In that quarter it is evidently a mark- exception, caused by the conflux of at least two primary es, two derivatives, and a powerful current, aided by the culiar configuration of the land. On the west coasts of land and Scotland, the hour of high water is from $5^{h.}$ to ; on the coast of Labrador, it is from $10^{h.}$ to $11^{h.}$ in the ne parallels. The meridian distances are from three to r hours; but as we approach the parallel of 60° N., the rthern Ocean and Davis Straits open, which probably af-t the tide between Ireland and Labrador.

The Indian Ocean appears to have high water on all es at once, though not in the central parts at the same e. Thus, it is high water at the north-west extremity Australia, on the coast of Java, on that of Sumatra, at ylon, at the Laccadiva Islands, at the Seychelles, on coast of Madagascar, and at Amsterdam Island, at $^{h.}$; but at the Chagos Islands and Mauritius it is high water at about $9^{h.}$, and at the Keeling Isles about $11^{h.}$. It is to be observed, that the various tide-hours above mentioned are meant to be in Greenwich time.

High water taking place within an hour of the same time all along the east coast of Africa, shows that the rise of the sea or tide-wave there moves westward or eastward, and the times of high water at the islands are further confirmations; for the wave is at Chagos and at the Mauritius three or four hours before it is high water on the African coast. The Keeling time shows that there the water rises longer, in consequence of that part of the ocean being affected by the advancing swell of the Pacific.

Such is the substance of a few of the ingenious statements which Captain Fitzroy has advanced in favour of his theory; for we have not room for one fourth of them, and they do not readily admit of abridgement. He seems however to proceed upon the supposition that the moon could keep detached oceans of any dimensions in a state of perpetual oscillation; whereas it is easy to conceive oceans of exceedingly different dimensions, and yet not so much as one of which the moon could make oscillate to an extent deserving the name of a tide, or in fact produce in it any motion which would both continue till, and have the proper direction at, the next transit; because the times of oscillation, which naturally belonged to these oceans, might neither be equal to the intervals between the lunar transits, nor yet have any other ratio or relation to them which would tend to continue the movement. Some of Captain Fitzroy's reasoning, it is true, seems to imply that without any previous oscillation in the water, a single transit of the moon could produce a sufficient tide; and should it be able to effect this, which is very improbable, the above objection would rather be applicable to that theory as explained by Mr Whewell. The circumstance however of the tide-hour varying but little along a great extent of coast, instead of arguing much in favour of the new scheme, is quite in conformity with the principles upon which Mr Whewell has laid down his cotidal lines. But whatever may be the merits of Captain Fitzroy's theory, we have some doubts if it has much novelty to recommend it; something very similar having been proposed, and rather more systematically, by Dr Young, considerably above thirty years ago (Natural Philosophy, vol. ii. p. 343); and he has also comprehended it in an improved form in the theoretical part of the present article, more particularly in the fourth section. (E. E. E.)

TIDESWELL, a market-town of the hundred of High ak, in the county of Derby, 160 miles from London. It i in a lofty situation, and takes its name from a well near i which, like the sea, ebbs and flows at intervals, rapidly i wet, but slowly in dry seasons. It is an ill-built place, th a large old church, and has a market on Wednesday. he inhabitants amounted in 1821 to 1543, and in 1831 to 53.

TIDORE, one of the Molucca Isles, in the Eastern Seas, out twenty-one miles in circumference, situated on the st coast of Gilolo, three leagues south of Ternate, from ich it is separated by a safe channel, with good anchorage ar the town. It is mountainous towards the centre; the untains are high, and generally covered with clouds; and lower country is well watered by streams which flow m the elevated ground. It is populous, and formerly ntained twenty-five mosques. The Mahommedan faith nerally prevails. The island was first visited by the Spa-rds under Magellan. Here they formed a settlement in 21, and in 1527 they were driven out by the Portuguese. 1607 the Dutch arrived in those seas, and soon after ex-led the Portuguese; from which time till its capture by English, it remained in their hands. The sultan was at one period a very considerable potentate, but was entirely under the power of the Dutch, who elevated or deposed sultans according to their pleasure. The island carries on a considerable trade with New Guinea, Gilolo, the northern islands, and the Chinese. In 1579 Drake arrived at Tidore. Long. 127. 25. E. Lat. 0. 45. N.

TIGA, a small island in the Eastern Seas, near the north-west coast of the island of Borneo. Long. 112. 14. E. Lat. 6. 25. N.

TIGRIS. This large and celebrated river, which flows along the boundaries of the Turkish and Persian empires, has its rise in the mountains of Armenia, about fifty miles to the north-west of the valley of Diarbekir, and fifteen to the east of the source of the Euphrates. It derives its ancient Persian name of Tir or Teer, the arrow, from the swiftness of its stream, its average rate being about seven knots an hour. Not being within the range of the periodical rains, its waters begin to rise in April, with the melting of the winter snows in the mountains; its second rise takes place in the beginning of November, with the setting in of the winter rains. The spring inundation is however the greatest, and it is then only that a complete inundation covers the land, and that by the conflux of the waters of the Tigris and the Euphrates. Bagdad stands like an island in the midst of a wide ocean. To the annual overflowing of these two streams the country is indebted for its fertility. The Tigris is not navigable above sixty miles beyond Bagdad for vessels of more than twenty tons burden; though the intercourse is still maintained much higher up, by a kind of float called a kelek, which was used in ancient times, and which carries both passengers and merchandise, chiefly corn and copper, from Mosoul to Bagdad. It is singularly well adapted for its purpose, consisting of a raft in the form of a parallelogram. The trunks of two large trees crossing each other are the foundations of its platform, which is composed of branches of osier twigs ingeniously fastened to the stems below. To this light bottom are attached sheep-skins filled with air, and on these the floor is laid. These vessels are floated down to Bagdad with the current, where, after their cargoes are disposed of, they are taken to pieces and sold, it being impossible to return with them against the stream. Between Bagdad and Korna the Tigris is about 200 yards wide. At the latter place it joins the Euphrates; and the united stream, under the new name of Shat-el-Arab, falls into the Persian Gulf. This river was particularly famed in antiquity; and many of the greatest cities, as Nineveh, Seleucia, and Ctesiphon, were built upon its banks. The Tigris and the Euphrates, though they rise within fifteen miles of each other, soon separate, and running parallel, but at a greater distance, enclose the extensive province of Algesira. At Bagdad they again approach within thirty miles, and afterwards separate, forming the rich district of Irak Arabi. (F.)

TIGUIL, a river of Kamtschatka which falls into the Penjinskaia gulf. On its banks is the fort of Tiguilskoi, the strongest in the country, where a Russian garrison is maintained, to keep in awe the wild tribes of the country.

TILBURG, a city of the Netherlands, in the province of North Brabant. It has been only of late years raised from the class of towns to that of cities. It stands on the river Lay, in a healthy district, chiefly flourishing by the extension of its manufactures, which provide fine broad cloths, casimeres, common cloths, beavers, and military cloth. In 1833 it contained 11,726 inhabitants, most of of them adhering to the Romish church.

TILBURY, a village of the hundred of Barnstaple, in the county of Essex. It is only remarkable for the strong fortifications constructed there to command the course of the river Thames. It contains a regular work, which can be surrounded by water, and has more than 100 cannon, from twenty-four to forty-eight pounders, directed towards the stream. It is nearly opposite to Gravesend in Kent, on a bend of the river. Near it are the vestiges of the camp formed by Queen Elizabeth at the time of the expected invasion by the Spanish Armada. The population in 1821 amounted to 249, and in 1831 to 276.

TILLOTSON, JOHN, archbishop of Canterbury, was the son of Robert Tillotson of Sowerby, in the parish of Halifax in Yorkshire, clothier; and was born there in the year 1630. He studied at Clare Hall, Cambridge, and in 1651 became a fellow. In 1656 he left the university, in order to become tutor to the son of Edmund Prideaux, Esq. of Ford Abbey in Devonshire. He was afterwards curate to Dr Hacket, vicar of Cheshunt, in Hertfordshire. In 1663 he was presented by Sir Thomas Barnardiston to the rectory of Ketton or Keddington, in the county of Suffolk; but was the next year chosen preacher to Lincoln's Inn, when he procured Ketton to be bestowed on his curate. He was greatly admired in London for his sermons; and in the same year was chosen Tuesday-lecturer at St Lawrence's church, where his lectures were frequented by all the divines of the city, and by many persons of quality and distinction. In 1666, he took the degree of D. D. at Cambridge; in 1669, was made prebendary of Canterbury; in 1672, was admitted dean of that cathedral; and three years afterwards, was made a prebendary of St Paul's cathedral. In 1679, he became acquainted with Charles earl of Shrewsbury, whom he converted from popery; and the next year he refused to sign the clergy of London's address of thanks to King Charles II. for not agreeing to the bill for excluding the duke of York. In 1683, he visited the unfortunate Lord Russell when under condemnation, and attended him in his last moments on the scaffold. In 1689, he was installed dean of St Paul's; made clerk of the closet to King William and Queen Mary; and appointed one of the commissioners to prepare matters to be laid before the convocation, in order to a comprehension of all Protestants, as well dissenters as churchmen; but this attempt was frustrated by the bigotry of those members of that body who refused to admit of any alteration in things confessedly indifferent. In 1691, Dr Tillotson, notwithstanding the warmest remonstrances and entreaties on his part, was consecrated archbishop of Canterbury, and four days after was sworn one of the privy council; their majesties always reposing an entire confidence in his prudence, moderation, and integrity. In 1694, he was seized with a palsy, of which he died in the 65th year of his age. He was interred in the church of St Lawrence Jewry, where a handsome monument is erected to his memory. This learned and pious divine, while living, was greatly inveighed against by the enemies of the revolution. After his death there was found a bundle of bitter libels which had been published against him, on which he had written with his own hand, "I forgive the authors of these books, and pray God that he may also forgive them." It is remarkable, that while this truly great man was in a private station, he always laid aside two tenths of his income for charitable uses. One volume in folio of Dr Tillotson's sermons was published in his lifetime, and corrected by his own hand. They were translated into French by Barbeyrac. Those which were published after his death by his chaplain Dr Barker, form two volumes in folio, the copy of which was sold for L.2500. This was the only legacy he left to his family, his extensive charity having consumed his yearly revenues as constantly as they came to his hands. King William however gave two grants to his widow; the first of which was an annuity of L.400 during the term of her natural life, and the second of L.200 as an addition to the former annuity. Tillotson wrote some other works besides his Sermons; and also published Dr Barrow's Works, and Bishop Wilkins's Principles and Duties of Natural Religion, as well as a volume of that prelate's Sermons.[1]

TILLOUTA, a town of Hindustan, province of Bahar, and district of Rotas, pleasantly situated on the north-west bank of the river Soane. Long. 84. 15. E. Lat. 21. 48. N.

TILSIT, a city of East Prussia, in the government of Gumbinnen, the capital of a circle of its name. It stands on the river Memel, where the Tilse falls into that stream. It contains three churches, a hospital, 860 houses, and 12,800 inhabitants, who conduct manufactories of linen goods, hosiery, and gloves, and have many distilleries and breweries. The trade is considerable. At this place the emperors of Russia and France met on a raft in the middle of the river, and concluded, in 1807, the peace which bears the name of this town. Long. 21. 49. E. Lat. 55. 4. 30. N.

TIMAAN, or TIMOAN, a small island, high and woody, situated off the east coast of the Malay peninsula. There are several other smaller islands lying to the westward. Long. 104. 5. E. Lat. 2. 52. N.

TIMAHET, a town of Hindustan, in the nizam's territories, in the province of Beeder, fifty-four miles south-west from Hyderabad. Long. 78. 27. E. Lat. 16. 30. N.

---

[1] Birch's Life of Dr John Tillotson, Lord Archbishop of Canterbury. Lond. 1752, 8vo.

TIMBER.

THE term " timber" is applied to wood of sufficient size o be adapted for building purposes, whether it be standing n the forest or after it is felled. While the timber forms portion of the growing tree, it is distinguished as " standng timber;" when felled, it is called " rough timber." Afer the rough log is converted, that is, sawn into the forms or which it appears best adapted, the various conversions, s the produce is called, are designated according either to heir shape or their dimensions, as sided timber, balk, thicktuff, plank, or board. These several terms will be advertd to in a more advanced portion of this article, where they ill either be defined or incidentally explained.

Timber is of such incalculable value as the material for ie construction of our fleets, and it ministers also so rgely and in such numerous forms to our every-day ants, that it is not surprising the best means for its sucessful cultivation should have occupied much of the attenion of enlightened horticulturists; while it is certainly a ubject of much wonder, and has been occasionally one ausing no little anxiety, that the maintenance of an adeuate supply should be almost wholly left to accident, and at it consequently should be greatly neglected.

The species of timber which are chiefly used for buildg are oak and fir. Our supply of fir is for the greater rt drawn from abroad, as the climate of Great Britain oes not appear to be favourable to the growth of the est varieties of this species of timber; but with oak the ase is different. There is no doubt that England was iginally, almost from one extremity to the other, covered ith forests, in which the oak predominated; and peraps the best oak in the world is indigenous to England. Ve learn from the Doomsday-Book, that even in the eign of William the Conqueror, timber was so plentiful at the woods were not valued according to the quantity anding in them, nor according to the quantity which might e annually felled. In fact, the woods, as timber, were comaratively valueless, and their worth was estimated by the umber of swine which could be supported by the acorns. t present the produce of oak from our forests is not in y adequate proportion to the demand for it; and we are bliged to resort to foreign markets for this useful timer, or for substitutes. This is to be regretted, because ndoubtedly it is very desirable that we should be indepenent of other nations for our supplies of so important a comonent of our naval supremacy; and it is the more desirble, because in general the substitutes which we are able procure are not equal in quality to the produce of our wn soil. The oak of Great Britain is, for ship-building specially, superior to most timber which we can thus obain. The reason that the maintenance of the supply of ak timber does not meet with the attention which is reuired by the demand for it, evidently is, that although the emand is present and urgent, the advantages to be derived y any attempt to provide a supply are too prospective to mpt the cupidity of individual speculators. The home suply is therefore almost wholly left to be provided by those ho have a hereditary interest in the produce of the soil, e great landholders. There are, it is true, large tracts of nd which, as royal forests, are available for the services of he state; but it is only within a recent period that sufficient ttention has been paid to planting them, while the enormous emand for oak timber during the late long naval war had ompletely exhausted the stock which was previously growg upon them. It may not be deemed irrelevant to state e extent of this forest-land; at the same time premising, at there is much of it which is but ill adapted for the growth of good timber. The following account of these forests is taken from the Seventh Report of the Commissioners of Lands Revenue. It states the extent of the land in which the timber belongs to the crown in each of the forests to be:—

	Acres.	R.	P.
In New Forest	66,942	3	26
Dean	23,015	3	29
Aliceholt and Woolmer	8,694	1	31
Whittlewood	4,850	3	32
Salsey	1,847	0	23
Whichwood	3,709	3	5
Waltham	3,273	3	2
Sherwood	1,466	3	10
Bere	926	2	13
Sulehay Walk in Rockingham Forest	860	3	23
	115,594	0	34

" Of which total quantity about 70,000 acres are fit for the growth of oak timber." The Report also gives a statement, which we shall quote, as forming a criterion, founded on authority, to judge of the produce of forest-land: " If 700 acres, or $\frac{1}{100}$, of this land were enclosed and planted every year, until the whole 70,000 acres shall be completed, they will, if kept under proper management, furnish a perpetual supply of at least 35,000 loads of oak timber annually, from the time that the first planted trees arrive at 100 years growth." Table V. will give a good idea of the enormous consumption of timber which is entailed upon us by the extent of our navy. It may also be observed, that since the alterations in the system of registry at Lloyd's, merchant-ships consume nearly as much timber in their construction as ships of war of similar burthens.

The effect of the gradual destruction of the forests is a question of a speculative nature; a question too speculative, and involving consequences too far distant from our own time, to admit of discussion in this article: still it may be thus casually adverted to, because it is not a stretch of the imagination to suppose the time must arrive when the forests which furnish the present supplies will be exhausted by the unceasing and increasing demand upon them, and by the rapid spread of population. But a very few years have passed since it was comparatively easy to procure fir trees from the north of Europe, of sufficient size to make topmasts for the largest classes of men of war. Now there are no trees from thence to be purchased which will make such topmasts. Until about thirty-five or forty years ago Riga inch-masts were to be obtained as large as twenty-five inches in diameter. At that time, from the increased difficulty in procuring them, Canada yellow-pine sticks were substituted, which could then be got with ease as large as thirty inches in diameter; but now it very rarely happens that a stick of larger diameter than from twenty-five to twenty-seven inches is imported, and even this timber of these sizes is gradually becoming more scarce. Until lately timber of sufficient scantling to make stern-posts for the largest ships was to be procured; now such logs are not in the market.

The first English writer on timber was the celebrated Evelyn, who published his " Sylva, or Discourse of Forest Trees," in 1664. This book still continues one of the standard works on the subject in our language. In 1774 a new edition of it, with most extensive notes, and also engravings of the trees mentioned in the text, was published by the celebrated Dr Alexander Hunter of York. The last edition with these notes was published in 1825. In

France the two celebrated philosophers Buffon and Du Hamel have both devoted a great portion of their useful lives to the investigation of the physiology of timber, and their writings on the subject have long been the text-books of arborists. In modern times the phenomena of the growth of plants have occupied the attention of many men, some of whom have eminently distinguished themselves in this particular branch of natural history, and to whose works we shall have occasion to refer in the course of this article. The master-mind, however, in these researches, and the one whose indefatigable labours have left but few of the mysteries of vegetable physiology undeveloped, is Mr Knight, who was for several years president of the Horticultural Society, and whose valuable papers on the growth of plants in the Philosophical Transactions leave little scope for further investigation on several of the most important questions.

Botanists divide plants into two classes; exogenous, which are those that increase in their growth by an annual accession of matter externally; and endogenous, which are those that increase in their growth by an annual accession of matter internally: therefore in exogenous plants the external parts are the younger; and in the endogenous it is, on the contrary, the internal parts which are of the latest growth. It is almost entirely of the exogenous plants that we shall have occasion to treat in this article, the whole of the timber trees classing under that head.

The horizontal section of the stem of a plant of this description shows the perfect or heart wood occupying the central and larger portion of the area of the section. This wood must evidently, from what has been already stated, be of the oldest growth in the centre of the tree, and the several concentric layers must be younger in proportion to their distances from this centre. Around this perfect wood there is seen a concentric belt of yet younger growth; so young as not yet to have attained to the maturity of the perfect wood. This belt is called the alburnum or sap-wood; around it is another concentric belt, called the liber; and this again is enclosed in the bark, or cortical substance, the liber forming an internal coating to the bark. The centre of the heart-wood is occupied by the pith; and there is a communication between the pith and the bark, that is maintained by what are called the medullary rays, which, as their name expresses, radiate from the pith, in the centre of the perfect wood, to the external coating of the tree, the bark. The outer covering of the bark is sometimes called the epidermis.
